Let B_1 be the strict localization of $B[x/y]$ at the maximal ideal generated by $(\operatorname{rad} B, x/y)$. For each closed point Q of the closed fiber of Spec $B[y/x] \to$ Spec B, let A_Q denote the strict localization of $B[y/x]$ at Q, and let U_Q be the affine open subset of Spec A_Q that is the inverse image of U.

632 LEMMA 7.5. *To prove 7.1 for the ring B, it suffices to prove that for $q > d (\geq 2)$ we have*

(i) $$H^q(\operatorname{Spec} B_1[y/x], \mathbf{Z}/\ell) = 0$$

and

(ii) $$H^q(U_Q, \mathbf{Z}/\ell) = 0 \quad \textit{for each } Q.$$

Proof. We have open immersions

$$U \hookrightarrow \operatorname{Spec} B[1/x] \hookrightarrow \operatorname{Spec} B[y/x],$$

and hence a diagram

$$\begin{array}{ccc} U & \xrightarrow{\ i\ } & \operatorname{Spec} B[y/x] \\ & {\scriptstyle k}\searrow \quad \swarrow{\scriptstyle j} & \\ & Z & \end{array}.$$

If Q is a closed point of the closed fiber of Spec $B[y/x] \to$ Spec B, we have $(R^q i_* \mathbf{Z}/\ell)_Q = 0$ if $q > d$, by hypothesis. For each point P of Spec $B[y/x]$ which is not closed in the closed fiber of Spec $B[y/x] \to$ Spec B, we have $\delta(F, i, P) < d$, where $F = (\mathbf{Z}/\ell)_U$ (notation of (6.0)). Thus, applying the induction hypothesis and 6.1 to the morphism i, we find that for the morphism Spec $B[y/x] \to$ Spec B we have

$$(R^q i_* \mathbf{Z}/\ell) \leq d - q.$$

Consequently, the induction hypothesis in the form 6.1 bis, applied to the latter morphism, implies that

$$H^p(\text{Spec } B[y/x], R^q i_* \mathbf{Z}/\ell) = 0$$

if $q > 0$ and $p > d - q$. With the Leray spectral sequence 633

$$E_2^{pq} = H^p(\text{Spec } B[y/x], R^q i_* \mathbf{Z}/\ell) \Longrightarrow H^{p+q}(U, \mathbf{Z}/\ell).$$

we are reduced, in proving 7.1, to proving that

$$H^p(\text{Spec } B[y/x], i_* \mathbf{Z}/\ell) = 0 \quad \text{if} \quad p > d.$$

We have an exact sequence

$$0 \longrightarrow \mathbf{Z}/\ell \longrightarrow i_*(\mathbf{Z}/\ell)_U \longrightarrow C \longrightarrow 0 \tag{7.6}$$

where $\delta(C) < d$. It therefore suffices (again by induction) to prove that

$$H^p(\text{Spec } B[y/x], \mathbf{Z}/\ell) = 0 \quad \text{if} \quad p > d. \tag{7.7}$$

Now the open immersion Spec $B[y/x] \xrightarrow{j} Z$ is obtained by removing from Z the closed subset C "at infinity," and in the other open subset Spec $B[x/y]$ of Z it is identified with the open subset $C = V(x/y)$. The $R^q j_* \mathbf{Z}/\ell$ are concentrated on C, and the morphism $C \to$ Spec B is a closed immersion. Consequently, we have $H^p(Z, R^q j_* \mathbf{Z}/\ell) = 0$ if p and $q > 0$. Since the closed fiber of $Z \to$ Spec B has dimension 1 and this morphism is proper, XII 5.3 bis implies that $H^p(Z, j_* \mathbf{Z}/\ell) = 0$ if $p > 2$. The spectral sequence

$$E_2^{pq} = H^p(Z, R^q j_* \mathbf{Z}/\ell) \Longrightarrow H^{p+q}(\text{Spec } B[y/x], \mathbf{Z}\ell)$$

therefore gives isomorphisms

$$H^q(\text{Spec } B[y/x], \mathbf{Z}/\ell) \simeq H^0(Z, R^q j_* \mathbf{Z}/\ell) \simeq (R^q j_* \mathbf{Z}/\ell)_P$$

if $q > 2$, where P is the point "at infinity" of Z. These stalks are none other (VIII 5) than 634

$$(R^q j_* \mathbf{Z}/\ell)_P \simeq H^q(\text{Spec } B_1[y/x], j_* \mathbf{Z}/\ell).$$

By (7.7), it therefore suffices to prove that these latter groups vanish if $q > d$ (≥ 2). We have an exact sequence analogous to (7.6) which, together with the induction hypothesis, shows that it suffices that

$$H^q(\text{Spec } B_1[y/x], \mathbf{Z}/\ell) = 0 \quad \text{if} \quad q > d,$$

whence the lemma.

Proof of 7.5 (i).

Consider the closed subset $C = V(x/y)$ of Spec $B[x/y]$, with its induced reduced structure. It is immediate that the closed immersion of C into Spec B induced by the morphism $Z \to$ Spec B identifies C with the closed subscheme $X = \bigcup X_i$ of Spec B. Since

$$D(x) = \sum r_i X_i$$
$$D(y) = \sum (r_i - 1) X_i + \Gamma,$$

the element x/y generates the ideal $\mathfrak{J}(X_i)$ locally at the generic point of X_i, where the local ring is a discrete valuation ring because B is normal. Consequently, the morphism Spec $B[x/y] \to$ Spec B is an isomorphism in a neighborhood of such a point, and the element x/y vanishes to order 1 on each of the irreducible components C_i (corresponding to X_i) of C. 635

Since the closed subset C lifts to Spec B_1, this remains true if the ring $B[x/y]$ is replaced by B_1, and hence $B_1/(x/y)$ is a *complete* ring which is a formally separable k-algebra.

To prove 7.5 (i), we may first apply 4.3, which allows us to replace B_1 by its completion $\widehat{B}_1$, without affecting the ring $B_1/(x/y)$. By (7.2), we may moreover replace $\widehat{B}_1$ by its normalization $\overline{B}_1$. Since B_1 (and hence $\widehat{B}_1$) is already regular at the generic points of the C_i, the morphism Spec $\overline{B}_1 \to$ Spec $\widehat{B}_1$ is an isomorphism at these points, and so $\overline{B}_1/(x/y)$ is still a formally separable k-algebra. We are thus reduced to the special case 6.7 (ii), which proves the result.

Proof of 7.5 (ii).

Choose the point Q of the closed fiber of Spec $B[y/x] \to$ Spec B. The strict localization A_Q may be written as a limit

$$A_Q = \varinjlim A$$

where A ranges over a filtered category of rings that are étale and of finite type over $B[y/x]$. Let U_A be the affine open subset of Spec A that is the inverse image of U. Since x is invertible on U_A, the morphism $U_A \to$ Spec B is étale, and U_A is normal. Consequently, if C denotes the normalization of B in the field $R(A)$ of rational functions on A, we have an open immersion

$$U_A \longrightarrow \text{Spec } C.$$

636 It suffices (VII 5.7) to prove that for each A, the image of $H^q(U_A, \mathbf{Z}/\ell)$ in $H^q(U_Q, \mathbf{Z}/\ell)$ is zero if $q > d$. Since x is invertible on U_Q, the morphism $U_Q \to$ Spec A factors through Spec $A[1/f]$, if $f \in B$ is any element such that f is divisible by x in $B[y/x]$ and f/x does not vanish at the point Q. It thus suffices to prove that for a suitable such f, we have

$$H^q(U_{A,f}, \mathbf{Z}/\ell) = 0 \quad \text{if} \quad a > d,$$

where $U_{A,f} = U_A - V(f)$ is the affine open subset of Spec $A[1/f]$, which is also an affine open subset of Spec C.

Let $c \in k$ be an element such that $y/x + c$ does not vanish at Q, and let J be the ideal in B of the closed subset $\Gamma \cap X$. Then if

$$f \equiv y + cx (\text{mod } J^N) \quad N > 0, \tag{7.8}$$

the element f satisfies the condition above: Indeed, it is immediate that in Spec $B[y/x]$ we have $V(J) = V(x)$. Thus (7.8) does imply that f is divisible by x, whence

$$f/x \equiv y/x + c (\text{mod } J).$$

Since J vanishes at Q, and $y/x + c$ is nonzero at Q, this proves our assertion.

Now $\Gamma \cap X$ is a closed subset of Spec B of codimension 2. Consequently, we can
637 choose an f satisfying (7.8), call it z, such that $V(z) \cap V(y)$ is likewise of codimension 2. Also choose elements $x_3, \ldots, x_d$ such that $y, z, x_3, \ldots, x_d$ form a system of parameters of the ring B. Then B, and hence C as well, is a finite $k[[y, z, x_3, \ldots, x_d]]$-algebra.

Let C^0 be the normalization of $k[[y, z, x_3, \ldots, x_d]]$ in the separable closure of $k((y, z, x))$ in the field of rational functions $R(C)$, so that C is a radicial extension of C^0, and C^0 is a generically étale extension of $k((y, z, x))$ (where $x = x_3, \ldots, x_d$).

Choose a linear combination

$$f = az + by \quad (a, b \in k),$$

such that the morphism

$$\operatorname{Spec} C^0 \longrightarrow \operatorname{Spec} k[[z, y, x]]$$

is étale over the generic point of $V(f)$, and such that f/x does not vanish at Q in $\operatorname{Spec} B[y/x]$. It suffices to prove that

$$H^q(U_{A,f}, \mathbf{Z}/\ell) = 0 \quad \text{if} \quad q > d,$$

and hence (VIII 1.1) to prove that

$$H^q(U^0_{A,f}, \mathbf{Z}/\ell) = 0 \quad \text{if} \quad q > d,$$

where $U^0_{A,f}$ is the open subset of $\operatorname{Spec} C^0$ corresponding to the open subset $U_{A,f}$ of $\operatorname{Spec} C$, which is affine, as follows by descent (EGA IV 2.7.1 (xiii)). But by construction, the element f of C^0 is invertible on $U^0_{A,f}$, and $C^0/(f)$ is a formally separable k-algebra. We are therefore in the situation of 6.7 (ii), which completes the proof of 7.5 (ii), and hence that of 6.1.

Chapter 1

Étale cohomology: the starting points

1 Grothendieck topologies

Grothendieck topologies first appeared as the foundation of Grothendieck's theory of descent (cf. SGA 1 VI, VIII); their use in the corresponding cohomology theories came later. We follow the same path here: by formalizing the classical notions of localization, local property, and patching (1.1, 1.2, 1.3), we obtain the general concept of a Grothendieck topology (1.6); to justify its introduction into algebraic geometry, we prove a faithfully flat descent theorem (1.4), generalizing the classical theorem 90 of Hilbert (1.5).

The reader will find a more complete, but concise, exposition of the formalism in Giraud [19]. M. Artin's notes, "Grothendieck topologies" [1] (Chapters I to III), also remain useful. The 866 pages of Exposés I to V of SGA 4 are valuable when one considers exotic topologies, such as the one giving rise to crystalline cohomology; in order to use the étale topology, which is so close to classical intuition, it is not essential to read them.

1.1 Sieves

Let X be a topological space and let $f : X \to \mathbb{R}$ be a real-valued function on X. The continuity of f is a local property; in other words, if f is continuous on every sufficiently small open subset of X, then f is continuous on all of X. To formalize the notion of a "local property," we introduce some definitions.

A set $\mathcal{U}$ of open subsets of X is called a *sieve* if, for every $U \in \mathcal{U}$ and $V \subset U$, one has $V \in \mathcal{U}$. A sieve is called *covering* if the union of all the open subsets belonging to it is equal to X.

Given a family $\{U_i\}$ of open subsets of X, the sieve generated by $\{U_i\}$ is, by definition, the set of open subsets U of X such that U is contained in one of the U_i.

A property $P(U)$, defined for every open subset U of X, is called *local* if, for every covering sieve $\mathcal{U}$ of every open subset U of X, $P(U)$ is true if and only if $P(V)$ is true for every $V \in \mathcal{U}$. For example, given $f : X \to \mathbb{R}$, the property "f is continuous on U" is local.

1.2 Sheaves

Let us make precise the notion of a function given locally on X.

by P. Deligne, written up by J.F. Boutot

1.2.1 The sieve point of view

Let $\mathcal{U}$ be a sieve of open subsets of X. A function given $\mathcal{U}$-locally on X consists of a function f_U on U for every $U \in \mathcal{U}$, such that if $V \subset U$ then $f_V = f_U|V$.

1.2.2 The Čech point of view

If the sieve $\mathcal{U}$ is generated by a family of open subsets U_i of X, then giving a function $\mathcal{U}$-locally amounts to giving a function f_i on each U_i such that $f_i|U_i \cap U_j = f_j|U_i \cap U_j$.

In other words, if $Z = \coprod U_i$, then giving a function $\mathcal{U}$-locally amounts to giving a function on Z that is constant on the fibres of the natural projection $Z \to X$.

1.2.3

The continuous functions form a sheaf. This means that for every covering sieve $\mathcal{U}$ of an open subset V of X, and every function $\{f_U\}$ given $\mathcal{U}$-locally such that each f_U is continuous on U, there exists a unique continuous function f on V such that $f|U = f_U$ for every $U \in \mathcal{U}$.

1.3 Stacks

Let us now make precise the notion of a vector bundle given locally on X.

1.3.1 The sieve point of view

Let $\mathcal{U}$ be a sieve of open subsets of X. A vector bundle given $\mathcal{U}$-locally on X consists of

a) a vector bundle E_U on each $U \in \mathcal{U}$,

b) if $V \subset U$, an isomorphism $\rho_{U,V} : E_V \xrightarrow{\sim} E_U|V$, satisfying

c) if $W \subset V \subset U$, the diagram

$$\begin{array}{ccc} E_W & \xrightarrow{\rho_{U,W}} & E_U|W \\ & \searrow^{\rho_{V,W}} & \uparrow{\scriptstyle \rho_{U,V}|W} \\ & & E_V|W \end{array}$$

commutes, that is, $\rho_{U,V} = (\rho_{U,V}$ restricted to $W) \circ \rho_{V,W}$.

1.3.2 The Čech point of view

If the sieve $\mathcal{U}$ is generated by a family of open subsets U_i of X, then giving a vector bundle $\mathcal{U}$-locally amounts to giving:

a) a vector bundle E_i on each U_i,

b) if $U_{ij} = U_i \cap U_j = U_i \times_X U_j$, an isomorphism $\rho_{ji} : E_i|U_{ij} \xrightarrow{\sim} E_j|U_{ij}$, such that

c) if $U_{ijk} = U_i \times_X U_j \times_X U_k$, the diagram

$$\begin{array}{ccc} E_i|U_{ijk} & \xrightarrow{\rho_{ki}|U_{ijk}} & E_k|U_{ijk} \\ & \searrow^{\rho_{ji}|U_{ijk}} & \uparrow{\scriptstyle \rho_{kj}|U_{ijk}} \\ & & E_j|U_{ijk} \end{array}$$

commutes, that is, $\rho_{ki} = \rho_{kj} \circ \rho_{ji}$ on U_{ijk}.

In other words, if $Z = \coprod U_i$ and $\pi : Z \to X$ is the natural projection, then giving a vector bundle $\mathcal{U}$-locally amounts to giving:

a) a vector bundle E on Z,

b) if x and y are two points of Z such that $\pi(x) = \pi(y)$, an isomorphism $\rho_{yx} : E_x \xrightarrow{\sim} E_y$ between the fibres of E at x and y, depending continuously on (x, y), and such that

c) if x, y, and z are three points of Z such that $\pi(x) = \pi(y) = \pi(z)$, then $\rho_{zx} = \rho_{zy} \circ \rho_{yx}$.

1.3.3

A vector bundle E on X defines a vector bundle $E_{\mathcal{U}}$ given $\mathcal{U}$-locally, namely the system of restrictions E_U of E to the objects of $\mathcal{U}$. The fact that the notion of a vector bundle is local can be expressed as follows: for every covering sieve $\mathcal{U}$ of X, the functor $E \mapsto E_{\mathcal{U}}$ from vector bundles on X to vector bundles given $\mathcal{U}$-locally is an equivalence of categories.

1.3.4

If in 1 one replaces "open subset of X" by "subset of X," one obtains the notion of a sieve of subspaces of X. In this setting there are also patching theorems. For example, let X be a space and let $\mathcal{C}$ be a sieve of subspaces of X generated by a locally finite closed covering of X. Then the functor $E \mapsto E_{\mathcal{C}}$ from vector bundles on X to vector bundles given $\mathcal{C}$-locally is an equivalence of categories.

In algebraic geometry, it is also useful to consider "sieves of spaces over X"; this is what we shall see in the next paragraph.

1.4 Faithfully flat descent

1.4.1

In the setting of schemes, the Zariski topology is not fine enough for the study of nonlinear problems, and one is led to replace the open immersions in the preceding definitions by more general morphisms. From this point of view, descent techniques appear as localization techniques. Thus the following descent statement can be expressed by saying that the properties under consideration are local for the faithfully flat topology (a morphism of schemes is called faithfully flat if it is flat and surjective).

Proposition 1.4.2. *Let A be a ring and B a faithfully flat A-algebra. Then:*

(i) A sequence $\Sigma = (M' \to M \to M'')$ of A-modules is exact if the sequence $\Sigma_{(B)}$ deduced from it by extension of scalars to B is exact.

(ii) An A-module M is of finite type (resp. of finite presentation, flat, locally free of finite rank, invertible (i.e. locally free of rank one)) if the B-module $M_{(B)}$ has the corresponding property.

Proof. (i) Since the functor $M \mapsto M_{(B)}$ is exact (by flatness of B), it suffices to show that if an A-module N is nonzero, then $N_{(B)}$ is nonzero. If N is nonzero, N contains a nonzero cyclic submodule $A/\mathfrak{a}$; hence $N_{(B)}$ contains the cyclic submodule $(A/\mathfrak{a})_{(B)} = B/\mathfrak{a}B$, which is nonzero by surjectivity of the structural morphism $\varphi : \mathrm{Spec}(B) \to \mathrm{Spec}(A)$ (if $V(\mathfrak{a})$ is nonempty, then $\varphi^{-1}(V(\mathfrak{a})) = V(\mathfrak{a}B)$ is nonempty).

(ii) For every family (x_i) of elements of $M_{(B)}$, there exists a finitely generated submodule M' of M such that $M'_{(B)}$ contains the x_i. If $M_{(B)}$ is of finite type and the x_i generate $M_{(B)}$, then $M'_{(B)} = M_{(B)}$, and hence $M' = M$ and M is of finite type. □

If $M_{(B)}$ is of finite presentation, the preceding argument yields a surjection $A^n \to M$. If N is the kernel of this surjection, then the B-module $N_{(B)}$ is of finite type, so N is of finite type and M is of finite presentation. The assertion for "flat" follows at once from (i); "locally free of finite rank" means "flat and of finite presentation," and the rank can be tested after extension of scalars to fields.

1.4.3

Let X be a scheme and let $\mathcal{S}$ be a class of X-schemes stable under fibre products over X. A class $\mathcal{U} \subset \mathcal{S}$ is a *sieve* on X (relative to $\mathcal{S}$) if, for every morphism $\varphi : V \to U$ of X-schemes with $U, V \in \mathcal{S}$ and $U \in \mathcal{U}$, one has $V \in \mathcal{U}$. The sieve *generated* by a family $\{U_i\}$ of X-schemes in $\mathcal{S}$ is the class of $V \in \mathcal{S}$ for which there exists a morphism of X-schemes from V to one of the U_i.

1.4.4

Let $\mathcal{U}$ be a sieve on X. A quasi-coherent module given $\mathcal{U}$-locally on X consists of

a) a quasi-coherent module E_U on every $U \in \mathcal{U}$,

b) for every $U \in \mathcal{U}$ and every morphism $\varphi : V \to U$ of X-schemes in $\mathcal{S}$, an isomorphism $\rho_\varphi : E_V \xrightarrow{\sim} \varphi^* E_U$, such that

c) if $\psi : W \to V$ is a morphism of X-schemes in $\mathcal{S}$, the diagram

$$\begin{array}{ccc} E_W & \xrightarrow{\rho_{\varphi\circ\psi}} & \psi^*\varphi^* E_U \\ & \searrow^{\rho_\psi} & \uparrow{\scriptstyle \psi^*\rho_\varphi} \\ & & \psi^* E_V \end{array}$$

commutes, that is, $\rho_{\varphi\circ\psi} = (\psi^*\rho_\varphi) \circ \rho_\psi$.

If E is a quasi-coherent module on X, we write $E_{\mathcal{U}}$ for the module given $\mathcal{U}$-locally whose value is $\varphi_U^* E$ on $\varphi : U \to X$ and such that, for every morphism $\psi : V \to U$, the restriction isomorphism ρ_ψ is the canonical isomorphism $E_V = (\varphi_U \circ \psi)^* E \xrightarrow{\sim} \psi^* \varphi_U^* E = \psi^* E_U$.

Theorem 1.4.5. *Let $\{U_i\} \in \mathcal{S}$ be a finite family of X-schemes flat over X such that X is the union of the images of the U_i, and let $\mathcal{U}$ be the sieve generated by $\{U_i\}$. Then the functor $E \mapsto E_{\mathcal{U}}$ is an equivalence from the category of quasi-coherent modules on X to the category of quasi-coherent modules given $\mathcal{U}$-locally.*

Proof. We treat only the case in which x is affine and $\mathcal{U}$ is generated by an affine X-scheme U faithfully flat over X. The reduction to this case is formal. Put $X = \mathrm{Spec}(A)$ and $U = \mathrm{Spec}(B)$.

If $U \to X$ admits a section, then X belongs to the sieve $\mathcal{U}$ and the assertion is clear. We reduce to this case.

A quasi-coherent module given $\mathcal{U}$-locally defines modules M', M'', and M''' on U, $U \times_X U$, and $U \times_X U \times_X U$, and isomorphisms $\rho : p^*M^\bullet \simeq M^\bullet$ for every projection morphism p between these spaces; this is a *cartesian diagram*

$$M^* : M' \rightrightarrows M'' \;\substack{\rightarrow\\ \rightarrow\\ \rightarrow}\; M'''$$

over

$$U_* : U \;\substack{\leftarrow\\ \leftarrow}\; U \times_X U \;\substack{\leftarrow\\ \leftarrow\\ \leftarrow}\; U \times_X U \times_X U.$$

Conversely, M^* determines the module given $\mathcal{U}$-locally: for $V \in \mathcal{U}$ there exists $\varphi : V \to U$, and we put $M_U = \varphi^* M'$; for $\varphi_1, \varphi_2 : V \to U$ there is a natural identification $\varphi_1^* M' \simeq (\varphi_1 \times \varphi_2)^* M'' \simeq \varphi_2^* M'$, and by using M''' one sees that these identifications are compatible, so the definition is legitimate. In short, giving a module $\mathcal{U}$-locally is equivalent to giving a cartesian diagram M^* over U_*.

In algebraic terms, giving M^* amounts to giving a cartesian diagram of modules

$$M' \;\substack{\xrightarrow{\partial_0}\\ \xrightarrow{\partial_1}}\; M'' \;\substack{\xrightarrow{\partial_0}\\ \xrightarrow{\partial_1}\\ \xrightarrow{\partial_2}}\; M'''$$

over the diagram of rings

$$B \;\substack{\xrightarrow{\partial_0}\\ \xrightarrow{\partial_1}}\; B \otimes_A B \;\substack{\xrightarrow{\partial_0}\\ \xrightarrow{\partial_1}\\ \xrightarrow{\partial_2}}\; B \otimes_A B \otimes_A B$$

(more precisely, $\partial_i(bm) = \partial_i(b) \cdot \partial_i(m)$, the usual identities such as $\partial_0\partial_1 = \partial_0\partial_0$ hold, and "cartesian" means that the morphisms $\partial_i : M' \otimes_{B,\partial_i} (B \otimes_A B) \to M''$ and $M'' \otimes_{B\otimes_A B,\partial_i} (B \otimes_A B \otimes_A B) \to M'''$ are isomorphisms).

The functor $E \mapsto E_{\mathcal{U}}$ becomes the functor that associates to an A-module M the diagram

$$M^* = (M \otimes_A B \rightrightarrows M \otimes_A B \otimes_A B \;\substack{\rightarrow\\ \rightarrow\\ \rightarrow}\; M \otimes_A B \otimes_A B \otimes_A B).$$

Its right adjoint is the functor

$$(M' \rightrightarrows M'' \;\substack{\rightarrow\\ \rightarrow\\ \rightarrow}\; M''') \longmapsto \ker(M' \rightrightarrows M''').$$

We must prove that the adjunction maps

$$M \to \ker(M \otimes_A B \rightrightarrows M \otimes_A B \otimes_A B)$$

and

$$\ker(M' \rightrightarrows M'') \otimes_A B \to M'$$

are isomorphisms. By (1.4.2.i), it suffices to prove this after a faithfully flat base change $A \to A'$ (with B becoming $B' = B \otimes_A A'$). Taking $A' = B$ reduces us to the case in which $U \to X$ admits a section. □

1.5 A special case: Hilbert's theorem 90

1.5.1

Let k be a field, let k' be a Galois extension of k, and let $G = \mathrm{Gal}(k'/k)$. Then the homomorphism

$$\begin{aligned} k' \otimes_k k' &\to \oplus_{\sigma \in G} k' \\ x \otimes y &\mapsto \{x \cdot \sigma(y)\}_{\sigma \in G} \end{aligned}$$

is bijective.

It follows that giving a module locally for the sieve on $\mathrm{Spec}(k)$ generated by $\mathrm{Spec}(k')$ is equivalent to giving a k'-vector space equipped with a semilinear action of G, that is:

a) a k'-vector space V',

b) for every $\sigma \in G$, an endomorphism φ_σ of the underlying group of V' such that $\varphi_\sigma(\lambda v) = \sigma(\lambda)\varphi_\sigma(v)$ for all $\lambda \in k'$ and $v \in V'$, satisfying the condition

c) for all $\sigma, \tau \in G$, $\varphi_{\tau\sigma} = \varphi_\tau \circ \varphi_\sigma$.

Let $V = V'^G$ be the group of invariants under this action of G. It is a k-vector space, and by Theorem 1.4.5 one has:

Proposition 1.5.2. *The inclusion of V in V' defines an isomorphism $V \otimes_k k' \xrightarrow{\sim} V'$.*

In particular, if V' has dimension 1 and $v' \in V$ is nonzero, then φ_σ is determined by the constant $c(\sigma) \in k'^\times$ such that $\varphi_\sigma(v') = c(\sigma)v'$, and condition c) becomes

$$c(\tau\sigma) = c(\tau) \cdot \tau(c(\sigma)).$$

By the proposition, there exists a nonzero invariant vector $v = \mu v'$, $\mu \in k'^\times$. Hence, for every $\sigma \in G$,

$$c(\sigma) = \mu \cdot \sigma(\mu^{-1}).$$

In other words, every 1-cocycle of G with values in $k'^\times$ is a coboundary:

Corollary 1.5.3. *One has* $\mathrm{H}^1(G, k'^\times) = 0$.

1.6 Grothendieck topologies

We now transpose the definitions of the preceding paragraphs to an abstract setting that encompasses both topological spaces and schemes.

1.6.1

Let $\mathcal{S}$ be a category and let U be an object of $\mathcal{S}$. A *sieve* on U is a subset $\mathcal{U}$ of $\mathrm{Ob}(\mathcal{S}/U)$ such that if $\varphi : V \to U$ belongs to $\mathcal{U}$ and $\psi : W \to V$ is a morphism in $\mathcal{S}$, then $\varphi \circ \psi : W \to U$ belongs to $\mathcal{U}$.

If $\{\varphi_i : U_i \to U\}$ is a family of morphisms, the sieve generated by the U_i is, by definition, the set of morphisms $\varphi : V \to U$ that factor through one of the φ_i.

If $\mathcal{U}$ is a sieve on U and $\varphi : V \to U$ is a morphism, the restriction $\mathcal{U}_V$ of $\mathcal{U}$ to V is, by definition, the sieve on V consisting of the morphisms $\psi : w \to V$ such that $\varphi \circ \psi : W \to U$ belongs to $\mathcal{U}$.

1.6.2

A *Grothendieck topology* on $\mathcal{S}$ consists of the choice, for every object U of $\mathcal{S}$, of a set $C(U)$ of sieves on U, called covering sieves, such that the following axioms hold:

a) The sieve generated by the identity of U is covering.

b) If $\mathcal{U}$ is a covering sieve on U and $V \to U$ is a morphism, then the sieve $\mathcal{U}_V$ is covering.

c) A locally covering sieve is covering. In other words, if $\mathcal{U}$ is a covering sieve on U and $\mathcal{U}'$ is a sieve on U such that, for every $V \to U$ belonging to $\mathcal{U}$, the sieve $\mathcal{U}'_V$ is covering, then $\mathcal{U}'$ is covering.

A category equipped with a Grothendieck topology is called a *site*.

1.6.3

Given a site $\mathcal{S}$, a presheaf on $\mathcal{S}$ is a contravariant functor $\mathscr{F}$ from $\mathcal{S}$ to the category of sets. For every object U of $\mathcal{S}$, the elements of $\mathscr{F}(U)$ are called sections of $\mathscr{F}$ over U. For every morphism $V \to U$ and every $s \in \mathscr{F}(U)$, we denote by $s|V$ (s restricted to V) the image of s in $\mathscr{F}(V)$.

If $\mathcal{U}$ is a sieve on U, a section given $\mathcal{U}$-locally consists, for every $V \to U$ belonging to $\mathcal{U}$, of a section $s_V \in \mathscr{F}(V)$ such that, for every morphism $W \to V$, $s_V|W = s_W$. The presheaf $\mathscr{F}$ is called a *sheaf* if, for every object U of $\mathcal{S}$, every covering sieve $\mathcal{U}$ on U, and every section $\{s_V\}$ given $\mathcal{U}$-locally, there exists a unique section $s \in \mathscr{F}(U)$ such that $s|V = s_V$ for every $V \to U$ belonging to $\mathcal{U}$.

Abelian sheaves are defined similarly by replacing the category of sets with the category of abelian groups. One shows that the category of abelian sheaves on $\mathcal{S}$ is an abelian category with enough injectives. A sequence $\mathscr{F} \xrightarrow{f} \mathscr{G} \xrightarrow{g} \mathscr{H}$ of sheaves is exact if, for every object U of $\mathcal{S}$ and every $s \in \mathscr{G}(U)$ such that $g(s) = 0$, there exists locally a t such that $f(t) = s$; i.e. there exists a covering sieve $\mathcal{U}$ on U and, for every $V \in \mathcal{U}$, a section t_V of $\mathscr{F}$ on V such that $f(t_V) = s|V$.

1.6.4 Examples

We have seen two examples above.

a) Let X be a topological space and let $\mathcal{S}$ be the category whose objects are the open subsets of X and whose morphisms are the natural inclusions. The Grothendieck topology on $\mathcal{S}$ corresponding to the usual topology of X is the one for which a sieve $\mathcal{U}$ on an open subset U of X is covering if the union of the open subsets belonging to the sieve equals U. It is clear that the category of sheaves on $\mathcal{S}$ is equivalent to the category of sheaves on X in the usual sense.

b) Let X be a scheme and let $\mathcal{S}$ be the category of schemes over X. The fpqc (faithfully flat quasi-compact) topology on $\mathcal{S}$ is the Grothendieck topology for which a sieve on an X-scheme U is covering if it is generated by a finite family of flat morphisms whose images cover U.

1.6.5 Cohomology

We shall always assume that the category $\mathcal{S}$ has a final object X. The global sections of an abelian sheaf $\mathscr{F}$, denoted by $\Gamma\mathscr{F}$ or $\mathrm{H}^0(X, \mathscr{F})$, form the group $\mathscr{F}(X)$. The functor $\mathscr{F} \mapsto \Gamma\mathscr{F}$ is a left exact functor from the category of abelian sheaves on $\mathcal{S}$ to the category of abelian groups; its derived functors (or satellites) are denoted by $\mathrm{H}^i(X, -)$. These cohomology groups represent the obstructions to passing from the local to the global. By definition, if $0 \to \mathscr{F} \to \mathscr{G} \to \mathscr{H} \to 0$ is an exact sequence of abelian sheaves, then there is a long exact cohomology sequence:

$$0 \longrightarrow \mathrm{H}^0(X, \mathscr{F}) \longrightarrow \mathrm{H}^0(X, \mathscr{G}) \longrightarrow \mathrm{H}^0(X, \mathscr{H}) \longrightarrow \mathrm{H}^1(X, \mathscr{F}) \longrightarrow \cdots$$

$$\ldots \longrightarrow \mathrm{H}^n(X, \mathscr{F}) \longrightarrow \mathrm{H}^n(X, \mathscr{G}) \longrightarrow \mathrm{H}^n(X, \mathscr{H}) \longrightarrow \mathrm{H}^{n+1}(X, \mathscr{F}) \longrightarrow \cdots$$

1.6.6

Given an abelian sheaf $\mathscr{F}$ on $\mathcal{S}$, an *$\mathscr{F}$-torsor* is a sheaf $\mathscr{G}$ equipped with an action $\mathscr{F} \times \mathscr{G} \to \mathscr{G}$ of $\mathscr{F}$ such that locally (after restriction to all the objects of a covering sieve of the final object X), $\mathscr{G}$ with its $\mathscr{F}$-action is isomorphic to $\mathscr{F}$ with the canonical translation action $\mathscr{F} \times \mathscr{F} \to \mathscr{F}$.

One can show that $\mathrm{H}^1(X, \mathscr{F})$ may be interpreted as the set of isomorphism classes of $\mathscr{F}$-torsors.

2 The étale topology

We specialize the definitions of the preceding chapter to the étale topology of a scheme X (2.1, 2.2, 2.3). When X is the spectrum of a field K, the corresponding cohomology agrees with the Galois cohomology of K (2.4).

2.1 The étale topology

We begin by recalling some facts about étale morphisms.

Definition 2.1.1. *Let A be a (commutative) ring. An A-algebra B is called étale if B is an A-algebra of finite presentation and the following equivalent conditions hold:*

a) For every A-algebra C and every square-zero ideal J of C, the canonical map

$$\hom_{A\text{-alg}}(B, C) \to \hom_{A\text{-alg}}(B, C/J)$$

is a bijection.

b) B is a flat A-module and $\Omega_{B/A} = 0$ (where $\Omega_{B/A}$ denotes the module of relative differentials).

c) Let $B = A[X_1, \dots, X_n]/I$ be a presentation of B. Then, for every prime ideal $\mathfrak{p}$ of $A[X_1, \dots, X_n]$ containing I, there exist polynomials $P_1, \dots, P_n \in I$ such that $I_{\mathfrak{p}}$ is generated by the images of $P_1, \dots, P_n$ and $\det(\partial P_i/\partial X_j) \notin \mathfrak{p}$.

(cf. [23, I] or [30, V])

A morphism of schemes $f : X \to S$ is called *étale* if, for every $x \in X$, there exist an affine open neighbourhood $U = \mathrm{Spec}(A)$ of $f(x)$ and an affine open neighbourhood $V = \mathrm{Spec}(B)$ of x in $X \times_S U$ such that B is an étale A-algebra.

2.1.2 Examples

a) If A is a field, an A-algebra B is étale if and only if it is a finite product of separable extensions of A.

b) If X and S are schemes of finite type over $\mathbb{C}$, a morphism $f : X \to S$ is étale if and only if its analytification $f^{\mathrm{an}} : X^{\mathrm{an}} \to Y^{\mathrm{an}}$ is a local isomorphism.

2.1.3 Consequences

a) (base change) If $f : X \to S$ is an étale morphism, then so is $f_{S'} : X \times_S S' \to S'$ for every morphism $S' \to S$.

b) If $f : X \to S$ and $g : Y \to S$ are two étale morphisms, then every S-morphism from X to Y is étale.

c) (descent) Let $f : X \to S$ be a morphism. If there exists a faithfully flat morphism $S' \to S$ such that $f_{S'} : X \times_S S' \to S'$ is étale, then f is étale.

2.1.4

Let X be a scheme, and let $\mathcal{S}$ be the category of étale X-schemes. By (2.1.3.c), every morphism in $\mathcal{S}$ is étale. The *étale topology* on $\mathcal{S}$ is the topology for which a sieve on U is covering if it is generated by a finite family of morphisms $\varphi_i : U_i \to U$ such that the union of the images of the φ_i covers U. The *étale site* of X, denoted by X_{et}, is the site defined by $\mathcal{S}$ with the étale topology.

2.2 Examples of sheaves

2.2.1 Constant sheaf

Let C be an abelian group and, for simplicity, suppose that X is noetherian. We denote by $\underline{C}_X$ (or simply C if there is no ambiguity) the sheaf defined by $U \mapsto C^{\pi_0(U)}$, where $\pi_0(U)$ is the (finite) set of connected components of U. The most important case will be $C = \mathbb{Z}/n$. Thus, by definition,

$$\mathrm{H}^0(X, \mathbb{Z}/n) = (\mathbb{Z}/n)^{\pi_0(X)}.$$

Moreover, $\mathrm{H}^1(X, \mathbb{Z}/n)$ is the set of isomorphism classes of $\mathbb{Z}/n$-torsors (1.6.6), in other words, of finite Galois étale coverings of X with group $\mathbb{Z}/n$. In particular, if X is connected and $\pi_1(X)$ is its fundamental group for a chosen base point, then

$$\mathrm{H}^1(X, \mathbb{Z}/n) = \hom(\pi_1(X), \mathbb{Z}/n).$$

2.2.2 Multiplicative group

We denote by $\mathbb{G}_{m,X}$ (or $\mathbb{G}_m$ if there is no ambiguity) the sheaf defined by $U \mapsto \Gamma(U, \mathscr{O}_U^\times)$; it is indeed a sheaf by the faithfully flat descent theorem (1.4.5). By definition,

$$\mathrm{H}^0(X, \mathbb{G}_m) = \mathrm{H}^0(X, \mathscr{O}_X)^\times;$$

in particular, if X is reduced, connected, and proper over an algebraically closed field k, then

$$\mathrm{H}^0(X, \mathbb{G}_m) = k^\times.$$

Proposition 2.2.3. *There is an isomorphism*

$$\mathrm{H}^1(X, \mathbb{G}_m) = \mathrm{Pic}(X),$$

where $\mathrm{Pic}(X)$ *is the group of isomorphism classes of invertible sheaves on* X*.*

Proof. Let $*$ be the functor that associates to an invertible sheaf $\mathscr{L}$ on X the following presheaf $\mathscr{L}^*$ on X_{et}: for $\varphi : U \to X$ étale,

$$\mathscr{L}^*(U) = \mathrm{Isom}_U(\mathscr{O}_U, \varphi^*\mathscr{L}).$$

By (1.4.2.i) and (1.4.5) (full faithfulness), this presheaf is a sheaf; indeed, it is a $\mathbb{G}_m$-torsor. One checks immediately that

a) the functor $*$ is compatible with (étale) localization;

b) it induces an equivalence from the category of trivial invertible sheaves (i.e. isomorphic to $\mathscr{O}_X$) to the category of trivial $\mathbb{G}_m$-torsors: $\mathscr{L}$ is trivial if and only if $\mathscr{L}^*$ is trivial.

Moreover, by (1.4.2.ii) and (1.4.5),

c) the notion of an invertible sheaf is local for the étale topology.

It follows formally from a), b), and c) that $*$ is an equivalence between the category of invertible sheaves on X and that of $\mathbb{G}_m$-torsors on X_{et}; it induces the desired isomorphism. The inverse equivalence is constructed as follows. If $\mathscr{T}$ is a $\mathbb{G}_m$-torsor, there exists a finite étale covering $\{U_i\}$ of X such that the torsors $\mathscr{T}/U_i$ are trivial; $\mathscr{T}$ is then trivial on every V étale over X belonging to the sieve $\mathcal{U} \subset X_{\mathrm{et}}$ generated by $\{U_i\}$. On every $V \in \mathcal{U}$, $\mathscr{T}|V$ corresponds to an invertible sheaf $\mathscr{L}_V$ (by b)), and the $\mathscr{L}_V$ form an invertible sheaf given $\mathcal{U}$-locally, $\mathscr{L}_{\mathcal{U}}$ (by a)). By c), the latter comes from an invertible sheaf $\mathscr{L}(\mathscr{T})$ on X, and $\mathscr{T} \mapsto \mathscr{L}(\mathscr{T})$ is the desired inverse of $*$. □

2.2.4 Roots of unity

For every integer $n > 0$, the sheaf of nth roots of unity, denoted by $\boldsymbol{\mu}_n$, is the kernel of the nth-power map on $\mathbb{G}_m$. If X is a scheme over a separably closed field k and n is invertible in k, the choice of a primitive nth root of unity $\zeta \in k$ defines an isomorphism $i \mapsto \zeta^i$ from $\mathbb{Z}/n$ to $\boldsymbol{\mu}_n$.

The relation between cohomology with coefficients in $\boldsymbol{\mu}_m$ and cohomology with coefficients in $\mathbb{G}_m$ is given by the cohomology exact sequence deduced from the following theorem.

Theorem 2.2.5 (Kummer theory)**.** *If n is invertible on X, the nth-power map on $\mathbb{G}_m$ is an epimorphism of sheaves. Hence there is an exact sequence*

$$0 \to \boldsymbol{\mu}_n \to \mathbb{G}_m \to \mathbb{G}_m \to 0.$$

Proof. Let $U \to X$ be an étale morphism and let $a \in \mathbb{G}_m(U) = \Gamma(U, \mathscr{O}_U^\times)$. Since n is invertible on U, the equation $T^n - a = 0$ is separable; in other words, $U' = \operatorname{Spec}(\mathscr{O}_U[T]/(T^n - a))$ is étale over U. Moreover, $U' \to U$ is surjective and this element has an nth root on U', which proves the result. □

2.3 Fibres, direct images

2.3.1

A *geometric point* of X is a morphism $\bar{x} \to X$, where $\bar{x}$ is the spectrum of a separably closed field $k(\bar{x})$. By abuse of notation, we denote it by $\bar{x}$, leaving the morphism $\bar{x} \to X$ implicit. If x is the image of $\bar{x}$ in X, we say that $\bar{x}$ is centred at x. If $k(\bar{x})$ is an algebraic extension of the residue field $k(x)$, then $\bar{x}$ is called an *algebraic* geometric point of X.

An *étale neighbourhood* of $\bar{x}$ is a commutative diagram

$$\begin{array}{ccc} & & U \\ & \nearrow & \downarrow \\ \bar{x} & \longrightarrow & X, \end{array}$$

where $U \to X$ is étale.

The *strict localization* of X at $\bar{x}$ is the ring $\mathscr{O}_{X,\bar{x}} = \varinjlim \Gamma(U, \mathscr{O}_U)$, where the direct limit is taken over the étale neighbourhoods of $\bar{x}$. It is a strictly henselian local ring whose residue field is the separable closure in $k(\bar{x})$ of the residue field $k(x)$ of X at x. It plays the role of the local ring for the étale topology.

2.3.2

Given a sheaf $\mathscr{F}$ on X_{et}, the *fibre* of $\mathscr{F}$ at $\bar{x}$ is the set (resp. group, ...) $\mathscr{F}_{\bar{x}} = \varinjlim \mathscr{F}(U)$, where the direct limit is again taken over the étale neighbourhoods of X.

A homomorphism of sheaves $\mathscr{F} \to \mathscr{G}$ is a mono-/epi-/isomorphism if and only if the induced morphisms $\mathscr{F}_{\bar{x}} \to \mathscr{G}_{\bar{x}}$ on fibres have the corresponding property at every geometric point of X. If X is of finite type over an algebraically closed field, it suffices that this hold at the rational points of X.

2.3.3

If $f : X \to Y$ is a morphism of schemes and $\mathscr{F}$ is a sheaf on X_{et}, the *direct image* $f_*\mathscr{F}$ of $\mathscr{F}$ under f is the sheaf on Y_{et} defined by $f_*\mathscr{F}(V) = \mathscr{F}(X \times_Y V)$ for every V étale over Y. The functor $f_* : \operatorname{Sh}(X_{\text{et}}) \to \operatorname{Sh}(Y_{\text{et}})$

is left exact. Its right derived functors $\mathsf{R}^q f_*$ are called the higher direct images. If $\bar{y}$ is a geometric point of Y, then

$$(\mathsf{R}^q f_* \mathscr{F})_{\bar{y}} = \varinjlim \mathrm{H}^q(V \times_Y X, \mathscr{F}),$$

where the direct limit is taken over the étale neighbourhoods V of $\bar{y}$.

Let $\mathscr{O}_{Y,\bar{y}}$ be the strict localization of Y at $\bar{y}$, let $\widetilde{Y} = \mathrm{Spec}(\mathscr{O}_{Y,\bar{y}})$, and let $\widetilde{X} = X \times_Y \widetilde{Y}$. The sheaf $\mathscr{F}$ may be extended to $\widetilde{X}_{\mathrm{et}}$ (this is a special case of the general notion of inverse image) as follows. Let $\widetilde{U}$ be a scheme étale over $\widetilde{X}$. Then there exist an étale neighbourhood V of $\bar{y}$ and a scheme U étale over $X \times_Y V$ such that $\widetilde{U} = U \times_V \widetilde{Y}$; set

$$\mathscr{F}(\widetilde{U}) = \varinjlim \mathscr{F}\left(U \times_V V'\right),$$

where the direct limit is taken over the étale neighbourhoods V' of $\bar{y}$ that dominate V. With this definition,

$$(\mathsf{R}^q f_* \mathscr{F})_{\bar{y}} = \mathrm{H}^q(\widetilde{X}, \mathscr{F}).$$

The functor f_* has a left adjoint f^*, the "inverse image" functor. If $\bar{x}$ is a geometric point of X and $f(\bar{x})$ its image in Y, then $(f^*\mathscr{F})_{\bar{x}} = \mathscr{F}_{f(\bar{x})}$. This formula shows that f^* is exact. Consequently, f_* sends injective sheaves to injective sheaves, and the spectral sequence for the composite functor $\Gamma \circ f_*$ (resp. $g_* f_*$) gives the following theorem.

Theorem 2.3.4 (Leray spectral sequence)**.** *Let $\mathscr{F}$ be an abelian sheaf on X_{et} and let $f : X \to Y$ be a morphism of schemes (resp. let $X \xrightarrow{f} Y \xrightarrow{g} Z$ be morphisms of schemes). There is a spectral sequence*

$$E_2^{pq} = \mathrm{H}^p(Y, \mathsf{R}^q f_* \mathscr{F}) \Rightarrow \mathrm{H}^{p+q}(X, \mathscr{F})$$

(resp. $E_2^{pq} = \mathsf{R}^p g_* \mathsf{R}^q f_* \mathscr{F} \Rightarrow \mathsf{R}^{p+q}(gf)_* \mathscr{F}$*).*

Corollary 2.3.5. *If $\mathsf{R}^q f_* \mathscr{F} = 0$ for every $q > 0$, then $\mathrm{H}^p(Y, f_* \mathscr{F}) = \mathrm{H}^p(X, \mathscr{F})$ (resp. $\mathsf{R}^p g_*(\mathscr{F}_* \mathscr{F}) = \mathsf{R}^p(gf)_* \mathscr{F}$) for every $p \geqslant 0$.*

This applies in particular in the following case:

Proposition 2.3.6. *Let $f : X \to Y$ be a finite morphism (or even, by passage to the limit, an integral morphism), and let $\mathscr{F}$ be an abelian sheaf on X. Then $\mathsf{R}^q f_* \mathscr{F} = 0$ for every $q > 0$.*

Indeed, let $\bar{y}$ be a geometric point of Y, let $\widetilde{Y}$ be the spectrum of the strict localization of Y at y, and let $\widetilde{X} = X \times_Y \widetilde{Y}$. By the preceding discussion, it suffices to prove that $\mathrm{H}^q(\widetilde{X}, \mathscr{F}) = 0$ for every $q > 0$. But $\widetilde{X}$ is the spectrum of a product of strictly henselian local rings (cf. [30, I]), and the functor $\Gamma(\widetilde{X}, -)$ is exact because every surjective étale $\widetilde{X}$-scheme admits a section. This proves the assertion.

2.4 Galois cohomology

For $X = \mathrm{Spec}(K)$, the spectrum of a field, we shall see that étale cohomology can be identified with Galois cohomology.

2.4.1

We begin with a topological analogy. If K is the function field of an integral affine algebraic variety $Y = \mathrm{Spec}(A)$ over $\mathbb{C}$, then $K = \varinjlim_{f \in A} A[1/f]$.

In other words, $X = \varprojlim U$, where U runs over the open subsets of Y. It is known that there exist arbitrarily small Zariski open subsets that are $K(\pi, 1)$ spaces for the classical topology. It is therefore natural to regard $\mathrm{Spec}(K)$ itself as a $K(\pi, 1)$, where π is the fundamental group (in the algebraic sense) of X, namely the Galois group of $\bar{K}/K$, where $\bar{K}$ is a separable closure of K.

2.4.2

More precisely, let K be a field, let $\bar{K}$ be a separable closure of K, and let $G = \mathrm{Gal}(\bar{K}/K)$ be the topological Galois group. To every finite étale K-algebra A (a finite product of separable extensions of K), associate the finite set $\hom_K(A, \bar{K})$. The Galois group G acts on this set through a discrete (hence finite) quotient. If $A = K[T]/(F)$, this set is identified with the set of roots of F in $\bar{K}$. Galois theory, in the form given to it by Grothendieck, says:

Proposition 2.4.3. *The functor*

$$\left\{ \begin{array}{c} K\text{-algebras} \\ \text{finite étale} \end{array} \right\} \to \left\{ \begin{array}{c} \text{finite sets on which} \\ G \text{ acts continuously} \end{array} \right\}$$

that associates $\hom_K(A, \bar{K})$ *to an étale algebra A is an anti-equivalence of categories.*

This yields an analogous description of sheaves for the étale topology on $\mathrm{Spec}(K)$:

Proposition 2.4.4. *The functor*

$$\left\{ \begin{array}{c} \text{étale sheaves} \\ \text{on } \mathrm{Spec}(K) \end{array} \right\} \to \left\{ \begin{array}{c} \text{sets on which} \\ G \text{ acts continuously} \end{array} \right\}$$

that associates to a sheaf $\mathscr{F}$ its fibre $\mathscr{F}_{\bar{K}}$ at the geometric point $\mathrm{Spec}(\bar{K})$ *is an equivalence of categories.*

The group G is said to act continuously on a set E if the stabilizer of every element of E is an open subgroup of G. The inverse functor is described in the evident way: let A be a finite étale K-algebra, let $U = \mathrm{Spec}(A)$, and let $U(\bar{K}) = \hom_K(A, \bar{K})$ be the corresponding G-set; then $\mathscr{F}(U) = \hom_{G\text{-set}}(U(\bar{K}), \mathscr{F}_{\bar{K}})$.

In particular, if $X = \mathrm{Spec}(K)$, then $\mathscr{F}(X) = \mathscr{F}_{\bar{K}}^G$. Restricting to abelian sheaves and passing to derived functors gives canonical isomorphisms

$$\mathrm{H}^q(X_{\mathrm{et}}, \mathscr{F}) = \mathrm{H}^q(G, \mathscr{F}_{\bar{K}})$$

2.4.5 Examples

a) The constant sheaf $\mathbb{Z}/n$ corresponds to $\mathbb{Z}/n$ with the trivial action of G.

b) The sheaf $\boldsymbol{\mu}_n$ of nth roots of unity corresponds to the group $\boldsymbol{\mu}_n(\bar{K})$ of nth roots of unity in $\bar{K}$, with the natural action of G.

c) The sheaf $\mathbb{G}_m$ corresponds to the group $\bar{K}^\times$ with the natural action of G.

3 The cohomology of curves

For topological spaces, unwindings using the Künneth formula and simplicial decompositions reduce the calculation of cohomology to the interval $I = [0, 1]$, for which $\mathrm{H}^0(I, \mathbb{Z}) = \mathbb{Z}$ and $\mathrm{H}^q(I, \mathbb{Z}) = 0$ for $q > 0$.

In our case, the unwindings lead to more complicated objects, namely curves over an algebraically closed field; in this chapter we calculate their cohomology. The situation is more complicated than in the topological case, because the cohomology groups vanish only for $q > 2$. The essential ingredient in the calculations is the vanishing of the Brauer group of the function field of such a curve (Tsen's theorem, 3.2).

3.1 The Brauer group

We first recall its classical definition.

Definition 3.1.1. *Let K be a field and let A be a finite-dimensional K-algebra. The algebra A is called a central simple algebra over K if the following equivalent conditions hold:*

a) A has no nontrivial two-sided ideal, and its centre is K.

b) There exists a finite Galois extension K'/K such that $A_{K'} = A \otimes_K K'$ is isomorphic to an algebra of square matrices over K'.

c) A is K-isomorphic to an algebra of square matrices over a division algebra with centre K.

Two such algebras are called equivalent if the division algebras associated with them by c) are K-isomorphic. If the algebras have the same dimension, this is equivalent to their being K-isomorphic. Tensor product induces, on passing to the quotient, an abelian group structure on the set of equivalence classes. This group is classically called the *Brauer group* of K and is denoted by $\mathrm{Br}(K)$.

3.1.2

We denote by $\mathrm{Br}(n, K)$ the set of K-isomorphism classes of K-algebras A such that there exists a finite Galois extension K' of K for which $A_{K'}$ is isomorphic to the algebra $M_n(K')$ of $n \times n$ square matrices over K'. By definition, $\mathrm{Br}(K)$ is the union of the subsets $\mathrm{Br}(n, K)$ for $n \in \mathbb{N}$. Let $\bar{K}$ be an algebraic closure of K and let $G = \mathrm{Gal}(\bar{K}/K)$. The set $\mathrm{Br}(n, K)$ is the set of "forms" of $M_n(\bar{K})$, and hence is canonically isomorphic to $\mathrm{H}^1\left(G, \mathrm{Aut}(M_n(\bar{K}))\right)$.

Every automorphism of $M_n(\bar{K})$ is inner. Consequently, $\mathrm{Aut}(M_n(\bar{K}))$ is identified with the projective linear group $\mathrm{PGL}(n, \bar{K})$, and there is a canonical bijection

$$\theta_n : \mathrm{Br}(n, K) \xrightarrow{\sim} \mathrm{H}^1\left(G, \mathrm{PGL}(n, \bar{K})\right).$$

On the other hand, the exact sequence

$$1 \to \bar{K}^\times \to \mathrm{GL}(n, \bar{K}) \to \mathrm{PGL}(n, \bar{K}) \to 1, \tag{3.1.2.1}$$

defines a coboundary operator

$$\Delta_n : \mathrm{H}^1\left(G, \mathrm{PGL}(n, \bar{K})\right) \to \mathrm{H}^2(G, \bar{K}^\times).$$

Composing θ_n and Δ_n gives a map

$$\delta_n : \mathrm{Br}(n, K) \to \mathrm{H}^2(G, \bar{K}^\times).$$

It is readily checked that the maps δ_n are compatible and define a group homomorphism

$$\delta : \mathrm{Br}(K) \to \mathrm{H}^2(G, \bar{K}^\times).$$

Proposition 3.1.3. *The homomorphism $\delta : \mathrm{Br}(K) \to \mathrm{H}^2(G, \bar{K}^\times)$ is bijective.*

This follows from the next two lemmas.

Lemma 3.1.4. *The map $\Delta_n : \mathrm{H}^1\left(G, \mathrm{PGL}(n, \bar{K})\right) \to \mathrm{H}^2(G, \bar{K}^\times)$ is injective.*

By [36], Corollary to Proposition I-44, it suffices to check that whenever the exact sequence (3.1.2.1) is twisted by an element of $\mathrm{H}^1\left(G, \mathrm{PGL}(n, \bar{K})\right)$, the H^1 of the middle group is trivial. This middle group is the group of $\bar{K}$-points of the multiplicative group of a central simple algebra A of rank n^2 over K. To prove that $\mathrm{H}^1(G, A_{\bar{K}}^{\times}) = 0$, interpret $A^{\times}$ as the automorphism group of the free A-module L of rank 1, and H^1 as the set of "forms" of L—A-modules of rank n^2 over K, which are automatically free.

Lemma 3.1.5. *Let $\alpha \in \mathrm{H}^2(G, \bar{K}^{\times})$, let K' be a finite extension of K contained in $\bar{K}$, let $n = [K' : K]$, and let $G' = \mathrm{Gal}(\bar{K}/K')$. If the image of α in $\mathrm{H}^2(G', \bar{K}^{\times})$ is zero, then α belongs to the image of Δ_n.*

First note that

$$\mathrm{H}^2(G', \bar{K}^{\times}) \simeq \mathrm{H}^2\left(G, (\bar{K} \otimes_K K')^{\times}\right).$$

(Geometrically, if $x = \mathrm{Spec}(K)$, $x' = \mathrm{Spec}(K')$, and $\pi : x' \to x$ is the canonical morphism, then $\mathsf{R}^q\pi_*(\mathbb{G}_{m,x'}) = 0$ for $q > 0$ and consequently $\mathrm{H}^q(x', \mathbb{G}_{m,X'}) \simeq \mathrm{H}^q(x, \pi_*\mathbb{G}_{m,X'})$ for $q \geqslant 0$.)

Moreover, the choice of a basis of K' as a vector space over K defines a homomorphism

$$(\bar{K} \otimes_K K')^{\times} \to \mathrm{GL}(n, \bar{K})$$

that sends an element x to the endomorphism of $\bar{K} \otimes_K K'$ given by multiplication by x. There is then a commutative diagram with exact rows:

$$\begin{array}{ccccccccc}
1 & \longrightarrow & \bar{K}^{\times} & \longrightarrow & (\bar{K} \otimes_K K')^{\times} & \longrightarrow & (\bar{K} \otimes_K K')^{\times}/\bar{K}^{\times} & \longrightarrow & 1 \\
 & & \| & & \downarrow & & \downarrow & & \\
1 & \longrightarrow & \bar{K}^{\times} & \longrightarrow & \mathrm{GL}(n, \bar{K}) & \longrightarrow & \mathrm{PGL}(n, \bar{K}) & \longrightarrow & 1
\end{array}$$

The lemma follows from the commutative diagram obtained by passing to cohomology:

$$\begin{array}{ccccc}
\mathrm{H}^1\left(G, (\bar{K} \otimes_K K')^{\times}/\bar{K}^{\times}\right) & \longrightarrow & \mathrm{H}^2(G, \bar{K}^{\times}) & \longrightarrow & \mathrm{H}^2\left(G, (\bar{K} \otimes_K K')^{\times}\right) \\
\downarrow & & \| & & \\
\mathrm{H}^1\left(G, \mathrm{PGL}(n, \bar{K})\right) & \xrightarrow{\Delta_n} & \mathrm{H}^2(G, \bar{K}^{\times}). & &
\end{array}$$

Proposition 3.1.6. *Let K be a field, let $\bar{K}$ be an algebraic closure of K, and let $G = \mathrm{Gal}(\bar{K}/K)$. Suppose that $\mathrm{Br}(K') = 0$ for every finite extension K' of K. Then:*

i) $\mathrm{H}^q(G, \bar{K}^{\times}) = 0$ *for every* $q > 0$.

ii) $\mathrm{H}^q(G, \mathscr{F}) = 0$ *for every torsion G-module $\mathscr{F}$ and every $q \geqslant 2$.*

(For the proof, cf. [36].)

3.2 Tsen's theorem

Definition 3.2.1. *A field K is called C_1 if every nonconstant homogeneous polynomial $f(x_1, \ldots, x_n)$ of degree $d < n$ has a nontrivial zero.*

Proposition 3.2.2. *If a field K is C_1, then $\mathrm{Br}(K) = 0$.*

We must show that every division algebra D with centre K and finite over K is equal to K. Let r^2 be the degree of D over K and let $\mathrm{Nrd} : D \to K$ be the reduced norm.

(Locally for the étale topology on K, D is isomorphic—not canonically—to a matrix algebra M_r, and the reduced norm agrees with the determinant map. This is well defined independently of the chosen isomorphism between D and M_r, because every automorphism of M_r is inner and similar matrices have the same determinant. This map, defined locally for the étale topology, descends, by its local uniqueness, to a map $\mathrm{Nrd} : D \to K$.)

The only zero of Nrd is the zero element of D, since for $x \neq 0$ one has $\mathrm{Nrd}(x) \cdot \mathrm{Nrd}(x^{-1}) = 1$. On the other hand, if $\{e_1, \ldots, e_{r^2}\}$ is a basis of D over K and $x = \sum x_i e_i$, then $\mathrm{Nrd}(x)$ is a homogeneous polynomial $\mathrm{Nrd}(x_1, \ldots, x_{r^2})$ of degree r (this is clear locally for the étale topology). Since K is C_1, one has $r^2 \leqslant r$, that is, $r = 1$ and $D = K$.

Theorem 3.2.3 (Tsen)**.** *Let k be an algebraically closed field and let K be an extension of k of transcendence degree 1. Then K is C_1.*

First suppose that $K = k(X)$. Let

$$f(T) = \sum a_{i_1,\ldots i_n} T_1^{i_1} \cdots T_n^{i_n}$$

be a homogeneous polynomial of degree $d < n$ with coefficients in $k(X)$. After multiplying the coefficients by a common denominator, we may suppose that they lie in $k[X]$. Let $\delta = \sup \deg(a_{i_1 \ldots i_n})$. We seek a nontrivial zero in $k[X]$ by the method of undetermined coefficients, writing each T_i $(i = 1, \ldots, n)$ as a polynomial of degree N in X. The equation $f(T) = 0$ then becomes a system of homogeneous equations in the $n \times (N+1)$ coefficients of the polynomials $T_i(X)$, expressing the vanishing of the coefficients of the polynomial in X obtained by replacing T_i with $T_i(X)$. This polynomial has degree at most $\delta + ND$, so there are $\delta + Nd + 1$ equations in $n \times (N+1)$ variables. Since k is algebraically closed, this system has a nontrivial solution if $n(N+1) > Nd + \delta + 1$, which holds for sufficiently large N when $d < n$.

To prove the theorem in general, it plainly suffices to prove it when K is a finite extension of the purely transcendental extension $k(X)$ of k. Let $f(T) = f(T_1, \ldots, T_n)$ be a homogeneous polynomial of degree $d < n$ with coefficients in K. Let $a = [K : k(X)]$ and let $e_1, \ldots, e_s$ be a basis of K over $k(X)$. Introduce sn new variables U_{ij} such that $T_i = \sum U_{ij} e_j$. For $f(T)$ to have a nontrivial zero in K, it suffices that the polynomial $g(X_{ij}) = N_{K/k}(f(T))$ have a nontrivial zero in $k(X)$. But g is a polynomial of degree sd in sn variables, which proves the result.

Corollary 3.2.4. *Let k be an algebraically closed field and let K be an extension of k of transcendence degree 1. Then the étale cohomology groups $\mathrm{H}^q(\mathrm{Spec}(K), \mathbb{G}_m)$ vanish for every $q > 0$.*

3.3 Cohomology of smooth curves

From now on, unless expressly stated otherwise, all cohomology groups are étale cohomology groups.

Proposition 3.3.1. *Let k be an algebraically closed field and let X be a connected nonsingular projective curve over k. Then*

$$\begin{aligned} \mathrm{H}^0(X, \mathbb{G}_m) &= k^\times, \\ \mathrm{H}^1(X, \mathbb{G}_m) &= \mathrm{Pic}(X), \\ \mathrm{H}^q(X, \mathbb{G}_m) &= 0 \text{ for } q \geqslant 2. \end{aligned}$$

Let η be the generic point of X, let $j : \eta \to X$ be the canonical morphism, and let $\mathbb{G}_{m,X}$ be the multiplicative group of the function field $K(X)$. For every closed point x of X, let $i_x : x \to X$ be the

canonical immersion and let $\mathbb{Z}_x$ be the constant sheaf with value $\mathbb{Z}$ on x. Thus $j_*\mathbb{G}_{m,\eta}$ is the sheaf of nonzero meromorphic functions on X and $\oplus_{x\in X} i_{x_I}\mathbb{Z}_x$ is the sheaf of divisors; hence there is an exact sequence of sheaves:

$$0 \longrightarrow \mathbb{G}_m \longrightarrow j_*\mathbb{G}_{m,\eta} \xrightarrow{\text{div}} \bigoplus_{x\in X} i_{x*}\mathbb{Z}_x \longrightarrow 0. \tag{3.3.1.1}$$

Lemma 3.3.2. *One has* $\mathsf{R}^q j_*\mathbb{G}_{m,\eta} = 0$ *for every* $q > 0$.

It suffices to show that the fibre of this sheaf at every closed point x of X is zero. If $\tilde{\mathscr{O}}_{X,x}$ is the henselization of X at x and K is the fraction field of $\tilde{\mathscr{O}}_{X,x}$, then

$$\mathrm{Spec}(K) = \eta \times_X \mathrm{Spec}(\tilde{\mathscr{O}}_{X,x}),$$

and hence $(\mathsf{R}^q j_*\mathbb{G}_{m,\eta})_x = \mathrm{H}^q(\mathrm{Spec}(K), \mathbb{G}_m)$.

Now K is an algebraic extension of $k(X)$, hence an extension of k of transcendence degree 1; the lemma follows from (3.2.4).

Lemma 3.3.3. *One has* $\mathrm{H}^q(X, j_*\mathbb{G}_{m,\eta}) = 0$ *for every* $q > 0$.

Indeed, (3.3.2) and the Leray spectral sequence for j give

$$\mathrm{H}^q(X, j_*\mathbb{G}_{m,\eta}) = \mathrm{H}^q(\eta, \mathbb{G}_{m,\eta})$$

for every $q \geqslant 0$, and the right-hand side vanishes for $q > 0$ by (3.2.4).

Lemma 3.3.4. *One has* $\mathrm{H}^q\left(X, \bigoplus_{x\in X} i_{x*}\mathbb{Z}_x\right) = 0$ *for every* $q > 0$.

Indeed, for every closed point of X one has $\mathsf{R}^q i_{x*}\mathbb{Z}_x 0$ for $q > 0$, because i_x is a finite morphism (2.3.6), and

$$\mathrm{H}^q(X, i_{x*}\mathbb{Z}_x) = \mathrm{H}^q(x, \mathbb{Z}_x).$$

The right-hand side vanishes for every $q > 0$ because x is the spectrum of an algebraically closed field. (This also shows that the lemma holds more generally for every skyscraper sheaf on X.)

The preceding lemmas and the exact sequence (3.3.1.1) give

$$\mathrm{H}^q(X, \mathbb{G}_m) = 0 \text{ for } q \geqslant 2,$$

and the low-degree exact cohomology sequence

$$1 \to \mathrm{H}^0(X, \mathbb{G}_m) \to \mathrm{H}^0(X, j_*\mathbb{G}_{m,\eta}) \to \mathrm{H}^0\left(X, \bigoplus_{x\in X} i_{x*}\mathbb{Z}_x\right) \to \mathrm{H}^1(X, \mathbb{G}_m) \to 1$$

which is precisely the exact sequence

$$1 \to k^\times \to k(X)^\times \to \mathrm{Div}(X) \to \mathrm{Pic}(X) \to 1.$$

Proposition 3.3.1 implies that the cohomology groups of X with values in $\mathbb{Z}/n$, for n prime to the characteristic of k, have reasonable values:

Corollary 3.3.5. *If X has genus g and n is invertible in k, then $\mathrm{H}^q(X, \mathbb{Z}/n)$ vanishes for $q > 2$ and is free over $\mathbb{Z}/n$ of ranks $1, 2g, 1$ for $q = 0, 1, 2$. Replacing $\mathbb{Z}/n$ by the isomorphic group $\boldsymbol{\mu}_n$, there are canonical isomorphisms*

$$\mathrm{H}^0(X, \boldsymbol{\mu}_n) = \boldsymbol{\mu}_n$$
$$\mathrm{H}^1(X, \boldsymbol{\mu}_n) = \mathrm{Pic}^0(X)_n$$
$$\mathrm{H}^2(X, \boldsymbol{\mu}_n) = \mathbb{Z}/n.$$

Since k is algebraically closed, $\mathbb{Z}/n$ is isomorphic (noncanonically) to μ_n. The Kummer exact sequence

$$0 \to \mu_n \to \mathbb{G}_m \to \mathbb{G}_m \to 0,$$

and Proposition 3.3.1 yield the equalities

$$\mathrm{H}^q(X, \mathbb{Z}/n) = 0 \text{ for } q > 2,$$

and, in low degrees, the exact sequences

$$0 \longrightarrow \mathrm{H}^0(X, \boldsymbol{\mu}_n) \longrightarrow k^\times \xrightarrow{n} k^\times \longrightarrow 0$$

$$0 \longrightarrow \mathrm{H}^1(X, \boldsymbol{\mu}_n) \longrightarrow \mathrm{Pic}(X) \xrightarrow{n} \mathrm{H}^2(X, \boldsymbol{\mu}_n) \longrightarrow 0.$$

Moreover, there is an exact sequence

$$0 \longrightarrow \mathrm{Pic}^0(X) \longrightarrow \mathrm{Pic}(X) \xrightarrow{\deg} \mathbb{Z} \longrightarrow 0,$$

and $\mathrm{Pic}^0(X)$ is identified with the group of k-rational points of an abelian variety of dimension g, the Jacobian of X. In such a group, multiplication by n is surjective and its kernel is a free $\mathbb{Z}/n\mathbb{Z}$-module of rank $2g$ (because n is invertible in k); this proves the corollary.

A clever unwinding using the "trace method" yields the following proposition as a corollary.

Proposition 3.3.6 ([2, IX 5.7])**.** *Let k be an algebraically closed field, let X be an algebraic curve over k, and let $\mathscr{F}$ be a torsion sheaf on X. Then:*

i) $\mathrm{H}^q(X, \mathscr{F}) = 0$ *for* $q > 2$.

ii) If X is affine, then even $\mathrm{H}^q(X, \mathscr{F}) = 0$ *for* $q > 1$.

For the proof, as well as for an exposition of the "trace method," we refer to [2, IX 5].

3.4 Unwindings

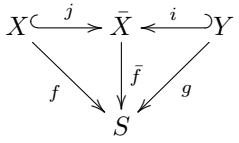
To calculate the cohomology of varieties of dimension > 1, one uses fibrations by curves, thereby reducing to the study of morphisms whose fibres have dimension $\leqslant 1$. This principle has several variants; we mention some of them.

3.4.1

Let A be a k-algebra of finite type, and let $a_1, \ldots, a_n$ be generators of A. If we put $X_0 = \mathrm{Spec}(k)$, $X_i = \mathrm{Spec}(k[a_1, \ldots, a_i])$, and $X_n = \mathrm{Spec}(A)$, the canonical inclusions $k[a_1, \ldots, a_i] \to k[a_1, \ldots, a_i, a_{i+1}]$ define morphisms $X_n \to X_{n-1} \to \cdots \to X_1 \to X_0$ whose fibres have dimension $\leqslant 1$.

3.4.2

For a smooth morphism, one can be more precise. An *elementary fibration* is a morphism of schemes $f : X \to S$ that can be embedded in a commutative diagram



satisfying the following conditions:

i) j is an open immersion, dense in every fibre, and $X = \bar{X} \smallsetminus Y$.

ii) $\bar{f}$ is smooth and projective, with irreducible geometric fibres of dimension 1.

iii) g is an étale covering and no fibre of g is empty.

A *good neighbourhood* relative to S is an S-scheme X for which there exist S-schemes $X = X_n, \ldots, X_0 = S$ and elementary fibrations $f_i : X_i \to X_{i-1}$, $i = 1, \ldots, n$. One can show [2, XI 3.3] that if X is a smooth scheme over an algebraically closed field k, then every rational point of X has an open neighbourhood that is a good neighbourhood (relative to $\mathrm{Spec}(K)$).

3.4.3

A proper morphism $f : X \to S$ can be unwound as follows. By Chow's lemma, there is a commutative diagram

$$\begin{array}{ccc} X & \xleftarrow{\pi} & \bar{X} \\ & \searrow^{f} & \downarrow{\scriptstyle \bar{f}} \\ & & S \end{array}$$

in which π and $\bar{f}$ are projective morphisms, with π in addition an isomorphism over a dense open subset of X. Locally on S, $\bar{X}$ is a closed subscheme of a standard projective space $\mathbb{P}^n_S$.

The latter is unwound by considering the projection $\varphi : \mathbb{P}^n_S \to \mathbb{P}^1_S$ that sends the point with homogeneous coordinates $(x_0, x_1, \ldots, x_n)$ to (x_0, x_1). This is a rational map defined outside the closed subset $Y \simeq \mathbb{P}^{n-2}_S$ of $\mathbb{P}^n_S$ given by the homogeneous equations $x_0 = x_1 = 0$. Let $u : P \to \mathbb{P}^n_S$ be the blow-up with centre Y; the fibres of u have dimension $\leqslant 1$. Moreover, there is a natural morphism $v : P \to \mathbb{P}^1_S$ extending the rational map φ, and v makes P a $\mathbb{P}^1_S$-scheme locally isomorphic to the standard projective space $\mathbb{P}^{n-1}$, which may in turn be projected onto a $\mathbb{P}^1$, and so on.

3.4.4

A smooth projective variety X can be swept out by a *Lefschetz pencil*. The blow-up $\widetilde{X}$ of the intersection of the axis of the pencil with X maps to $\mathbb{P}^1$, and the fibres of this map are the hyperplane sections of X by the hyperplanes of the pencil.

4 The proper base change theorem

4.1 Introduction

This chapter is devoted to the proof and applications of the following theorem.

Theorem 4.1.1. *Let $f : X \to S$ be a proper morphism of schemes and let $\mathscr{F}$ be a torsion abelian sheaf on X. Then, for every $q \geqslant 0$, the fibre of $\mathrm{R}^q f_* \mathscr{F}$ at a geometric point s of S is isomorphic to the cohomology $\mathrm{H}^q(X_s, \mathscr{F})$ of the fibre $X_s = X \otimes_S \mathrm{Spec}\, k(s)$ of f at s.*

For a proper separated continuous map $f : X \to S$ between topological spaces (separated means that the diagonal of $X \times_S X$ is closed) and an abelian sheaf $\mathscr{F}$ on X, the analogous result is well known and elementary. Since f is closed, the $f^{-1}(V)$, with V ranging over the neighbourhoods of s, form a fundamental system of neighbourhoods of X_s, and one checks that $\mathrm{H}^\bullet(X_s, \mathscr{F}) = \varinjlim_U \mathrm{H}^\bullet(U, \mathscr{F})$, where U ranges over the neighbourhoods of X_s. In practice, X_s even has a fundamental system $\mathcal{U}$ of neighbourhoods

U of which it is a deformation retract, and for $\mathscr{F}$ constant one therefore has $\mathrm{H}^\bullet(X_s, \mathscr{F}) = \mathrm{H}^\bullet(U, \mathscr{F})$. Figuratively speaking, the special fibre swallows the general fibre.

For schemes the proof is more delicate, and it is essential to suppose that $\mathscr{F}$ is torsion ([2, XII.2]). In view of the description of the fibres of $\mathsf{R}^q f_* \mathscr{F}$ (2.3.3), Theorem (4.1.1) is essentially equivalent to the following theorem.

Theorem 4.1.2. *Let A be a strictly henselian local ring and let $S = \mathrm{Spec}(A)$. Let $f : X \to S$ be proper, and let X_0 be the closed fibre of f. Then, for every torsion abelian sheaf $\mathscr{F}$ on X and every $q \geqslant 0$, one has $\mathrm{H}^q(X, \mathscr{F}) \xrightarrow{\sim} \mathrm{H}^q(X_0, \mathscr{F})$.*

By passage to the limit, it suffices to prove the theorem when A is the strict henselization of a finitely generated $\mathbb{Z}$-algebra at a prime ideal. We first treat the case $q = 0$ or 1 and $\mathscr{F} = \mathbb{Z}/n$ (4.2). An argument based on constructible sheaves (4.3) shows moreover that it suffices to consider constant $\mathscr{F}$. On the other hand, the unwinding in (3.4.3) allows us to suppose that X_0 is a curve; in that case it remains only to prove the theorem for $q = 2$ (4.4).

Among other applications (4.6), the theorem allows one to define cohomology with proper support (4.5).

4.2 Proof for $q = 0$ or 1 and $\mathscr{F} = \mathbb{Z}/n$

The result for $q = 0$ and $\mathscr{F}$ constant is equivalent to the following proposition (Zariski's connectedness theorem).

Proposition 4.2.1. *Let A be a noetherian henselian local ring and let $S = \mathrm{Spec}(A)$. Let $f : X \to S$ be a proper morphism, and let X_0 be the closed fibre of f. Then the sets of connected components $\pi_0(X)$ and $\pi_0(X_0)$ are in bijection.*

Equivalently, we must show that the sets $\mathrm{Of}(X)$ and $\mathrm{Of}(X_0)$ of open-and-closed subsets are in bijection. The set $\mathrm{Of}(X)$ is known to correspond bijectively to the set of idempotents of $\Gamma(X, \mathscr{O}_X)$, and similarly $\mathrm{Of}(X_0)$ corresponds bijectively to the set of idempotents of $\Gamma(X_0, \mathscr{O}_{X_0})$. Thus we must show that the canonical map

$$\mathrm{Idem}\,\Gamma(X, \mathscr{O}_X) \to \mathrm{Idem}\,\Gamma(X_0, \mathscr{O}_{X_0})$$

is bijective.

Let $\mathfrak{m}$ denote the maximal ideal of A, let $\Gamma(X, \mathscr{O}_X)^\wedge$ denote the completion of $\Gamma(X, \mathscr{O}_X)$ for the $\mathfrak{m}$-adic topology, and, for every integer $n \geqslant 0$, let $X_n = X \otimes_A A/\mathfrak{m}^{n+1}$. By the finiteness theorem for proper morphisms [20, III.3.2], $\Gamma(X, \mathscr{O}_X)$ is a finite A-algebra; since A is henselian, the canonical map

$$\mathrm{Idem}\,\Gamma(X, \mathscr{O}_X) \to \mathrm{Idem}\,\Gamma(X, \mathscr{O}_X)^\wedge$$

is bijective. In particular, the canonical map

$$\mathrm{Idem}\,\Gamma(X, \mathscr{O}_X)^\wedge \to \varprojlim \mathrm{Idem}\,\Gamma(X_n, \mathscr{O}_{X_n})$$

is bijective. But since X_n and X_0 have the same underlying topological space, the canonical map

$$\mathrm{Idem}\,\Gamma(X_n, \mathscr{O}_{X_n}) \to \mathrm{Idem}\,\Gamma(X_0, \mathscr{O}_{X_0})$$

is bijective for every n, which completes the proof.

Since $\mathrm{H}^1(X, \mathbb{Z}/n)$ is in bijection with the set of isomorphism classes of Galois étale coverings of X with group $\mathbb{Z}/n$, the theorem for $q = 1$ and $\mathscr{F} = \mathbb{Z}/n$ follows from the next proposition.

Proposition 4.2.2. *Let A be a noetherian henselian local ring and let $S = \mathrm{Spec}(A)$. Let $f : X \to S$ be a proper morphism, and let X_0 be the closed fibre of f. Then the restriction functor*

$$\mathrm{Rev.\,et}(X) \to \mathrm{Rev.\,et}(X_0)$$

is an equivalence of categories.

(If X_0 is connected and a geometric point of X_0 has been chosen as base point, this says that the canonical map $\pi_1(X_0) \to \pi_1(X)$ on (profinite) fundamental groups is bijective.)

Proposition (4.2.1) shows that this functor is fully faithful. Indeed, if X' and X'' are two étale coverings of X, an X-morphism from X' to X'' is determined by its graph, which is an open-and-closed subset of $X' \times_X X''$.

It remains to show that every étale covering X'_0 of X_0 extends to an étale covering of X. Étale coverings are insensitive to nilpotent elements [23, ch.1]; consequently, X'_0 lifts uniquely to an étale covering X'_n of X_n for every $n \geqslant 0$, in other words, to an étale covering $\mathfrak{X}'$ of the formal scheme $\mathfrak{X}$ obtained by completing X along X_0. By Grothendieck's algebraization theorem for formal coherent sheaves (the existence theorem, [20, III.5]), $\mathfrak{X}'$ is the formal completion of an étale covering $\bar{X}'$ of $\bar{X} = X \otimes_A \hat{A}$.

By passage to the limit, it suffices to prove the proposition when A is the henselization of a finitely generated $\mathbb{Z}$-algebra. We can then apply Artin's approximation theorem to the functor $\mathscr{F} : (A\text{-algebras}) \to (\text{sets})$ that associates to an A-algebra B the set of isomorphism classes of étale coverings of $X \otimes_A B$. Indeed, this functor is locally of finite presentation: if B_i is a filtered direct system of A-algebras and $B = \varinjlim B_i$, then $\mathscr{F}(B) = \varinjlim \mathscr{F}(B_i)$. By Artin's theorem, given an element $\xi \in \mathscr{F}(\hat{A})$, here the isomorphism class of $\bar{X}'$, there exists $\bar{\xi} \in \mathscr{F}(A)$ having the same image as $\bar{\xi}$ in $\mathscr{F}(A/\mathfrak{m})$. In other words, there exists an étale covering X' of X whose restriction to X_0 is isomorphic to X'_0.

4.3 Constructible sheaves

In this paragraph, X is a *noetherian* scheme, and by a sheaf on X we mean an *abelian* sheaf on X_{et}.

Definition 4.3.1. *A sheaf $\mathscr{F}$ on X is called* locally constant constructible *(abbreviated l.c.c.) if it is represented by an étale covering of X.*

Definition 4.3.2. *A sheaf $\mathscr{F}$ on X is called* constructible *if it satisfies the following equivalent conditions:*

(i) There exists a finite surjective family of subschemes X_i of X such that the restriction of $\mathscr{F}$ to X_i is l.c.c.

(ii) There exist a finite family of finite morphisms $p_i : X'_i \to X$, for each i a constant constructible sheaf C_i (i.e. one defined by a finite abelian group) on X'_i, and a monomorphism $\mathscr{F} \to \prod p_{i*}C_i$.

It is readily checked that the category of constructible sheaves on X is an abelian category. Moreover, if $u : \mathscr{F} \to \mathscr{G}$ is a homomorphism of sheaves and $\mathscr{F}$ is constructible, then $\mathrm{im}(u)$ is constructible.

Lemma 4.3.3. *Every torsion sheaf $\mathscr{F}$ is a filtered direct limit of constructible sheaves.*

Indeed, if $j : U \to X$ is an étale scheme of finite type over X, an element $\xi \in \mathscr{F}(U)$ such that $n\xi = 0$ defines a homomorphism of sheaves $j_!\underline{\mathbb{Z}/n} \to \mathscr{F}$ whose image (the smallest subsheaf of $\mathscr{F}$ for which ξ is a local section) is a constructible subsheaf of $\mathscr{F}$. Clearly $\mathscr{F}$ is the direct limit of such subsheaves.

Definition 4.3.4. *Let $\mathcal{C}$ be an abelian category and let T be a functor from $\mathcal{C}$ to the category of abelian groups. The functor T is called* effaceable *in $\mathcal{C}$ if, for every object A of $\mathcal{C}$ and every $\alpha \in T(A)$, there exists a monomorphism $u : A \to M$ in $\mathcal{C}$ such that $T(u)\alpha = 0$.*

Lemma 4.3.5. *The functors* $\mathrm{H}^q(X,-)$ *for* $q>0$ *are effaceable in the category of constructible sheaves on* X.

It suffices to observe that, if $\mathscr{F}$ is a constructible sheaf, there is necessarily an integer $n>0$ such that $\mathscr{F}$ is a sheaf of $\mathbb{Z}/n$-modules. There is then a monomorphism $\mathscr{F}\hookrightarrow\mathscr{G}$, where $\mathscr{G}$ is a sheaf of $\mathbb{Z}/n$-modules and $\mathrm{H}^q(X,\mathscr{G})=0$ for every $q>0$. For example, one can take for $\mathscr{G}$ the Godement resolution $\prod_{x\in X} i_{x*}\mathscr{F}_{\bar{x}}$, where x runs over the points of X and $i_x:\bar{x}\to X$ is a geometric point centred at X. By (4.3.3), $\mathscr{G}$ is a direct limit of constructible sheaves, whence the lemma, because the functors $\mathrm{H}^q(X,-)$ commute with direct limits.

Lemma 4.3.6. *Let* $\varphi^\bullet: T^\bullet\to T'^\bullet$ *be a morphism of cohomological functors defined on an abelian category* $\mathcal{C}$ *with values in the category of abelian groups. Suppose that* T^q *is effaceable for* $q>0$, *and let* $\mathcal{E}$ *be a subset of the objects of* $\mathcal{C}$ *such that every object of* $\mathcal{C}$ *is contained in an object belonging to* $\mathcal{E}$. *Then the following conditions are equivalent:*

(i) $\varphi^q(A)$ *is bijective for every* $q\geqslant 0$ *and every* $A\in\mathrm{Ob}\,\mathcal{C}$.

(ii) $\varphi^0(M)$ *is bijective and* $\varphi^q(M)$ *is surjective for every* $q>0$ *and every* $M\in\mathcal{E}$.

(iii) $\varphi^0(A)$ *is bijective for every* $A\in\mathrm{Ob}\,\mathcal{C}$, *and* T'^q *is effaceable for every* $q>0$.

The proof is by induction on q and presents no difficulty.

Proposition 4.3.7. *Let* X_0 *be a subscheme of* X. *Suppose that, for every* $n\geqslant 0$ *and every scheme* X' *finite over* X, *the canonical map*

$$\mathrm{H}^q(X',\mathbb{Z}/n)\to\mathrm{H}^q(X'_0,\mathbb{Z}/n),$$

where $X'_0=X'\times_X X_0$, *is bijective for* $q=0$ *and surjective for* $q>0$. *Then, for every torsion sheaf* $\mathscr{F}$ *on* X *and every* $q\geqslant 0$, *the canonical map*

$$\mathrm{H}^q(X,\mathscr{F})\to\mathrm{H}^q(X_0,\mathscr{F})$$

is bijective.

By passage to the limit, it suffices to prove the assertion for constructible $\mathscr{F}$. Apply Lemma (4.3.6) with $\mathcal{C}$ the category of constructible sheaves on X, $T^q=\mathrm{H}^q(X,-)$, $T'^q=\mathrm{H}^q(X_0,-)$, and $\mathcal{E}$ the set of constructible sheaves of the form $\prod p_{i*}C_i$, where $p_i:X'_i\to X$ is finite and C_i is a finite constant sheaf on X'_i.

4.4 End of the proof

By the method of fibration by curves (3.4.3), we reduce to proving the theorem in relative dimension $\leqslant 1$. By the preceding paragraph, it suffices to show the following. If S is the spectrum of a strictly henselian noetherian local ring, $f:X\to S$ is a proper morphism whose closed fibre X_0 has dimension $\leqslant 1$, and n is an integer $\geqslant 0$, then the canonical homomorphism

$$\mathrm{H}^q(X,\mathbb{Z}/n)\to\mathrm{H}^q(X_0,\mathbb{Z}/n)$$

is bijective for $q=0$ and surjective for $q>0$.

The cases $q=0$ and 1 were treated above, and $\mathrm{H}^q(X_0,\mathbb{Z}/n)=0$ for $q\geqslant 3$; it therefore suffices to treat $q=2$. We may clearly suppose that n is a power of a prime. If $n=p^r$, where p is the characteristic of the

residue field of S, Artin–Schreier theory shows that $\mathrm{H}^2(X_0, \mathbb{Z}/p^r) = 0$. If $n = \ell^r$, $\ell \neq p$, Kummer theory gives a commutative diagram

$$\begin{array}{ccc} \mathrm{Pic}(X) & \xrightarrow{\alpha} & \mathrm{H}^2(X, \mathbb{Z}/\ell^r) \\ \downarrow & & \downarrow \\ \mathrm{Pic}(X_0) & \xrightarrow{\beta} & \mathrm{H}^2(X_0, \mathbb{Z}/\ell^r) \end{array}$$

in which β is surjective (this was seen in Chapter 3 for a smooth curve over an algebraically closed field, but similar arguments apply to any curve over a separably closed field).

Thus it suffices to prove:

Proposition 4.4.1. *Let S be the spectrum of a henselian noetherian local ring, and let $f : X \to S$ be a proper morphism whose closed fibre X_0 has dimension $\leqslant 1$. Then the canonical restriction map*

$$\mathrm{Pic}(X) \to \mathrm{Pic}(X_0)$$

is surjective. (In fact, it is enough that f be a separated *morphism of finite type.)*

To simplify the proof, we suppose that X is integral, although this is not necessary. Every invertible sheaf on X_0 is associated with a Cartier divisor (because X_0 is a curve, hence quasi-projective), so it suffices to show that the canonical map $\mathrm{Div}(X) \to \mathrm{Div}(X_0)$ is surjective.

Every divisor on X_0 is a linear combination of divisors whose support is concentrated at a single nonisolated closed point of X_0. Let x be such a point, let $t_0 \in \mathscr{O}_{X_0,x}$ be a regular nonunit in $\mathscr{O}_{X_0,x}$, and let D_0 be the divisor concentrated at x with local equation t_0. Let U be an open neighbourhood of x in X on which there is a section $t \in \Gamma(U, \mathscr{O}_U)$ lifting t_0. Let Y be the closed subset of U defined by $t = 0$; after making U sufficiently small, we may suppose that x is the only point of $Y \cap X_0$. Then Y is quasi-finite over S at x. Since S is the spectrum of a henselian local ring, it follows that $Y = Y_1 \amalg Y_2$, where Y_1 is finite over S and Y_2 does not meet X_0. Moreover, since X is separated over S, Y_1 is closed in X.

After replacing U by a smaller open neighbourhood of x, we may suppose that $Y = Y_1$, in other words, that Y is closed in X. We then define a divisor D on X lifting D_0 by setting $D|X \smallsetminus Y = 0$ and $D|U = \mathrm{div}(t)$; this makes sense because t is invertible on $U \smallsetminus Y$.

4.4.2 Remark

When f is proper, one could also give a proof similar to that of Proposition (4.2.2). Indeed, since X_0 is a curve, there is no obstruction to lifting an invertible sheaf on X_0 to the infinitesimal neighbourhoods X_n of X_0, and hence to the formal completion $\mathfrak{X}$ of X along X_0. One then concludes by applying successively Grothendieck's existence theorem and Artin's approximation theorem.

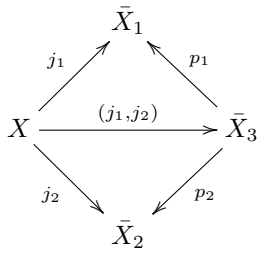
4.5 Cohomology with proper support

Definition 4.5.1. *Let X be a separated scheme of finite type over a field k. By a theorem of Nagata, there exist a scheme $\bar{X}$ proper over k and an open immersion $j : X \to \bar{X}$. For every torsion sheaf $\mathscr{F}$ on X, let $j_!\mathscr{F}$ denote the extension by 0 of $\mathscr{F}$ to $\bar{X}$, and define the groups of* cohomology with proper support *by*

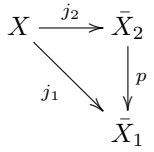
$$\mathrm{H}^q_c(X, \mathscr{F}) = \mathrm{H}^q(\bar{X}, j_!\mathscr{F}).$$

Let us show that this definition is independent of the chosen compactification $j : X \to \bar{X}$. Let $j_1 : X \to \bar{X}_1$ and $j_2 : X \to \bar{X}_2$ be two compactifications. Then X maps into $\bar{X}_1 \times \bar{X}_2$ by $x \mapsto (j_1(x), j_2(x))$,

and the closed image $\bar{X}_3$ of X under this map is a compactification of X. We thus have a commutative diagram



where p_1 and p_2, the restrictions to $\bar{X}_3$ of the natural projections, are proper morphisms. It therefore suffices to treat the case of a commutative diagram



with p proper.

Lemma 4.5.2. *One has $p_*(j_{2!}\mathscr{F}) = j_{1!}\mathscr{F}$ and $\mathsf{R}^q p_*(j_{2!}\mathscr{F}) = 0$ for $q > 0$.*

Let us note at once that the lemma suffices. Using the Leray spectral sequence for p, it gives, for every $q \geqslant 0$,

$$\mathrm{H}^q(\bar{X}_2, j_{2!}\mathscr{F}) = \mathrm{H}^q(\bar{X}_1, j_{1!}\mathscr{F}).$$

To prove the lemma, argue fibre by fibre using the base change theorem (4.1.1) for p. The result is immediate because above a point of X, p is an isomorphism, whereas above a point of $\bar{X}_1 \smallsetminus X$, $j_{2!}\mathscr{F}$ vanishes on the fibre of p.

4.5.3

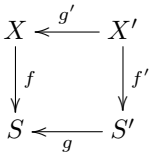
Similarly, if $f : X \to S$ is a separated morphism of finite type between noetherian schemes, there exist a proper morphism $\bar{f} : \bar{X} \to S$ and an open immersion $j : X \to \bar{X}$. The higher direct images with proper support $\mathsf{R}^q f_!$ are defined, for every torsion sheaf $\mathscr{F}$ on X, by

$$\mathsf{R}^q f_!\mathscr{F} = \mathsf{R}^q f_*(j_!\mathscr{F}).$$

As before, one checks that this definition is independent of the chosen compactification.

Theorem 4.5.4. *Let $f : X \to S$ be a separated morphism of finite type between noetherian schemes, and let $\mathscr{F}$ be a torsion sheaf on X. Then the fibre of $\mathsf{R}^q f_!\mathscr{F}$ at a geometric point s of S is isomorphic to the cohomology with proper support $\mathrm{H}^q_c(X_s, \mathscr{F})$ of the fibre X_s of f at s.*

This is a simple variant of the proper base change theorem (4.1.1). More generally, if



is a cartesian diagram, there is a canonical isomorphism

$$g^*(\mathsf{R}^q f_!\mathscr{F}) \simeq \mathsf{R}^q f'_!({g'}^*\mathscr{F}). \tag{4.5.4.1}$$

4.6 Applications

Theorem 4.6.1 (Vanishing theorem)**.** *Let $f : X \to S$ be a separated morphism of finite type whose fibres have dimension $\leqslant n$, and let $\mathscr{F}$ be a torsion sheaf on X. Then $\mathsf{R}^q f_!\mathscr{F} = 0$ for $q > 2n$.*

By the base change theorem, we may suppose that S is the spectrum of a separably closed field. If $\dim X = n$, there exists an affine open U of X such that $\dim(X \smallsetminus U) < n$. We then have an exact sequence $0 \to \mathscr{F}_U \to \mathscr{F} \to \mathscr{F}_{X\smallsetminus U} \to 0$, and induction on n reduces us to proving the theorem for $X = U$ affine. The method of fibration by curves (3.4.1) and the base change theorem then reduce us to a curve over a separably closed field, for which the desired result follows from Tsen's theorem (3.3.6).

Theorem 4.6.2 (Finiteness theorem)**.** *Let $f : X \to S$ be a separated morphism of finite type and let $\mathscr{F}$ be a constructible sheaf on X. Then the sheaves $\mathsf{R}^q f_!\mathscr{F}$ are constructible.*

We consider only the case in which $\mathscr{F}$ is annihilated by an integer invertible on X.

To prove the theorem, one reduces to the case in which $\mathscr{F}$ is the constant sheaf $\underline{\mathbb{Z}/n}$ and $f : X \to S$ is proper and smooth with geometrically connected curve fibres of genus g. If n is invertible on X, the sheaves $\mathsf{R}^q f_*\mathscr{F}$ are then locally free of finite rank and vanish for $q > 2$ (4.6.1). Replacing $\mathbb{Z}/n$ by the sheaf $\boldsymbol{\mu}_n$, which is locally isomorphic to it (over S), there are canonical isomorphisms

$$\begin{aligned} &\mathsf{R}^0 f_*\boldsymbol{\mu}_n = \boldsymbol{\mu}_n \\ &\mathsf{R}^1 f_*\boldsymbol{\mu}_n = \underline{\mathrm{Pic}}(X/S)_n \\ &\mathsf{R}^2 f_*\boldsymbol{\mu}_n = \mathbb{Z}/n. \end{aligned} \tag{4.6.2.1}$$

Theorem 4.6.3 (Comparison with classical cohomology)**.** *Let $f : X \to S$ be a separated morphism of schemes of finite type over $\mathbb{C}$, and let $\mathscr{F}$ be a torsion sheaf on X. Denote by a superscript $(-)^{\mathrm{an}}$ the functor passing to the usual topological spaces, and by $\mathsf{R}^q f_!^{\mathrm{an}}$ the derived functors of direct image with proper support under f^{an}. Then*

$$(\mathsf{R}^q f_!\mathscr{F})^{\mathrm{an}} \simeq \mathsf{R}^q f_!^{\mathrm{an}}\mathscr{F}^{\mathrm{an}}.$$

In particular, when $S =$ a point and $\mathscr{F}$ is the constant sheaf $\mathbb{Z}/n$,

$$\mathrm{H}^q_c(X, \mathbb{Z}/n) \simeq \mathrm{H}^q_c(X^{\mathrm{an}}, \mathbb{Z}/n).$$

Unwindings using the base change theorem reduce us to the case in which X is a smooth proper curve, $S =$ a point, and $\mathscr{F} = \mathbb{Z}/n$. The cohomology groups in question then vanish for $q \neq 0, 1, 2$, and we invoke [32]: indeed, if X is proper over $\mathbb{C}$, then $\pi_0(X) = \pi_0(X^{\mathrm{an}})$ and $\pi_1(X) =$ the profinite completion of $\pi_1(X^{\mathrm{an}})$, which proves the assertion for $q = 0, 1$. For $q = 2$, one uses the Kummer exact sequence and the fact that, again by [32], $\mathrm{Pic}(X) = \mathrm{Pic}(X^{\mathrm{an}})$.

Theorem 4.6.4 (Cohomological dimension of affine schemes)**.** *Let X be an affine scheme of finite type over a separably closed field and let $\mathscr{F}$ be a torsion sheaf on X. Then $\mathrm{H}^1(X, \mathscr{F}) = 0$ for $q > \dim(X)$.*

For the very elegant proof, we refer to [2], XIV §2 and 3.

4.6.5 Remark

This theorem is in a sense a substitute for Morse theory. Indeed, consider the classical case in which X is smooth and affine over $\mathbb{C}$, embedded in a standard affine space $\mathbb{C}^N$. Then, for almost every point $p \in \mathbb{C}^N$, the function "distance from p" on X is a Morse function, and the indices of its critical points are smaller than $\dim(X)$. Thus X is obtained by attaching handles of index less than $\dim(X)$, which gives the classical analogue of (4.6.4).

5 Local acyclicity of smooth morphisms

Let X be a complex analytic variety and let $f : X \to D$ be a morphism from X to the disk. Write $[0,t]$ for the closed line segment in D with endpoints 0 and t, and $(0,t]$ for the half-open segment. If f is *smooth*, the inclusion

$$j : f^{-1}((0,t]) \hookrightarrow f^{-1}([0,t])$$

is a homotopy equivalence; the special fibre $X_0 = f^{-1}(0)$ can be pushed into $f^{-1}([0,t])$.

In practice, for sufficiently small t, $f^{-1}((0,t])$ will be a bundle over $(0,t]$, so that the inclusion

$$X_t = f^{-1}(t) \hookrightarrow f^{-1}((0,t])$$

will also be a homotopy equivalence. The *cospecialization morphism* is then the homotopy class of maps

$$\mathrm{cosp} : X_0 \hookrightarrow f^{-1}([0,t]) \xleftarrow{\sim} f^{-1}((0,t]) \xleftarrow{\sim} X_t.$$

Figuratively speaking, for a smooth morphism the general fibre swallows the special fibre.

No longer suppose that f is necessarily smooth (but suppose that $f^{-1}((0,t])$ is a bundle over $(0,t]$). A morphism $\mathrm{cosp}^\bullet$ can still be defined in cohomology whenever $j_*\mathbb{Z} = \mathbb{Z}$ and $\mathsf{R}^q j_*\mathbb{Z} = 0$ for $q > 0$. Under these hypotheses, the Leray spectral sequence for j shows that

$$\mathrm{H}^\bullet\left(f^{-1}([0,t]), \mathbb{Z}\right) \xrightarrow{\sim} \mathrm{H}^\bullet\left(f^{-1}((0,t]), \mathbb{Z}\right)$$

and $\mathrm{cosp}^\bullet$ is the composite morphism

$$\mathrm{cosp}^\bullet : \mathrm{H}^\bullet(X_t, \mathbb{Z}) \xleftarrow{\sim} \mathrm{H}^\bullet\left(f^{-1}((0,t]), \mathbb{Z}\right) \xleftarrow{\sim} \mathrm{H}^\bullet\left(f^{-1}([0,t]), \mathbb{Z}\right) \to \mathrm{H}^\bullet(X_0, \mathbb{Z})$$

The fibre of $\mathsf{R}^q j_*\mathbb{Z}$ at a point $x \in X_0$ is calculated as follows. In an ambient space, take a ball B_ε centred at x with sufficiently small radius ε, and for sufficiently small η put $E = X \cap B_\varepsilon \cap f^{-1}(\eta t)$; this is the *vanishing-cycle variety* at x. One has

$$(\mathsf{R}^q j_*\mathbb{Z})_x \xleftarrow{\sim} \mathrm{H}^q\left(X \cap B_\varepsilon \cap f^{-1}((0,\eta t]), \mathbb{Z}\right) \xrightarrow{\sim} \mathrm{H}^q(E, \mathbb{Z})$$

and the cospecialization morphism is defined in cohomology whenever the vanishing-cycle varieties are acyclic ($\mathrm{H}^0(E,\mathbb{Z}) = \mathbb{Z}$ and $\mathrm{H}^q(E,\mathbb{Z}) = 0$ for $q > 0$), which is expressed by saying that f is *locally acyclic*.

This chapter is devoted to the analogue of this situation for a smooth morphism of schemes in étale cohomology. In this setting, however, it is essential to restrict to torsion coefficients of order *prime to the residue characteristics*. Paragraph 5.1 gives generalities on locally acyclic morphisms and cospecialization maps. In Paragraph 5.2, we prove that a smooth morphism is locally acyclic. In Paragraph 5.3, this result is combined with those of the preceding chapter to obtain two applications: a specialization theorem for cohomology groups (the cohomology of the geometric fibres of a smooth proper morphism is locally constant), and a base change theorem for a smooth morphism.

Throughout what follows, we fix an integer n, and "scheme" means "scheme on which n is invertible." A "geometric point" will always mean an "algebraic geometric point" (2.3.1) $x : \mathrm{Spec}(k) \to X$, with k algebraically closed.

5.1 Locally acyclic morphisms

5.1.1 Notation

Given a scheme S and a geometric point s of S, we denote by $\widetilde{S}^s$ the spectrum of the strict localization of S at s.

Definition 5.1.2. *A geometric point t of S is called a* generization *of s if it is defined by an algebraic closure of the residue field of a point of $\widetilde{S}^s$. We also say that s is a* specialization *of t, and call the* specialization map *the S-morphism $t \to \widetilde{S}^s$.*

Definition 5.1.3. *Let $f : X \to S$ be a morphism of schemes. Let s be a geometric point of S, t a generization of s, x a geometric point of X over s, and $\widetilde{X}_t^x = \widetilde{X}^x \times_{\widetilde{S}^s} t$. Then $\widetilde{X}_t^x$ is called a* vanishing-cycle variety *of f at x.*

The morphism f is called locally acyclic *if the reduced cohomology of every vanishing-cycle variety $\widetilde{X}_t^x$ vanishes:*

$$\hat{\mathrm{H}}^{\bullet}(\widetilde{X}_t^x, \mathbb{Z}/n) = 0, \tag{5.1.3.1}$$

i.e. $\mathrm{H}^0(X_t^x, \mathbb{Z}/n) = \mathbb{Z}/n$ *and* $\mathrm{H}^q(\widetilde{X}_t^x, \mathbb{Z}/n) = 0$ *for* $q > 0$.

Lemma 5.1.4. *Let $f : X \to S$ be a locally acyclic morphism and let $g : S' \to S$ be a quasi-finite morphism (or a projective limit of quasi-finite morphisms). Then the morphism $f' : X' \to S'$ obtained from f by base change is locally acyclic.*

Indeed, every vanishing-cycle variety of f' is a vanishing-cycle variety of f.

Lemma 5.1.5. *Let $f : X \to S$ be a locally acyclic morphism. For every geometric point t of S giving rise to a cartesian diagram*

$$\begin{array}{ccc} X_t & \xrightarrow{\varepsilon'} & X \\ \downarrow & & \downarrow f \\ t & \xrightarrow{\varepsilon} & S \end{array}$$

one has $\varepsilon'_*\mathbb{Z}/n = f^*\varepsilon_*\mathbb{Z}/n$ and $\mathsf{R}^q\varepsilon'_*\mathbb{Z}/n = 0$ for $q > 0$.

Let $\bar{S}$ be the closure of $\varepsilon(t)$, let S' be the normalization of $\bar{S}$ in $k(t)$, and consider the cartesian diagram

$$\begin{array}{ccccc} X_t & \xrightarrow{f'} & X' & \xrightarrow{\alpha'} & X \\ \downarrow & & \downarrow f' & & \downarrow f \\ t & \xrightarrow{i} & S' & \xrightarrow{\alpha} & S \end{array}$$

The local rings of S' are normal with separably closed fraction fields. They are therefore strictly henselian, and the local acyclicity of f' (5.1.4) gives $f'_*\mathbb{Z}/n = \mathbb{Z}/n$ and $\mathsf{R}^q i'_*\mathbb{Z}/n = 0$ for $q > 0$. Since α is integral, it follows that

$$\mathsf{R}^q\varepsilon'_*\mathbb{Z}/n = \alpha'_*\mathsf{R}^q i'_*\mathbb{Z}/n = \alpha'_* f'^*\mathsf{R}^q i_*\mathbb{Z}/n = f^*\alpha_*\mathsf{R}^q i_*\mathbb{Z}/n = f^*\mathsf{R}^q\varepsilon_*\mathbb{Z}/n,$$

which proves the lemma.

5.1.6

Given a locally acyclic morphism $f : X \to S$ and a specialization map $t \to \widetilde{S}^s$, we shall define canonical homomorphisms, called cospecialization maps,

$$\mathrm{cosp}^\bullet : \mathrm{H}^\bullet(X_t, \mathbb{Z}/n) \to \mathrm{H}^\bullet(X_s, \mathbb{Z}/n),$$

relating the cohomology of the general fibre $X_t = X \times_S t$ to that of the special fibre $X_s = X \times_X s$.

Consider the cartesian diagram

$$\begin{array}{ccccc} X_t & \xrightarrow{\varepsilon'} & \widetilde{X} & \longleftarrow & X_s \\ \downarrow & & \downarrow{\scriptstyle f'} & & \downarrow \\ t & \xrightarrow{\varepsilon} & \widetilde{S}^s & \longleftarrow & s \end{array}$$

obtained from f by base change. By (5.1.4), f' is again locally acyclic. The definition of local acyclicity immediately shows that the restrictions to X_s of the sheaves $\mathsf{R}^q\varepsilon'_*\mathbb{Z}/n$ are $\mathbb{Z}/n$ for $q = 0$ and 0 for $q > 0$. By (5.1.5), we even know that $\mathsf{R}^q\varepsilon'_*\mathbb{Z}/n = 0$ for $q > 0$. We define $\mathrm{cosp}^\bullet$ as the composite map

$$\mathrm{H}^\bullet(X_t, \mathbb{Z}/n) \simeq \mathrm{H}^\bullet(X, \varepsilon'_*\mathbb{Z}/n) \to \mathrm{H}^\bullet(X_s, \mathbb{Z}/n). \tag{5.1.6.1}$$

Variant Let $\bar{S}$ be the closure of $\varepsilon(t)$ in $\widetilde{S}^s$, let S' be the normalization of $\bar{S}$ in $k(t)$, and let X'/S' be obtained from X/S by base change. Diagram (5.1.6.1) may also be written

$$\mathrm{H}^\bullet(X_t, \mathbb{Z}/n) \simeq \mathrm{H}^\bullet(X', \mathbb{Z}/n) \to \mathrm{H}^\bullet(X_s, \mathbb{Z}/n).$$

Theorem 5.1.7. *Let S be a locally noetherian scheme, s a geometric point of S, and $f : X \to S$ a morphism. Suppose that*

a) f is locally acyclic,

b) for every specialization map $t \to \widetilde{S}^s$ and every $q \geqslant 0$, the cospecialization maps $\mathrm{H}^q(X_t, \mathbb{Z}/n) \to \mathrm{H}^q(X_s, \mathbb{Z}/n)$ are bijective.

Then the canonical homomorphism $(\mathsf{R}^q f_*\mathbb{Z}/n)_s \to \mathrm{H}^q(X_s, \mathbb{Z}/n)$ is bijective for every $q \geqslant 0$.

To prove the theorem, we may clearly suppose that $S = \widetilde{S}^s$. We shall in fact show that, for every sheaf of $\mathbb{Z}/n\mathbb{Z}$-modules $\mathscr{F}$ on S, the canonical homomorphism $\varphi^q(\mathscr{F}) : (\mathsf{R}^q f_* f^*\mathscr{F})_s \to \mathrm{H}^q(X_s, f^*\mathscr{F})$ is bijective.

Every sheaf of $\mathbb{Z}/n\mathbb{Z}$-modules is a filtered direct limit of constructible sheaves of $\mathbb{Z}/n\mathbb{Z}$-modules (4.3.3). Moreover, every constructible sheaf of $\mathbb{Z}/n\mathbb{Z}$-modules embeds in a sheaf of the form $\prod i_{\lambda *}C_\lambda$, where $i_\lambda : t_\lambda \to S$ is a finite family of generizations of s and C_λ is a free $\mathbb{Z}/n\mathbb{Z}$-module of finite rank on t_λ. By the definition of the cospecialization maps, condition b) says that the homomorphisms $\varphi^q(\mathscr{F})$ are bijective when $\mathscr{F}$ has this form.

We conclude by a variant of Lemma (4.3.6):

Lemma 5.1.8. *Let $\mathcal{C}$ be an abelian category in which filtered direct limits exist. Let $\varphi^\bullet : T^\bullet \to T'^\bullet$ be a morphism of cohomological functors commuting with filtered direct limits, defined on $\mathcal{C}$ with values in the category of abelian groups. Suppose that there are two subsets $\mathcal{D}$ and $\mathcal{E}$ of the objects of $\mathcal{C}$ such that:*

a) every object of $\mathcal{C}$ is a filtered direct limit of objects belonging to $\mathcal{D}$,

b) every object belonging to $\mathcal{D}$ is contained in an object belonging to $\mathcal{E}$.

Then the following conditions are equivalent:

(i) $\varphi^q(A)$ *is bijective for every* $q \geqslant 0$ *and every* $A \in \mathrm{Ob}\,\mathcal{C}$.

(ii) $\varphi^q(M)$ *is bijective for every* $q \geqslant 0$ *and every* $M \in \mathcal{E}$.

The proof of the lemma proceeds by passage to the direct limit, induction on q, and repeated application of the five lemma to the diagram of exact cohomology sequences deduced from an exact sequence $0 \to A \to M \to A' \to 0$, with $A \in \mathcal{D}$, $M \in \mathcal{E}$, and $A' \in \mathrm{Ob}\,\mathcal{C}$.

Corollary 5.1.9. *Let* S *be the spectrum of a strictly henselian noetherian local ring and let* $f : X \to S$ *be a locally acyclic morphism. Suppose that for every geometric point* t *of* S *one has* $\mathrm{H}^0(X_t, \mathbb{Z}/n) = \mathbb{Z}/n$ *and* $\mathrm{H}^q(X_t, \mathbb{Z}/n) = 0$ *for* $q > 0$ *(in other words, the geometric fibres of* f *are acyclic). Then* $f_*\mathbb{Z}/n\mathbb{Z}/n$ *and* $\mathsf{R}^q f_*\mathbb{Z}/n = 0$ *for* $q > 0$.

Corollary 5.1.10. *Let* $f : X \to Y$ *and* $g : Y \to X$ *be morphisms of locally noetherian schemes. If* f *and* g *are locally acyclic, then so is* $g \circ f$.

We may suppose that X, Y, and Z are strictly local and that f and g are local morphisms. It is then enough to show that, if z is an algebraic geometric point of Z, then $\mathrm{H}^0(X_z, \mathbb{Z}/n) = \mathbb{Z}/n$ and $\mathrm{H}^q(X_z, \mathbb{Z}/n) = 0$ for $q > 0$.

Since g is locally acyclic, one has $\mathrm{H}^0(Y_z, \mathbb{Z}/n) = \mathbb{Z}/n$ and $\mathrm{H}^q(Y_z, \mathbb{Z}/n) = 0$ for $q > 0$. Moreover, the morphism $f_z : X_z \to Y_z$ is locally acyclic (5.1.4), and its geometric fibres are acyclic because they are vanishing-cycle varieties of f. By (5.1.9), $\mathsf{R}^q f_{z*}\mathbb{Z}/n = 0$ for $q > 0$. In addition, $f_{z*}\mathbb{Z}/n$ is constant with fibre $\mathbb{Z}/n$ on Y_z. The result follows from the Leray spectral sequence for f_z.

5.2 Local acyclicity of a smooth morphism

Theorem 5.2.1. *A smooth morphism is locally acyclic.*

Let $f : X \to S$ be a smooth morphism. The assertion is local for the étale topology on X and S, so we may suppose that X is standard affine space of dimension d over S. By passage to the limit, we may suppose that S is noetherian, and the transitivity of local acyclicity (5.1.10) shows that it suffices to treat $d = 1$.

Let s be a geometric point of S and x a geometric point of X centred at a closed point of X_s. We must show that the geometric fibres of $\widetilde{X}^x \to \widetilde{S}^s$ are acyclic. Henceforth put $S = \widetilde{S}^s = \mathrm{Spec}(A)$ and $X = \widetilde{X}^x$. Then $X \simeq \mathrm{Spec}\, A\{T\}$, where $A\{T\}$ is the henselization of $A[T]$ at the point $T = 0$ above s.

If t is a geometric point of S, the fibre X_t is a projective limit of smooth affine curves over t. Thus $\mathrm{H}^q(X_t, \mathbb{Z}/n) = 0$ for $q \geqslant 0$, and it suffices to show that $\mathrm{H}^0(X_t, \mathbb{Z}/n) = \mathbb{Z}/n$ and $\mathrm{H}^1(X_t, \mathbb{Z}/n) = 0$ for n prime to the residue characteristic of S. This follows from the next two propositions.

Proposition 5.2.2. *Let* A *be a strictly henselian local ring,* $S = \mathrm{Spec}(A)$*, and* $X = \mathrm{Spec}\, A\{T\}$*. Then the geometric fibres of* $X \to S$ *are connected.*

By passage to the limit, we may reduce to the case in which A is a strict henselization of a finitely generated $\mathbb{Z}$-algebra.

Let $\bar{t}$ be a geometric point of S lying over t, and let k' be a finite separable extension of $k(t)$ in $k(\bar{t})$. Put $t' = \mathrm{Spec}(k')$ and $X_{t'} = X \times_S \mathrm{Spec}(k')$. We must check that, for all $\bar{t}$ and t', $X_{t'}$ is connected (by which we mean connected and nonempty). Let A' be the normalization of A in k', i.e. the ring of elements of k' integral over the image of A in $k(t)$. One has $A\{t\} \otimes_A A' \xrightarrow{\sim} A'\{T\}$: indeed, the left-hand side is henselian local (because A' is finite over A and local) and is a limit of local étale algebras over $A'\{T\} = A\{T\} \otimes_A A'$. Thus $X_{t'}$ is still the fibre at t' of $X = \mathrm{Spec}\,(A'\{T\})$ over $S' = \mathrm{Spec}(A')$. The local scheme X' is normal, hence integral; its localization $X_{t'}$ is still integral, and a fortiori connected.

Proposition 5.2.3. *Let A be a strictly henselian local ring, $S = \mathrm{Spec}(A)$, and $X = \mathrm{Spec}\,(A\{T\})$. Let $\bar{t}$ be a geometric point of S and $X_{\bar{t}}$ the corresponding geometric fibre. Then every Galois étale covering of $X_{\bar{t}}$ of order prime to the characteristic of the residue field of A is trivial.*

Lemma 5.2.4 (Zariski–Nagata purity theorem in dimension 2)**.** *Let C be a regular local ring of dimension 2 and let C' be a finite normal C-algebra étale over the open complement of the closed point of* $\mathrm{Spec}(C)$*. Then C' is étale over C.*

Indeed, C' is normal of dimension 2, and hence $\mathrm{prof}(C') = 2$. Since $\mathrm{prof}(C') + \dim \mathrm{proj}(C') = \dim(C) = 2$, it follows that C' is free over C. The set of points of C where C' is ramified is then defined by an equation, the discriminant; since it contains no point of height 1, it is empty.

Lemma 5.2.5 (Special case of Abhyankar's lemma)**.** *Let $S = \mathrm{Spec}(V)$ be a trait, let π be a uniformizer, let η be the generic point of S, let X be smooth over S, irreducible, and of relative dimension 1, let $\widetilde{X}_\eta$ be a Galois étale covering of X_η of degree n invertible on S, and let $S_1 = \mathrm{Spec}\left(V[\pi^{1/n}]\right)$. Use a subscript $(-)_1$ to denote base change from S to S_1. Then $\widetilde{X}_{1\eta}$ extends to an étale covering of X_1.*

Let $\widetilde{X}_1$ be the normalization of X_1 in $\widetilde{X}_{1\eta}$. By the structure of the tame inertia groups of the discrete valuation rings obtained by localizing X at the generic points of the special fibre X_s, $\widetilde{X}_1$ is étale over X_1 on the general fibre and at the generic points of the special fibre. By (5.2.4), it is étale everywhere.

5.2.6

Let t denote the point over which $\bar{t}$ lies. We are free to replace A by the normalization of A in a finite separable extension $k(t')$ of $k(t)$ in $k(\bar{t})$ (cf. 5.2.2). This and a preliminary passage to the limit allow us to suppose that

a) A is normal and noetherian, and t is the generic point of S.

b) The étale covering under consideration of $X_{\bar{t}}$ comes from an étale covering of X_t.

c) It comes from an étale covering $\widetilde{X}_U$ of the inverse image X_U of a nonempty open subset U of S (this follows from b): t is the limit of the U).

d) The complement of U has codimension $\geqslant 2$ (at the price of enlarging $k(t)$, by applying (5.2.5) to the discrete valuation rings obtained by localizing S at the points of $S \smallsetminus U$ of codimension 1 in S; there are only finitely many such points).

e) The covering $\widetilde{X}_U$ is trivial over the subscheme $T = 0$. (This may require enlarging $k(t)$ once more.)

Under these conditions, we shall show that the covering $\widetilde{X}_U$ is trivial.

Lemma 5.2.7. *Let A be a normal noetherian strictly henselian local ring, let U be an open subset of* $\mathrm{Spec}(A)$ *whose complement has codimension $\geqslant 2$, let V be its inverse image in $X = \mathrm{Spec}\,(A\{T\})$, and let V' be an étale covering of V. If V' is trivial over $T = 0$, then V' is trivial.*

Let $B = \Gamma(V', \mathscr{O})$. Since V' is the inverse image of V in $\mathrm{Spec}(B)$, it suffices to show that B is finite étale over $A\{T\}$ (and hence split, since $A\{T\}$ is strictly henselian). Let $\widehat{X} = A[\![T]\!]$, and denote by $(-)^\wedge$ base change from X to $\widehat{X}$. The scheme $\widehat{X}$ is faithfully flat over X. Hence $\Gamma(\widehat{V}', \mathscr{O}) = B \otimes_{A\{T\}} A[\![T]\!]$, and it suffices to show that this ring $\widehat{B}$ is finite étale over $A[\![T]\!]$.

Let V_m (resp. V'_m) be the subscheme of $\widehat{V}$ (resp. $\widehat{V}'$) defined by $T^{m+1} = 0$. By hypothesis, V'_0 is a trivial covering of V_0: a sum of n copies of V_0. The same is true of V'_m/V_m, because étale coverings are insensitive to nilpotents. We obtain

$$\varphi : \Gamma(\widehat{V}', \mathscr{O}) \to \varprojlim_m \Gamma(V'_m, \mathscr{O}) = \left(\varprojlim_m \Gamma(V, \mathscr{O})\right)^n .$$

By hypothesis, the complement of U has depth $\geqslant 2$: one has $\Gamma(V_m, \mathscr{O}) = A[T]/(T^{m+1})$, and φ is a homomorphism from $\widehat{B}$ to $A[\![T]\!]^n$. Over U, it provides n distinct sections of $\widehat{V}'/\widehat{V}$; hence $\widehat{V}'$ is trivial, a sum of n copies of $\widehat{V}$. Since the complement of $\widehat{V}$ in $\widehat{X}$ still has codimension $\geqslant 2$ (and therefore depth $\geqslant 2$), it follows that $\widehat{B} = A[\![T]\!]^n$, proving the lemma.

5.3 Applications

Theorem 5.3.1 (Specialization of cohomology groups)**.** *Let $f : X \to S$ be a proper locally acyclic morphism, for example a smooth proper morphism. Then the sheaves $\mathsf{R}^q f_* \mathbb{Z}/n$ are locally constant constructible, and for every specialization map $t \to \widetilde{S}^s$, the cospecialization maps $\mathrm{H}^q(X_t, \mathbb{Z}/n) \to \mathrm{H}^q(X_s, \mathbb{Z}/n)$ are bijective.*

This follows immediately from the definition of the cospecialization maps and the finiteness and proper base change theorems.

Theorem 5.3.2 (Base change by a smooth morphism)**.** *Let*

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f} \\ S' & \xrightarrow{g} & S \end{array}$$

be a cartesian diagram with g smooth. For every sheaf $\mathscr{F}$ on X that is torsion of order prime to the residue characteristics of S, one has

$$g^* \mathsf{R}^q f_* \mathscr{F} \xrightarrow{\sim} \mathsf{R}^q f'_* (g'^* \mathscr{F}).$$

After passing to an open covering of X, we reduce to the case where X is affine, and then, by passage to the limit, to the case where X is of finite type over S. The morphism f then factors as an open immersion $j : X \to \bar{X}$ followed by a proper morphism $\bar{f} : \bar{X} \to S$. The Leray spectral sequence for $\bar{f} \circ j$ and the proper base change theorem show that it suffices to prove the theorem when $X \to S$ is an open immersion.

In this case, if $\mathscr{F}$ has the form $\varepsilon_* C$, where $\varepsilon : t \to X$ is a geometric point of X, the theorem is a corollary of (5.1.5). The general case follows from Lemma (5.1.8).

Corollary 5.3.3. *Let K/k be an extension of separably closed fields, let X be a k-scheme, and let n be an integer prime to the characteristic of k. Then the canonical map $\mathrm{H}^q(X, \mathbb{Z}/n) \to \mathrm{H}^q(X_K, \mathbb{Z}/n)$ is bijective for every $q \geqslant 0$.*

It suffices to observe that $\bar{K}$ is a direct limit of smooth $\bar{k}$-algebras.

Theorem 5.3.4 (Relative purity)**.** *Let*

$$\begin{array}{ccccc} U & \xrightarrow{j} & X & \xleftarrow{i} & Y \\ & \searrow & \downarrow{\scriptstyle f} & \swarrow{\scriptstyle h} & \\ & & S & & \end{array} \tag{5.3.4.1}$$

be a commutative diagram with f smooth of pure relative dimension N, h smooth of pure relative dimension $N-1$, i a closed immersion, and $U = X \smallsetminus Y$. If n is prime to the residue characteristics of S, then

$$\begin{aligned} j_*\mathbb{Z}/n &= \mathbb{Z}/n \\ \mathsf{R}^1 j_*\mathbb{Z}/n &= \mathbb{Z}/n(-1)_Y \\ \mathsf{R}^q j_*\mathbb{Z}/n &= 0 \qquad \textit{for } q \geqslant 2 \end{aligned}$$

In these formulas, $\mathbb{Z}/n(-1)$ denotes the $\mathbb{Z}/n$-dual of $\boldsymbol{\mu}_n$. If t is a local equation for Y, the isomorphism $\mathsf{R}^1 j_*\mathbb{Z}/n \simeq \mathbb{Z}/n(-1)_Y$ is defined by the map $a : \mathbb{Z}/n \to \mathsf{R}^1 j_*\boldsymbol{\mu}_n$ sending 1 to the class of the $\boldsymbol{\mu}_n$-torsor of nth roots of t.

The question is local. This allows us to replace (X, Y) by a locally isomorphic pair, for example

$$\begin{array}{ccccc} \mathbb{A}^1_T & \xrightarrow{j} & \mathbb{P}^1_T & \xleftarrow{i} & T \\ & \searrow_{g} & \downarrow{\scriptstyle f} & \swarrow & \\ & & T & & \end{array}$$

with $T = \mathbb{A}^{n-1}_S$ and $i =$ the section at infinity. Corollary (5.1.9) applies to g and gives $\mathsf{R}^q g_{\mathbb{Z}}/n = \mathbb{Z}/n$ for $q = 0$ and 0 for $q > 0$. For f, on the other hand, (4.6.2.1) gives

$$\mathsf{R}^q f_*\mathbb{Z}/n = \mathbb{Z}/n, 0, \mathbb{Z}/n(-1), 0 \text{ for } q > 2.$$

It is readily checked that $j_*\mathbb{Z}/n = \mathbb{Z}/n$, and that the $\mathsf{R}^q j_*\mathbb{Z}/n = 0$ are concentrated on $i(T)$ for $q > 0$. The Leray spectral sequence $E_2^{pq} = \mathsf{R}^p f_* \mathsf{R}^q j_*\mathbb{Z}/n \Rightarrow \mathsf{R}^{p+q} g_*\mathbb{Z}/n$ therefore reduces to

$$\begin{array}{ccccccc} i^*\mathsf{R}^q j_*\mathbb{Z}/n & & 0 & & \cdots & & \\ \\ i^*\mathsf{R}^1 j_*\mathbb{Z}/n & & 0 & & \cdots & & \\ & \searrow^{d_2} & & & & & \\ \mathbb{Z}/n & & 0 & & \mathbb{Z}/n(-1) & 0 & \cdots \end{array}$$

$\mathsf{R}^q j_*\mathbb{Z}/n = 0$ for $q \geqslant 0$, and $\mathsf{R}^q j_*\mathbb{Z}/n$ is the extension by zero of a locally free sheaf of rank one on T (isomorphic, via d_2, to $\mathbb{Z}/n(-1)$). Since the map a defined above is injective (as may be checked fibre by fibre), it is an isomorphism, which proves (5.3.4).

5.3.5

We refer to [2, XVI.4,5] for proofs of the following applications of the acyclicity theorem (5.2.1).

Theorem 5.3.6. *Let $f : X \to S$ be a morphism of schemes of finite type over $\mathbb{C}$ and let $\mathscr{F}$ be a constructible sheaf on X. Then*

$$(\mathsf{R}^q f_* \mathscr{F})^{\mathrm{an}} \sim \mathsf{R}^q f_*^{\mathrm{an}}(\mathscr{F}^{\mathrm{an}})$$

(cf. 4.6.3: for ordinary cohomology it is necessary to assume that $\mathscr{F}$ is constructible, not merely torsion).

Theorem 5.3.7. *Let $f : X \to S$ be a morphism of schemes of finite type over a field k of characteristic 0, and let $\mathscr{F}$ be a constructible sheaf on X. Then the $\mathsf{R}^q f_* \mathscr{F}$ are also constructible.*

The proof uses resolution of singularities and (5.3.4). It is generalized to a morphism of finite type between excellent schemes of characteristic 0 in [2, XIX.5]. Another proof, independent of resolution, is given in this volume (Finiteness theorems in ℓ-adic cohomology, 1.1) and applies to a morphism of schemes of finite type over a field or over a Dedekind ring.

6 Poincaré duality

6.1 Introduction

Let X be an oriented topological manifold of pure dimension N, and suppose that X admits a finite open covering $\mathcal{U} = (U_i)_{1 \leqslant i \leqslant K}$ such that every nonempty intersection of the open subsets U_i is homeomorphic to a ball. For such a manifold, the Poincaré duality theorem can be presented as follows:

A The cohomology of X is the Čech cohomology associated with the covering $\mathcal{U}$. It is the cohomology of the complex

$$0 \to \mathbb{Z}^{A_0} \to \mathbb{Z}^{A_1} \to \cdots \tag{1}$$

where $A_k = \{(i_0, \ldots, i_k) : i_0 < \cdots < i_k \text{ and } U_{i_0} \cap \cdots \cap U_{i_k} \neq \varnothing\}$.

B For $a \in A_k$, $a = (i_0, \ldots, i_k)$, let $U_a = U_{i_1} \cap \cdots \cap U_{i_k}$ and let j_a be the inclusion of U_a into X. The constant sheaf $\mathbb{Z}$ on X admits the (left) resolution

$$\cdots \longrightarrow \bigoplus_{a \in A_1} j_{a!}\mathbb{Z} \longrightarrow \bigoplus_{a \in A_0} j_{a!}\mathbb{Z} \longrightarrow 0 \tag{2}$$

$$\downarrow$$

$$\mathbb{Z}.$$

The compactly supported cohomology $\mathrm{H}_c^\bullet(X, j_{a!}\mathbb{Z})$ is precisely the cohomology with proper support of the (oriented) ball U_a:

$$\mathrm{H}_c^i(X, j_{a!}\mathbb{Z}) = \begin{cases} 0 & \text{if } i \neq N \\ \mathbb{Z} & \text{if } i = N \end{cases}$$

The hypercohomology spectral sequence for the complex (2) and cohomology with proper support therefore says that $\mathrm{H}_c^i(X)$ is the $(i - N)$th cohomology group of the complex

$$\cdots \to \mathbb{Z}^{A_1} \to \mathbb{Z}^{A_0} \to 0. \tag{3}$$

This complex is dual to the complex (1), whence Poincaré duality.

The essential points of this construction are

a) the existence of a theory of cohomology with proper support;

b) the fact that every point x of a manifold X of pure dimension N has a fundamental system of open neighbourhoods U for which

$$\mathrm{H}^i_c(U) = \begin{cases} 0 & \text{for } i \neq N, \\ \mathbb{Z} & \text{for } i = N. \end{cases} \tag{4}$$

Poincaré duality in étale cohomology can be constructed on this model. For X smooth of pure dimension N over an algebraically closed field k, n invertible on X, and x a closed point of X, the key point is to calculate the projective limit over the étale neighbourhoods U of x:

$$\varprojlim \mathrm{H}^i_c(U, \mathbb{Z}/n) = \begin{cases} 0 & \text{if } i \neq 2N \\ \mathbb{Z}/n & \text{if } i = 2N. \end{cases} \tag{5}$$

Just as for topological manifolds one must first treat directly the case of an open ball (or even simply the interval $(0,1)$), here one must first treat directly the case of curves (6.2). The local acyclicity theorem for smooth morphisms then reduces (5) to this special case (6.3).

The isomorphisms (4) and (5) are not canonical: they depend on the choice of an *orientation* of X. For n invertible on a scheme X, $\boldsymbol{\mu}_n$ is a sheaf of free $\mathbb{Z}/n$-modules of rank one. We denote its Nth tensor power by $\mathbb{Z}/n(N)$ ($N \in \mathbb{Z}$). The intrinsic form of the second line of (5) is

$$\varprojlim \mathrm{H}^{2N}_c(U, \mathbb{Z}/n(N)) = \mathbb{Z}/n, \tag{6}$$

and $\mathbb{Z}/n(N)$ is called the *orientation sheaf* of X. Since the sheaf $\mathbb{Z}/n(N)$ is constant and isomorphic to $\mathbb{Z}/n$, it may be taken outside the limit sign (with N fixed), and one may instead write

$$\varprojlim \mathrm{H}^{2N}_c(U, \mathbb{Z}/n) = \mathbb{Z}/n(-N), \tag{7}$$

and Poincaré duality will take the form of a perfect duality, with values in $\mathbb{Z}/n(-N)$, between $\mathrm{H}^i(X, \mathbb{Z}/n)$ and $\mathrm{H}^{2N-i}_c(X, \mathbb{Z}/n)$.

6.2 The case of curves

6.2.1

Let $\bar{X}$ be a smooth projective curve over an algebraically closed field k, and let n be invertible on $\bar{X}$. The proof of (3.3.5) gives, for connected $\bar{X}$, a canonical isomorphism

$$\mathrm{H}^2(\bar{X}, \boldsymbol{\mu}_n) = \mathrm{Pic}(\bar{X})/n\,\mathrm{Pic}(\bar{X}) \xrightarrow[\sim]{\deg} \mathbb{Z}/n$$

Let D be a reduced divisor of $\bar{X}$ and let $X = \bar{X} \smallsetminus D$:

$$X \xhookrightarrow{\ j\ } \bar{X} \xhookleftarrow{\ i\ } D.$$

The exact sequence $0 \to j_!\boldsymbol{\mu}_n \to \boldsymbol{\mu}_n \to i_*\boldsymbol{\mu}_n \to 0$ and the fact that $\mathrm{H}^i(\bar{X}, i_*\boldsymbol{\mu}_n) = \mathrm{H}^i(D, \boldsymbol{\mu}_n) = 0$ for $i > 0$ give an isomorphism

$$\mathrm{H}^2_c(X, \boldsymbol{\mu}_n) = \mathrm{H}^2(\bar{X}, j_!\boldsymbol{\mu}_n) \xrightarrow{\sim} \mathrm{H}^2(\bar{X}, \boldsymbol{\mu}_n) \xrightarrow{\sim} \mathbb{Z}/n.$$

For disconnected $\bar{X}$, similarly

$$\mathrm{H}^2_c(X, \boldsymbol{\mu}_n) = (\mathbb{Z}/n)^{\pi_0(X)}$$

and the *trace morphism* is defined to be the sum

$$\mathrm{tr} : \mathrm{H}^2_c(X, \boldsymbol{\mu}_n) \simeq (\mathbb{Z}/n)^{\pi_0(X)} \xrightarrow{\ \Sigma\ } \mathbb{Z}/n.$$

Theorem 6.2.2. *The pairing* $\mathrm{tr}(a \smile b)$ *identifies each of the two groups* $\mathrm{H}^i(X, \mathbb{Z}/n)$ *and* $\mathrm{H}_c^{2-i}(X, \boldsymbol{\mu}_n)$ *with the dual (with values in* $\mathbb{Z}/n$*) of the other.*

Transcendental proof. Suppose that $\bar{X}$ is a smooth projective curve over a trait S and that $j : X \hookrightarrow \bar{X}$ is the inclusion of the complement of a divisor D étale over S. The cohomology (resp. cohomology with proper support) of the special and generic geometric fibres of X/S are "the same," i.e. the fibres of locally constant sheaves on S. This follows from the analogous facts for $\bar{X}$ and D, by means of the exact sequence $0 \to j_!\mathbb{Z}/n \to \mathbb{Z}/n \to \mathbb{Z}/n_D \to 0$ (for cohomology with proper support) and the formulas $j_*\mathbb{Z}/n = \mathbb{Z}/n$, $\mathsf{R}^1 j_*\mathbb{Z}/n \simeq \mathbb{Z}/n_D(-1)$, and $\mathsf{R}^i j_*\mathbb{Z}/n = 0$ $(i \geqslant 2)$ (for ordinary cohomology) (5.3.4).

This specialization principle reduces (6.2.2) to the case in which k has characteristic 0. By (5.3.3), this case reduces to $k = \mathbb{C}$. Finally, when $k = \mathbb{C}$, the groups $\mathrm{H}^\bullet(X, \mathbb{Z}/n)$ and $\mathrm{H}_c^\bullet(X, \boldsymbol{\mu}_n)$ agree with the groups of the same name calculated for the classical topological space X_{cl}, and, through the isomorphism $\mathbb{Z}/n \to \boldsymbol{\mu}_n : x \mapsto \exp\left(\frac{2\pi i x}{n}\right)$, the trace morphism is identified with "integration over the fundamental class." Thus (6.2.2) follows from Poincaré duality for X_{cl}.

6.2.3 Algebraic proof

For a very economical proof, see (Duality, §2). Here is another, related to the autoduality of the Jacobian.

Return to the notation of (6.2.1). We may suppose—and do suppose—that X is connected. The cases $i = 0$ and $i = 2$ being trivial, we also suppose that $i = 1$. Define ${}_D\mathbb{G}_m$ by the exact sequence $0 \to {}_D\,\mathbb{G}_m \to \mathbb{G}_m \to i_*\mathbb{G}_m \to 0$ (sections of $\mathbb{G}_m$ congruent to 1 mod D). The group $\mathrm{H}^1(\bar{X}, {}_D\,\mathbb{G}_m)$ classifies invertible sheaves on $\bar{X}$ trivialized on D. It is the group of points of $\mathrm{Pic}_D(\bar{X})$, an extension of $\mathbb{Z}$ (the degree) by the group of points of Rosenlicht's generalized Jacobian $\mathrm{Pic}_D^0(\bar{X})$ (corresponding to conductor 1 at each point of D), itself an extension of the abelian variety $\mathrm{Pic}^0(\bar{X})$ by the torus $\mathbb{G}_m^D/(\text{diagonal } \mathbb{G}_m)$.

a) The exact sequence $0 \to j_!\boldsymbol{\mu}_n \to {}_D\,\mathbb{G}_m \xrightarrow{n} {}_D\,\mathbb{G}_m \to 0$ gives an isomorphism

$$\mathrm{H}_c^1(X, \boldsymbol{\mu}_n) = \mathrm{Pic}_D^0(\bar{X})_n. \tag{6.2.3.1}$$

b) The map sending $x \in X(k)$ to the class of the invertible sheaf $\mathscr{O}(x)$ on $\bar{X}$, trivialized by 1 on D, comes from a morphism

$$f : X \to \mathrm{Pic}_D(\bar{X}).$$

For the remainder, fix a base point 0 and put $f_0(x) = f(x) - f(0)$. For every homomorphism $v : \mathrm{Pic}_D^0(\bar{X})_n \to \mathbb{Z}/n$, let $\bar{v} \in \mathrm{H}^1\left(\mathrm{Pic}_D^0(\bar{X}), \mathbb{Z}/n\right)$ be the image under v of the class in $\mathrm{H}^1\left(\mathrm{Pic}_D^0(\bar{X}), \mathrm{Pic}_D^0(\bar{X})_n\right)$ of the torsor defined by the extension

$$0 \longrightarrow \mathrm{Pic}_D^0(\bar{X})_n \longrightarrow \mathrm{Pic}_D^0(\bar{X}) \xrightarrow{n} \mathrm{Pic}_D^0(\bar{X}) \longrightarrow 0$$

Geometric class field theory (as presented in Serre [33]) shows that the map $v \mapsto f_0^*(\bar{v})$

$$\hom\left(\mathrm{Pic}_D^0(\bar{X})_n, \mathbb{Z}/n\right) \to \mathrm{H}^1(X, \mathbb{Z}/n) \tag{6.2.3.2}$$

is an isomorphism. To deduce (6.2.2) from (6.2.3.1) and (6.2.3.2), it remains to know that

$$\mathrm{tr}\left(u \smile f_0^*(\bar{v})\right) = -v(u). \tag{6.2.2.3}$$

6.3 The general case

Let X be a smooth algebraic variety of pure dimension N over an algebraically closed field k. To state the Poincaré duality theorem, one must first define the trace morphism

$$\mathrm{tr} : \mathrm{H}_c^{2N}(X, \mathbb{Z}/n(N)) \to \mathbb{Z}/n.$$

The definition is a painful unwinding starting from the case of curves [2, XVIII §2]. One then has:

Theorem 6.3.1. *The pairing* $\mathrm{tr}(a \smile b)$ *identifies each of the groups* $\mathrm{H}_c^i(X, \mathbb{Z}/n(N))$ *and* $\mathrm{H}^{2N-i}(X, \mathbb{Z}/n)$ *with the dual of the other.*

Let $x \in X$ be a closed point and let X_x be the strict localization of X at x. For U ranging over the étale neighbourhoods of x, put

$$\mathrm{H}_c^\bullet(X_x, \mathbb{Z}/n) = \varprojlim \mathrm{H}_c^\bullet(U, \mathbb{Z}/n). \tag{6.3.1.1}$$

It would be preferable to consider instead the pro-object "$\varprojlim$" $\mathrm{H}_c^\bullet(U, \mathbb{Z}/n)$, but since the groups involved are finite, the difference is inessential. As we tried to explain in the introduction, (6.3.1) follows from the facts that

$$\begin{gathered} \mathrm{H}_c^i(X_x, \mathbb{Z}/n) = 0 \text{ for } i \neq 2N \text{ and that} \\ \mathrm{tr} : \mathrm{H}_c^{2N}(X_x, \mathbb{Z}/n(N)) \xrightarrow{\sim} \mathbb{Z}/n \text{ is an isomorphism.} \end{gathered} \tag{6.3.1.2}$$

The case $N = 0$ is trivial. If $N > 0$, let Y_y be the strict localization at a closed point of a smooth scheme Y of pure dimension $N - 1$, and let $f : X_x \to Y_y$ be an essentially smooth morphism (of relative dimension one). The proof uses the Leray spectral sequence for cohomology with proper support for f to reduce to the case of curves. Because the "cohomology with proper support" under consideration is defined as limits (6.3.1.1), the existence of such a spectral sequence raises various passage-to-the-limit problems, treated in too much detail in [2, XVIII]. For every geometric point z of Y_y, one has

$$(\mathsf{R}^i f_! \mathbb{Z}/n)_z = \mathrm{H}_c^i(f^{-1}(z), \mathbb{Z}/n).$$

The geometric fibre $f^{-1}(z)$ is a projective limit of smooth curves over an algebraically closed field. It satisfies Poincaré duality. Its ordinary cohomology is given by the local acyclicity theorem for smooth morphisms:

$$\mathrm{H}^i(f^{-1}(z), \mathbb{Z}/n) = \begin{cases} \mathbb{Z}/n & \text{for } i = 0 \\ 0 & \text{for } i > 0. \end{cases}$$

By duality,

$$\mathrm{H}_c^i(f^{-1}(z), \mathbb{Z}/n) = \begin{cases} \mathbb{Z}/n(-1) & \text{for } i = 2 \\ 0 & \text{for } i \neq 2. \end{cases}$$

and the Leray spectral sequence becomes

$$\mathrm{H}_c^i(X_x, \mathbb{Z}/n(N)) = \mathrm{H}_c^{i-2}(Y_y, \mathbb{Z}/n(N-1)).$$

The result follows by induction on N.

6.4 Variants and applications

One can construct in étale cohomology a "duality formalism" (= functors $\mathsf{R}f_!$, $\mathsf{R}f_!$, and $\mathsf{R}f^!$ satisfying various compatibilities and adjunction formulas) parallel to the one that exists in coherent cohomology. In

this language, the results of the preceding paragraph can be rewritten as follows: if $f : X \to S$ is smooth of pure relative dimension N and $S = \mathrm{Spec}(k)$ with k algebraically closed, then

$$\mathsf{R}f^!\mathbb{Z}/n = \mathbb{Z}/n[2N](N).$$

This result holds without any hypothesis on S. It has the following corollary.

Corollary 6.4.1. *If f is smooth of pure relative dimension N and the sheaves $\mathsf{R}^i f_!\mathbb{Z}/n$ are locally constant, then the sheaves $\mathsf{R}^i f_*\mathbb{Z}/n$ are also locally constant, and*

$$\mathsf{R}^i f_*\mathbb{Z}/n = \underline{\hom}\left(\mathsf{R}^{2N-i} f_!\mathbb{Z}/n(N), \mathbb{Z}/n\right).$$

In particular, under the hypotheses of the corollary, the sheaves $\mathsf{R}^i f_*\mathbb{Z}/n$ are constructible. From this one can show that, if S is of finite type over the spectrum of a field or of a Dedekind ring, then, for every morphism of finite type $f : X \to S$ and every constructible sheaf $\mathscr{F}$ on X, the sheaves $\mathsf{R}^i f_*\mathscr{F}$ are constructible (Finiteness theorems in ℓ-adic cohomology, 1.1).

Chapter 2

Report on the trace formula

In this text, I have attempted to present Grothendieck's cohomological theory of L-functions as directly as possible. I follow very closely some of the lectures given by Grothendieck at the IHES in the spring of 1966. In the spirit of this volume, no appeal will be made to SGA 5—apart from two references to passages in Exposé XI, which is otherwise independent of that seminar.

In §10 (pp. 81–90) of [13], the reader will find a summary of the theory in the crucial case of curves.

1 Some reminders

1.1 Notation

$p, q, \mathbb{F}, \mathbb{F}_q$: p is a prime number, $q = p^f$ a power of p, and $\mathbb{F}$ an algebraic closure of the prime field $\mathbb{F}_p$. For every power p^n of p, denote by $\mathbb{F}_{p^n}$ the subfield with p^n elements of $\mathbb{F}$.

X_0, X: An object over $\mathbb{F}_q$ will often be denoted by a symbol carrying a subscript 0. The same symbol without the 0 then denotes the object obtained from it by extension of scalars to $\mathbb{F}$. For example, if $\mathscr{F}_0$ is a sheaf on a scheme X_0 over $\mathbb{F}_q$, denote by $\mathscr{F}$ its inverse image on $X = X_0 \otimes_{\mathbb{F}_q} \mathbb{F}$.

F: If X_0 is a scheme over $\mathbb{F}_q$, the endomorphism of X_0 that "sends the point with coordinates x to the point with coordinates x^q" is called the *Frobenius morphism* and denoted by F: it is the identity on the underlying topological space and, for x a local section of the structure sheaf, $F^*x = x^q$.

The endomorphism of X obtained from it by extension of scalars is also denoted by F. On the set $X(\mathbb{F}) = X_0(\mathbb{F})$ of rational points of X, F acts as the Frobenius substitution $\varphi \in \mathrm{Gal}(\mathbb{F}/\mathbb{F}_q)$ defined by $\varphi(x) = x^q$. In particular, $X^F = X_0(\mathbb{F}_q)$.

In case of ambiguity, we shall write $F_{(q)}$ rather than F.

1.2 Frobenius correspondence

Let X_0 be a scheme over $\mathbb{F}_q$, and let $\mathscr{F}_0$ be a sheaf on X_0. I like to view the *Frobenius correspondence* (an F-endomorphism of $\mathscr{F}_0$) as follows:

$$F^* : F^*\mathscr{F}_0 \xrightarrow{\sim} \mathscr{F}_0 \tag{1.2.1}$$

Regard $\mathscr{F}_0$ as the sheaf of local sections of a space $[\mathscr{F}_0]$ étale over X_0 ($[\mathscr{F}_0]$ is an algebraic space in

the sense of M. Artin). The functoriality of F gives a commutative diagram

$$\begin{array}{ccc} [\mathscr{F}_0] & \xrightarrow{F} & [\mathscr{F}_0] \\ \downarrow & & \downarrow \\ X_0 & \xrightarrow{F} & X_0 \end{array}$$

Because $[\mathscr{F}_0]$ is étale over X_0, this diagram is Cartesian; it gives an isomorphism $[\mathscr{F}_0] \xrightarrow{\sim} F^*[\mathscr{F}_0]$ whose inverse is (1.2.1). We also denote by F^* the correspondences or morphisms deduced from F by extension of scalars or by functoriality, such as $F^* : \mathrm{H}_c^\bullet(X, \mathscr{F}) \to \mathrm{H}_c^\bullet(X, \mathscr{F})$.

For a formal definition, I refer to [21, XI.1,2]. Only the case $q = p$ is considered there, but the general case is treated in the same way.

1.3

The Frobenius correspondence is functorial in $(X_0, \mathscr{F}_0)$. If $f_0 : X_0 \to Y_0$ is a morphism of $\mathbb{F}_q$-schemes, $\mathscr{F}_0$ a sheaf on X_0, $\mathscr{G}_0$ a sheaf on Y_0, and $u \in \hom(f_0^*\mathscr{G}_0, \mathscr{F}_0)$ an f_0-morphism from $\mathscr{G}_0$ to $\mathscr{F}_0$, there is a commutative diagram of spaces $f_0F = Ff_0$, and above it a commutative diagram of sheaves

$$\begin{array}{ccc} X_0 & \xrightarrow{f_0} & Y_0 \\ \downarrow{\scriptstyle F} & & \downarrow{\scriptstyle F} \\ X_0 & \xrightarrow{f_0} & Y_0 \end{array} \qquad \begin{array}{ccc} \mathscr{F}_0 & \xleftarrow{u} & \mathscr{G}_0 \\ \uparrow{\scriptstyle F^*} & & \uparrow{\scriptstyle F^*} \\ \mathscr{F}_0 & \xleftarrow{} & \mathscr{G}_0 \end{array}$$

In particular, the correspondence on $f_{0*}\mathscr{F}_0$ deduced from the Frobenius correspondence of $(X_0, \mathscr{F}_0)$ is the Frobenius correspondence of $(U_0, f_{0*}\mathscr{F}_0)$.

1.4

The natural morphism $Y \to Y_0$ is a limit of étale morphisms. It follows that for every abelian sheaf $\mathscr{F}_0$ on X_0, the inverse images on Y of the $\mathsf{R}^i f_0\mathscr{F}_0$ are the $\mathsf{R}^i f_*\mathscr{F}$.

On $\mathsf{R}^i f_*\mathscr{F}$, one has

a) the correspondence $F^*\mathsf{R}^i f_*\mathscr{F} \xrightarrow{\sim} \mathsf{R}^i f_*\mathscr{F} \xrightarrow{F^*} \mathsf{R}^i f_*\mathscr{F}$ deduced by functoriality from the Frobenius correspondence;

b) the correspondence $F^*\mathsf{R}^i f_*\mathscr{F} \to \mathsf{R}^i f_*\mathscr{F}$ that is the inverse image on Y of the Frobenius correspondence on $\mathsf{R}^i i f_{0*}\mathscr{F}_0$.

It follows from (1.3) that these correspondences coincide. They induce the initial term of a Frobenius action on the entire spectral sequence

$$\mathrm{H}^p(Y, \mathsf{R}^q f_*\mathscr{F}) \to \mathrm{H}^{p+q}(X, \mathscr{F}).$$

Likewise for cohomology with proper support, and for the spectral sequence

$$\mathrm{H}_c^p(Y, \mathsf{R}^q f_*\mathscr{F}) \to \mathrm{H}_c^{p+q}(X, \mathscr{F})$$

1.5 Change of finite field

Let $(X_0, \mathscr{F}_0)$ be over $\mathbb{F}_q$, let n be an integer, and let $(X_1, \mathscr{F}_1)$ over $\mathbb{F}_{q^n}$ be obtained from $(X_0, \mathscr{F}_0)$ by extension of scalars. On the one hand there is the Frobenius correspondence $F_{(q)} : X_0 \to X_0$), $F_{(q)}^* : F_{(q)}^* \mathscr{F}_0 \to \mathscr{F}_0$, and on the other there is $F_{(q^n)} : X_1 \to X_1$, $F_{(q^n)}^* : F_{(q^n)}^* \mathscr{F}_1 \to \mathscr{F}_1$. It is easily verified that $F_{(q^n)}$ is obtained from the n-th power of $F_{(q)}$ by extension of scalars from $\mathbb{F}_q$ to $\mathbb{F}_{q^n}$; after extension of scalars to $\mathbb{F}$, one still has the same identity $F_{(q^n)} = F_{(q)}^n$ between endomorphisms of X and correspondences on X.

If x is a closed point of X_0, with $[k(x), \mathbb{F}_q] = n$, and $\bar{x} \in X_0(\mathbb{F}) = X(\mathbb{F})$ lies over x, then $\bar{x}$ is a fixed point of $F_{(q^n)} = F_{(q)}^n$. Denote by F_x^* the endomorphism of $\mathscr{F}_{\bar{x}}$ induced by $F_{(q^n)}^*$. Up to isomorphism, $(F_{\bar{x}}^*, \mathscr{F}_{\bar{x}})$ does not depend on the choice of $\bar{x}$. The trace, etc. of F_x^* is denoted by notation such as $\mathrm{tr}(F_x^*, \mathscr{F})$.

1.6 L-function

Let X_0 be a scheme of finite type over $\mathbb{F}_q$. Denote by $|X_0|$ the set of its closed points, and for $x \in |X_0|$ set $\deg(x) = [k(x), \mathbb{F}_p]$. If $\mathscr{F}_0$ is a $\mathbb{Q}_\ell$-sheaf on X_0 (for this notion, see below)—or a constructible flat sheaf of modules over a commutative Noetherian ring A—denote by $L(X_0, \mathscr{F}_0)$ the formal series with constant term 1, in $\mathbb{Q}_\ell[\![t]\!]$ or in $A[\![t]\!]$,

$$L(X_0, \mathscr{F}_0) = \prod_{x \in |X_0|} \det\left(1 - F_x^* t^{\deg(x)}, \mathscr{F}\right)^{-1}.$$

1.7 Remark

In definition (1.6), one has $\deg(x) = [k(x), \mathbb{F}_p]$ (absolute degree), and not $\deg(x) = [k(x), \mathbb{F}_q]$ (degree relative to $\mathbb{F}_q$). The effect is that $L(X_0, \mathscr{F}_0)$ depends only on the scheme X_0 and the sheaf $\mathscr{F}_0$, not on q and the structure morphism $X_0 \to \mathrm{Spec}(\mathbb{F}_q)$. The indeterminate t is an avatar of p^{-s}.

1.8 The Galois point of view

This subsection (n°) will not be used in the remainder of the report. For $\mathscr{F}_0$ an abelian sheaf on X_0, the Galois group $\mathrm{Gal}(\mathbb{F}/\mathbb{F}_q)$ acts on $\mathbb{F}$, and by transport of structure on $\mathrm{H}_c^i(X, \mathscr{F})$. In particular, the Frobenius substitution φ (1.1) induces an automorphism, also denoted by φ, of $\mathrm{H}_c^i(X, \mathscr{F})$. The Frobenius correspondence, on the other hand, defines an endomorphism F^* of $\mathrm{H}_c^i(X, \mathscr{F})$. One has

$$F^{*-1} = \varphi \qquad (\text{on } \mathrm{H}_c^i(X, \mathscr{F})). \tag{1.8.1}$$

To see this, apply (1.4) to the case where Y_0 is a point: $Y_0 = \mathrm{Spec}(\mathbb{F}_q)$. One finds that $\mathrm{H}_c^i(X, \mathscr{F})$ is the fiber, at the geometric point $\mathrm{Spec}(\mathbb{F})$ of Y_0, of $\mathsf{R}^i f_! \mathscr{F}_0$, and that F^* is the fiber of the Frobenius correspondence of $\mathsf{R}^i f_! \mathscr{F}_0$. Let $[\mathsf{R}^i f_! \mathscr{F}_0]$ be as in (1.2). One has $\mathrm{H}_c^i(X, \mathscr{F}) = [\mathsf{R}^i f_! \mathscr{F}_0](\mathbb{F})$ and

a) φ acts by transport of structure, via its action on $\mathbb{F}$;

b) F^* is the inverse of $F : [\mathsf{R}^i f_! \mathscr{F}_0](\mathbb{F}) \to [\mathsf{R}^i f_! \mathscr{F}_0](\mathbb{F})$.

The conclusion follows from the identity $F = \varphi$ of (1.1).

One advantage of the Galois point of view is that it permits reasoning by transport of structure.

2 $\mathbb{Q}_\ell$-sheaves

The notion of $\mathbb{Q}_\ell$-sheaves is developed in detail in [21, V,VI]. We shall use only the definitions and results below.

Definition 2.1. *Let X be a Noetherian scheme. A $\mathbb{Z}_\ell$-sheaf $\mathscr{F}$ on X is an inverse system of sheaves $\mathscr{F}_n$ ($n \geqslant 0$), with $\mathscr{F}_n$ a constructible sheaf of $\mathbb{Z}/\ell^{n+1}$-modules [2, IX.2], such that the transition morphism $\mathscr{F}_n \to \mathscr{F}_{n-1}$ factors through an isomorphism*

$$\mathscr{F}_n \otimes_{\mathbb{Z}/\ell^{n+1}} \mathbb{Z}/\ell^n \xrightarrow{\sim} \mathscr{F}_{n-1}.$$

The sheaf $\mathscr{F}$ is said to be lisse *if the $\mathscr{F}_n$ are locally constant.*

The terminology of [21] is different: "constructible $\mathbb{Z}_\ell$-sheaf" is used there for "$\mathbb{Z}_\ell$-sheaf," and "constructibly twisted constant" for "lisse."

Likewise below, for $\mathbb{Q}_\ell$-sheaves.

2.2

If k is a separably closed field, a sheaf of $\mathbb{Z}/\ell^n$-modules on $\mathrm{Spec}(k)$ is identified with a $\mathbb{Z}/\ell^n$-module, and the functor $\mathscr{F} \mapsto \varprojlim \mathscr{F}_n$ identifies the $\mathbb{Z}_\ell$-sheaves on $\mathrm{Spec}(k)$ with the $\mathbb{Z}_\ell$-modules of finite type. This justifies the following definition: the *fiber* of the $\mathbb{Z}_\ell$-sheaf $\mathscr{F}$ at the geometric point x of X is the $\mathbb{Z}_\ell$-module $\varprojlim(\mathscr{F}_n)_x$.

2.3

Suppose X is connected, and let x be a geometric point of X. It is known that the "fiber at x" functor is an equivalence between the category of constructible locally constant sheaves of $\mathbb{Z}/\ell^n$-modules and the category of finite-type $\mathbb{Z}/\ell^n$-modules equipped with a continuous action of $\pi_1(X,x)$. Passing to the limit gives the following proposition.

Proposition 2.4. *Under the hypotheses above, the "fiber at x" functor is an equivalence between the category of lisse $\mathbb{Z}_\ell$-sheaves on X and that of finite-type $\mathbb{Z}_\ell$-modules equipped with a continuous action of $\pi_1(X,x)$.*

Proposition 2.5. *Let $\mathscr{F}$ be a $\mathbb{Z}_\ell$-sheaf on a Noetherian scheme X. There is a finite partition of X into locally closed parts X_i such that the $\mathscr{F}|X_i$ are lisse.*

Set $\mathrm{gr}_\ell^n \mathscr{F} = \ell^n \mathscr{F}_m / \ell^{m+1}\mathscr{F}_m$ for $m \geqslant n$, and $\mathrm{gr}_\ell \mathscr{F} = \bigoplus \mathrm{gr}_\ell^n \mathscr{F}$. It is a sheaf of modules over the Noetherian ring $\mathrm{gr}_\ell \mathbb{Z} = \mathbb{Z}/\ell[t]$, the graded ring of $\mathbb{Z}$ for the ℓ-adic filtration. It is a quotient of $\mathrm{gr}_\ell^0 \mathscr{F} \otimes_{\mathbb{Z}/\ell} \mathbb{Z}/\ell[t]$, hence a constructible sheaf of $\mathrm{gr}_\ell \mathbb{Z}$-modules [2, IX.2]; and there is a finite partition of X into locally closed parts X_i such that $\mathrm{gr}_\ell \mathscr{F}|X_i$ is locally constant. Each of the sheaves $\mathrm{gr}_\ell^n \mathscr{F}|X_i$ is then locally constant, as are the $\mathscr{F}_m|X_i$, which are successive extensions of them.

2.6

If $\mathscr{F}$ and $\mathscr{G}$ are two $\mathbb{Z}_\ell$-sheaves on X, set $\hom(\mathscr{F},\mathscr{G}) = \varprojlim(\mathscr{F}_n, \mathscr{G}_n)$; this is a $\mathbb{Z}_\ell$-module. Since $\hom(\mathscr{F}_n,\mathscr{G}_n) = \hom(\mathscr{F}_m,\mathscr{G}_n)$ for $m \geqslant n$, one also has

$$\hom(\mathscr{F},\mathscr{G}) = \varprojlim_n \varinjlim_m \hom(\mathscr{F}_m,\mathscr{G}_n),$$

so that the functor $\mathscr{F} \mapsto \text{“}\varprojlim\text{”}\mathscr{F}_n$ is fully faithful from the category of $\mathbb{Z}_\ell$-sheaves to that of pro-sheaves on X (= pro-objects of the category of sheaves on X). We shall use it to identify $\mathbb{Z}_\ell$-sheaves with certain pro-sheaves (those such that every $\mathscr{F}_n = \mathscr{F}/\ell^{n+1}\mathscr{F}$ is a sheaf, and $\mathscr{F} \xrightarrow{\sim} \text{“}\varprojlim\text{”}\mathscr{F}_n$). It is easily verified that if $\mathscr{F} + \text{“}\varprojlim\text{”}\mathscr{F}_n$, with $\mathscr{F}_n$ a constructible sheaf of $\mathbb{Z}/\ell^n$-modules, then $\mathscr{F}$ is a $\mathbb{Z}_\ell$-sheaf if and only if the inverse systems (in n) $\mathscr{F}_n/\ell^{k+1}\mathscr{F}_n$ are essentially constant: the inverse system of $\mathscr{F}'_k = \varprojlim_n \mathscr{F}_n/\ell^{k+1}\mathscr{F}_n$ then satisfies the conditions of (2.1), and $\mathscr{F} = \text{“}\varprojlim\text{”}\mathscr{F}'_k$.

In what follows, we abandon the notation $\mathscr{F}_n$ of (2.1); if $\mathscr{F}$ is a $\mathbb{Z}_\ell$-sheaf, the sheaf $\mathscr{F}_n$ of (2.1) will be denoted by $\mathscr{F} \otimes \mathbb{Z}/\ell^{n+1}$.

2.7

In the abelian category of pro-sheaves, the subcategory of $\mathbb{Z}_\ell$-sheaves is stable under kernels, cokernels, and extensions. This is clear for cokernels. For kernels, if $f : \mathscr{F} \to \mathscr{G}$ is a morphism of $\mathbb{Z}_\ell$-sheaves, it follows readily from (2.4, 2.5) and Artin–Rees that the inverse system of $\ker(f : \mathscr{F} \otimes \mathbb{Z}/\ell^n \to \mathscr{G} \otimes \mathbb{Z}/\ell^n)$ satisfies the criterion given in (2.6) above. There is even an integer r such that for every n

$$\ker(f) \otimes \mathbb{Z}/\ell^n = \ker(f : \mathscr{F} \otimes \mathbb{Z}/\ell^{n+r} \to \mathscr{G} \otimes \mathbb{Z}/\ell^{n+r}) \otimes \mathbb{Z}/\ell^n.$$

The case of extensions is left to the reader.

2.8

A $\mathbb{Z}_\ell$-sheaf $\mathscr{F}$ is *torsion-free* if $\ker(\ell : \mathscr{F} \to \mathscr{F}) = 0$. Each $\mathscr{F} \otimes \mathbb{Z}/\ell^n$ is then flat over $\mathbb{Z}/\ell^n$ (i.e. its fibers are finite-rank free $\mathbb{Z}/\ell^n$-modules). It follows from (2.4, 2.5) that for every $\mathbb{Z}_\ell$-sheaf $\mathscr{F}$ there is an integer n such that $\mathscr{F}/\ker(\ell^n)$ is torsion-free.

2.9

The abelian category of $\mathbb{Q}_\ell$-*sheaves* on X is the quotient of that of $\mathbb{Z}_\ell$-sheaves by the subcategory of torsion $\mathbb{Z}_\ell$-sheaves. Equivalently, its objects are the $\mathbb{Z}_\ell$-sheaves, and, denoting by $\mathscr{F} \otimes \mathbb{Z}_\ell$ the $\mathbb{Z}_\ell$-sheaf $\mathscr{F}$, viewed as an object of the category of $\mathbb{Q}_\ell$-sheaves, one has

$$\hom(\mathscr{F} \otimes \mathbb{Q}_\ell, \mathscr{G} \otimes \mathbb{Q}_\ell) = \hom(\mathscr{F}, \mathscr{G}) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell.$$

The *fiber* of a $\mathbb{Q}_\ell$-sheaf $\mathscr{F} \otimes \mathbb{Q}_\ell$ at a geometric point x of X is the finite-dimensional $\mathbb{Q}_\ell$-vector space $\mathscr{F}_x \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$.

2.10

Let X be a separated scheme of finite type over an algebraically closed field k, and let $\mathscr{F}$ be a constructible $\mathbb{Q}_\ell$-sheaf on X. Let $\mathscr{F}'$ be a constructible $\mathbb{Z}_\ell$-sheaf such that $\mathscr{F} \sim \mathscr{F}' \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$. We shall see in (4.11) that

$$\left(\varprojlim \mathrm{H}^q_c(X, \mathscr{F}' \otimes \mathbb{Z}/\ell^n)\right) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$$

is a finite-dimensional $\mathbb{Q}_\ell$-vector space. It depends only on $\mathscr{F}'$, and is denoted by $\mathrm{H}^q_c(X, \mathscr{F})$. The proof does not use the fact that ℓ is prime to the characteristic, but only that case concerns us.

2.11

In this exposé, all important calculations will be carried out at the level of $\mathbb{Z}/\ell^n$-sheaves, with passage to $\mathbb{Q}_\ell$-sheaves taking place only at the very end. In practice, however, it is often convenient to work systematically with $\mathbb{Q}_\ell$-sheaves. In Exposés V and VI of [21], Jouanolou gives the formalism that makes this possible. One of the essential results (VI 2.2) is that if $f : X \to Y$ is a separated morphism of finite type of Noetherian schemes, and $\mathscr{F}$ a $\mathbb{Z}_\ell$-sheaf on Y, then, for every q, the pro-sheaf "$\varprojlim$"$\mathsf{R}^q f_!(\mathscr{F} \otimes \mathbb{Z}/\ell^n)$ is a $\mathbb{Z}_\ell$-sheaf on Y. He even proves a stronger regularity property (of Artin–Rees type) for the inverse system of the $\mathsf{R}^q f_!(\mathscr{F} \otimes \mathbb{Z}/\ell^n)$.

Jouanolou even works in a more general setting, encompassing the very useful case of E_λ-sheaves, for E_λ a finite extension of $\mathbb{Q}_\ell$. They are defined as the $\mathbb{Q}_\ell$-sheaves were, with $\mathbb{Q}_\ell$ replaced by E_λ, $\mathbb{Z}_\ell$ by the ring $\mathscr{O}_\lambda$ of the valuation λ, and $\mathbb{Z}/\ell^n$ by $\mathscr{O}_\lambda/\pi^n$, where π is a uniformizer. It would amount to the same thing to define an E_λ-sheaf as a $\mathbb{Q}_\ell$-sheaf $\mathscr{F}$ equipped with a homomorphism $E_\lambda \to \mathrm{End}(\mathscr{F})$.

3 Trace formula and L-functions

We use the notation of §1, and ℓ is a prime number $\neq p$.

Let X_0 be a separated scheme of finite type over $\mathbb{F}_q$ ($q = p^f$), and let $\mathscr{F}_0$ be a constructible $\mathbb{Q}_\ell$-sheaf on X_0. Grothendieck's cohomological interpretation of L-functions is the following theorem:

Theorem 3.1. $L(X_0, \mathscr{F}_0) = \prod_i \det\left(1 - F^* t^f, \mathrm{H}^i_c(X, \mathscr{F})\right)^{(-1)^{i+1}}$.

It is obtained as a consequence of the trace formula:

Theorem 3.2. *For every integer n, $\sum_{x \in X^{F^n}} \mathrm{tr}\,(F^{n*}, \mathscr{F}_x) = \sum_i (-1)^i \,\mathrm{tr}\left(F^{n*}, \mathrm{H}^i_c(X, \mathscr{F})\right)$.*

Let us briefly recall the classical method for deducing (3.1) from (3.2). Set $T = t^f$; both sides are formal series in T with constant term 1. Since $\mathbb{Q}_\ell$ has characteristic 0, it suffices to prove that the logarithmic derivatives $T\frac{d}{dT}\log$ of the two sides are equal.

To compute these logarithmic derivatives, we shall use the formula

$$T\frac{d}{dT}\log\det(1 - fT)^{-1} = \sum_{n>0} \mathrm{tr}(f^n)T^n,$$

whose proof (in a slightly more general setting) is recalled below. On the left-hand side, one finds

$$\begin{aligned} T\frac{d}{dT}\log L(X_0, \mathscr{F}_0) &= \sum_{x \in |X_0|} \sum_n [k(x) : \mathbb{F}_q]\,\mathrm{tr}\,(F^n_x, \mathscr{F})\, T^{n \cdot [k(x):\mathbb{F}_q]} \\ &= \sum_{n>0} T^n \sum_{x \in X^{F^n}} \mathrm{tr}\,(F^{n*}, \mathscr{F}_x) \end{aligned}$$

and on the right-hand side

$$\sum_{n>0} T^n \sum (-1)^i \,\mathrm{tr}\left(F^{n*}, \mathrm{H}^i_c(X, \mathscr{F})\right)\ ;$$

the terms are compared one by one.

Proposition 3.3. *Let A be a commutative ring, M a projective A-module of finite type, and f an endomorphism of M. For every invertible formal series Q, set $\frac{d}{dT}\log Q = Q^{-1}\frac{d}{dT}Q$. One has*

$$T\frac{d}{dT}\log\det(1 - fT)^{-1} = \sum_{n>0} \mathrm{tr}(f^n)T^n. \tag{3.3.1}$$

Let M' be an A-module such that $M \oplus M'$ is free of finite rank. Replacing (M, f) by $(M \oplus M', f \oplus 0)$ changes neither side of (3.3), and reduces us to the case where M is free. For $M = A^d$, (3.3.1) is an algebraic identity in the coefficients f_i^j of f. By the principle of extension of algebraic identities, it suffices to verify it for A an algebraically closed field of characteristic 0. Since both sides are additive in M in an extension $0 \to M' \to M \to M'' \to 0$, it even suffices to treat only the case where M has rank 1. If f is multiplication by a, (3.3.1) then reduces to the formula

$$T\frac{d}{dT}\log\left((1-aT)^{-1}\right) = \sum_{n>0} a^n T^n.$$

Corollary 3.4. *Let n be an integer, and let $f^{(n)}$ be the endomorphism $(x_1, \ldots, x_n) \mapsto (f(x_n), x_1, \ldots, x_{n-1})$ of M^n. One has*

$$\det(1 - fT^n) = \det(1 - f^{(n)}T). \tag{3.4.1}$$

Proceeding as in (3.3), we reduce to assuming that A has characteristic 0. It then suffices to verify that the logarithmic derivatives $-T\frac{d}{dT}\log$ of the two sides are equal.

$$-T\frac{d}{dT}\log\det(1-fT^n) = -nT^n\frac{d}{dT^n}\log\det(1-fT^n) = n\sum_{m>0}\operatorname{tr}(f^m)T^{nm},$$

$$-T\frac{d}{dT}\log\det\left(1-f^{(n)}T\right) = \sum_{m>0}\operatorname{tr}\left(f^{(n)m}\right)T^m,$$

and one observes that

$$\operatorname{tr}(f^{(n)m}) = 0 \qquad \text{if } n \nmid m$$
$$\operatorname{tr}(f^{(n)nm}) = n\operatorname{tr}(f^m).$$

3.5 Remark

For $A = \mathbb{Q}_\ell$, (3.4.1) is the special case $X_0 = \operatorname{Spec}(\mathbb{F}_{q^n})$ of (3.1). Using this identity, it is easy to verify directly that the right-hand side of (3.1) is independent of q and of the structure morphism $X_0 \to \operatorname{Spec}(\mathbb{F}_q)$.

3.6 Remark

If $j : X_0 \hookrightarrow \bar{X}_0$ is a compactification of X_0, one has $L(X_0, \mathscr{F}_0) = L(\bar{X}_0, j_!\mathscr{F}_0)$ and $\mathrm{H}^i_c(X, \mathscr{F}) = \mathrm{H}^i(\bar{X}, j_!\mathscr{F})$. This reduces (3.1) to the proper case, and explains the use of cohomology with proper support. For X proper, (3.2) has the form of a Lefschetz trace formula. Note that the local terms $\operatorname{tr}(F^{n*}, \mathscr{F}_x)$ $(x \in X^{F^n})$ depend only on the fiber of $\mathscr{F}$ at x and carry no multiplicity. For X and $\mathscr{F}$ smooth, this corresponds to the fact that the graph of F is transverse to the diagonal (since $dF = 0$).

3.7 Remark

If the formalism of $\mathbb{Q}_\ell$-sheaves is admitted (cf. 2.11; one needs the Leray spectral sequence and the base-change theorem for the higher direct images $\mathsf{R}^q f_!$), it is easy to reduce the proof of (3.1, 3.2) to the case where X_0 is a smooth curve and $\mathscr{F}_0$ is lisse. This is clearly explained in [22, §5] (for 3.1; 3.2 is treated in the same way).

3.8

There are two methods for proving (3.2).

Lefschetz–Verdier If X_0 is proper (cf. 3.6), the general Lefschetz–Verdier trace formula expresses the right-hand side of (3.2) as a sum of local terms, one for each point of X^{F^n}. In the original version of [21], this formula was proved only modulo resolution of singularities. The reader will find an unconditional proof in the definitive version. In the case of curves, to which one can reduce (3.7), all the ingredients of the proof were in fact already available.

To deduce (3.2) from the Lefschetz–Verdier formula, one must be able to compute its local terms. For a curve and the Frobenius endomorphism, this had been done by Artin and Verdier [40].

Nielson–Wecken A method inspired by the work of Nielsen and Wecken makes it possible to reduce (3.2) to a special case proved by Weil; this is what will be explained in the following sections.

4 Reduction to theorems in $\mathbb{Z}/\ell^n$-cohomology

We shall prove (3.2) by passage to the limit from an analogous theorem in $\mathbb{Z}/\ell^n$-cohomology. Its statement presents the following difficulty. Let X_0 be a separated scheme of finite type over $\mathbb{F}_q$, and let $\mathscr{F}_0$ be a flat constructible sheaf of $\mathbb{Z}/\ell^n$-modules. Its fibers are finite-rank free $\mathbb{Z}/\ell^n$-modules, and the left-hand side of (3.2) therefore makes sense (it is an element of $\mathbb{Z}/\ell^n$). The $\mathrm{H}^i_c(X, \mathscr{F})$, on the other hand, will not in general be free, so the right-hand side is not defined. Overcoming this difficulty is one of Grothendieck's essential uses of the theory of derived categories.

4.1

For the definition of the derived category $\mathsf{D}(\mathcal{A})$ of an abelian category $\mathcal{A}$, and that of the subcategories $\mathsf{D}^+(\mathcal{A})$, $\mathsf{D}^-(\mathcal{A})$, $\mathsf{D}^b(\mathcal{A})$, I refer to Verdier's text in this volume. For Λ a ring, write $\mathsf{D}(\Lambda)$ instead of D(category of left Λ-modules); for X a site, write $\mathsf{D}(X, \Lambda)$ instead of D(category of sheaves of left Λ-modules). Likewise for D^-, etc...

The sign R (resp. L) indicates a right-derived (resp. left-derived) functor. For example, $\overset{\mathsf{L}}{\otimes}$ denotes the derived functor of the tensor product: for K in $\mathsf{D}^-(\Lambda^\circ)$ and L in $\mathsf{D}^-(\Lambda)$ (Λ° the opposite ring of Λ), $K \overset{\mathsf{L}}{\otimes} L$ is computed as follows: take quasi-isomorphisms $K' \to K$, $L' \to L$, with K' and L bounded above and one of them having flat components, and take the simple complex $s(K' \otimes_\Lambda L)$ associated with the double complex $K' \otimes_\Lambda L'$.

4.2

Even to treat only the case of $\mathbb{Z}/\ell^n$-cohomology, we shall need the theory of traces of endomorphisms of modules over rings that are not necessarily commutative (finite-group algebras $\mathbb{Z}/\ell^n[G]$). These traces were introduced by Stallings and Hattori [3].

Let Λ be a ring (with identity, but not necessarily commutative). Denote by $\Lambda^\natural$ the quotient of the additive group of Λ by the subgroup generated by the commutators $ab - ba$. If f is an endomorphism of the free left Λ-module Λ^n, with matrix f_i^j, denote by $\mathrm{tr}(f)$ the image of $\sum f_i^f$ in $\Lambda^\natural$. If f and g are two homomorphisms $f : \Lambda^n \leftrightarrows \Lambda^m : g$, one immediately verifies that $\mathrm{tr}(fg) = \mathrm{tr}(gf)$.

Let f be an endomorphism of a projective Λ-module of finite type P. Write P as a direct factor of a free module Λ^n: this means choosing a module P' and an isomorphism $\alpha : P \oplus P' \xrightarrow{\sim} \Lambda^n$, or equivalently choosing a homomorphism $a : P \to \Lambda^n$ and a retraction $b : \Lambda^n \to P$ (take $P = \ker(b)$). Let $f' = \alpha(f \oplus 0)\alpha^{-1} = afb$. Set $\mathrm{tr}(f) = \mathrm{tr}(f')$. This element of $\Lambda^\natural$ depends only on f: if another choice

$c : P \leftrightarrows \Lambda^m : d$ is made, one has $a = a(dc)(ba)$, whence

$$\mathrm{tr}(afb) = \mathrm{tr}(adcbafb) = \mathrm{tr}(cbafbad) = \mathrm{tr}(cfd).$$

If f is an endomorphism of a $\mathbb{Z}/2$-graded projective Λ-module of finite type, with components $f_i^j : P^j \to P^i$, set

$$\mathrm{tr}(f) = \mathrm{tr}(f_0^0) - \mathrm{tr}(f_1^1).$$

If there is a risk of ambiguity, we shall instead write $\mathrm{tr}(f; P)$. If the homomorphisms $f : P \leftrightarrows Q : g$ are homogeneous, reduction to the free case immediately verifies that

$$\mathrm{tr}(fg) = \mathrm{tr}\left((-1)^{\deg f \deg g} gf\right). \tag{4.2.1}$$

If f is an endomorphism of a filtered $\mathbb{Z}/2$-graded Λ-module (P, F), with finite filtration compatible with the grading, and the $\mathrm{gr}_F^i(P)$ are projective of finite type, then P is projective of finite type, and

$$\mathrm{tr}(f; P) = \sum \mathrm{tr}\left(f; \mathrm{gr}_F^i(P)\right) \tag{4.2.2}$$

(split the filtration to reduce to the case of a direct sum).

4.3

A $\mathbb{Z}$-graded module will be regarded as $\mathbb{Z}/2$-graded by the parity of the degree. In particular, if f is an endomorphism of a bounded complex of projective Λ-modules of finite type, set

$$\mathrm{tr}(f) = \sum (-1)^i \mathrm{tr}(f^i). \tag{4.3.1}$$

By (4.2.1), if f is homotopic to zero, $\mathrm{tr}(f) = 0$:

$$f = dH + hD \to \mathrm{tr}(f) = 0. \tag{4.3.2}$$

Let $\mathsf{K}_{\mathrm{parf}}(\Lambda)$ be the category whose objects are bounded complexes of projective Λ-modules of finite type and whose arrows are morphisms of complexes taken up to homotopy. The functor $\mathsf{K}_{\mathrm{parf}}(\Lambda) \to \mathsf{D}(\Lambda)$ is fully faithful. Denote its essential image by $\mathsf{D}_{\mathrm{parf}}(\Lambda)$. Formulas (4.3.1) and (4.3.2) make it possible to define $\mathrm{tr}(f)$ for f an endomorphism of $K \in \mathrm{Ob}\, \mathsf{D}_{\mathrm{parf}}(\Lambda)$ (and this trace depends only on the isomorphism class of (K, f)).

4.4

Recall that the filtered derived category $\mathsf{DF}(\mathcal{A})$ of an abelian category $\mathcal{A}$ is the category obtained from that of complexes of objects of $\mathcal{A}$ with finite filtration by inverting the filtered quasi-isomorphisms (= morphisms of filtered complexes inducing a quasi-isomorphism on the associated graded). There are functors "underlying complex": $\mathsf{DF}(\mathcal{A}) \to \mathsf{D}(\mathcal{A}) : (K, F) \mapsto K$, and "$p$-th component of the associated graded": $\mathsf{DF}(\mathcal{A}) \to \mathsf{D}(\mathcal{A}) : (K, F) \mapsto \mathrm{gr}_F^p(K)$.

Let $\mathsf{KF}_{\mathrm{parf}}(\Lambda)$ be the category whose objects are bounded filtered complexes (K, F) with finite filtration, with the $\mathrm{gr}_F^p(K^q)$ projective of finite type, and whose arrows are filtration-preserving morphisms of complexes taken up to a filtration-preserving homotopy. The functor $\mathsf{KF}_{\mathrm{parf}}(\Lambda) \to \mathsf{DF}(\Lambda)$ is fully faithful; its essential image $\mathsf{DF}_{\mathrm{parf}}(\Lambda)$ is almost everywhere zero; if (K, F) is in $\mathsf{D}_{\mathrm{parf}}(\Lambda)$, then K is in $\mathsf{D}_{\mathrm{parf}}(\Lambda)$.

By (4.2.2), if f is an endomorphism of $(K, F) \in \mathrm{Ob}\, \mathsf{DF}_{\mathrm{parf}}(\Lambda)$, one has

$$\mathrm{tr}(f, K) = \sum_p \mathrm{tr}(f, \mathrm{gr}_F^p(K)). \tag{4.4.1}$$

4.5

Let Λ be a ring, and let $K \in \mathrm{Ob}\,\mathsf{D}^-(\Lambda)$. We say that K has tor-dimension $\leqslant r$ if, for every right Λ-module N, the hypertors $\mathrm{H}^i(N \overset{\mathsf{L}}{\otimes}_\Lambda K)$ vanish for $i < -r$. It is said to have finite tor-dimension if this condition holds for some r.

The same terminology is used for a complex of sheaves $K \in \mathrm{Ob}\,\mathsf{D}^-(X, \Lambda)$.

Lemma 4.5.1. *Let Λ be a left Noetherian ring, and let $K \in \mathrm{Ob}\,\mathsf{D}^-(\Lambda)$. Then K belongs to $\mathsf{DF}_{parf}(\Lambda)$ if and only if it has finite tor-dimension and the $\mathrm{H}^i(K)$ are of finite type.*

After replacing K by an isomorphic complex (in $\mathsf{D}^-(\Lambda)$), we may suppose that K is bounded above and has finite-rank free components (cf. 4.7 below). If K has tor-dimension $\leqslant r$, the $\mathrm{H}^i(K)$ vanish for $i < -r$, $K^{-r}/\operatorname{im}(d)$ admits the free resolution

$$(\cdots \to K^{-r-1} \to K^{-r}) \to K^{-r}/\operatorname{im}(d),$$

and for every right Λ-module N, $\mathrm{H}^{-r-k}(N \overset{\mathsf{L}}{\otimes}_\Lambda K) = \mathrm{H}^{-r-k}(N \otimes_\Lambda K) = \mathrm{Tor}_k(N, K^r/\operatorname{im} d)$ for $k \geqslant 1$.

By hypothesis, these groups vanish; the module $K^r/\operatorname{im} d$ is therefore flat and finitely presented, i.e. projective of finite type. The quotient

$$0 \to K^r/\operatorname{im}(d) \to K^{r+1} \to K^{r+2} \to \cdots$$

of K is quasi-isomorphic to K, and this shows that $K \in \mathrm{Ob}\,\mathsf{DF}_{\mathrm{parf}}(\Lambda)$.

Proposition–Definition 4.6. *Let X be a Noetherian scheme, and let Λ be a left Noetherian ring. Denote by $\mathsf{D}^b_{\mathrm{ctf}}(X, \Lambda)$ the subcategory of $\mathsf{D}^-(X, \Lambda)$ formed by the complexes $\mathscr{K}$ satisfying the following equivalent conditions:*

i) $\mathscr{K}$ is isomorphic (in $\mathsf{D}^-(X, \Lambda)$) to a bounded complex of flat constructible sheaves of Λ-modules.

ii) $\mathscr{K}$ has finite tor-dimension and the sheaves $\mathrm{H}^i(K)$ are constructible.

The same argument as in (4.5), starting from the following lemma.

Lemma 4.7. *If a complex $\mathscr{K}$ of sheaves of Λ-modules is such that the $\mathrm{H}^i(\mathscr{K})$ are constructible and vanish for large i, there is a quasi-isomorphism $\mathscr{K}' \to \mathscr{K}$, with $\mathscr{K}'$ bounded above and having flat constructible components.*

Construct $\mathscr{K}'$ by proceeding from right to left. For an m such that the $\mathrm{H}^i(\mathscr{K})$ $(i \geqslant m)$ vanish, take $\mathscr{K}'^i = 0$ for $i \geqslant m$. Next suppose that the $\mathscr{K}'^i$ have already been constructed for $i > n$:

$$\begin{array}{ccccccccc} \cdots & \longrightarrow & \mathscr{K}^{n-1} & \longrightarrow & \mathscr{K}^n & \longrightarrow & \mathscr{K}^{n+1} & \longrightarrow & \cdots \\ & & & & & & \uparrow & & \\ & & & & & & \mathscr{K}'^{n+1} & \longrightarrow & \cdots, \end{array}$$

with $\mathrm{H}^i(\mathscr{K}') \xrightarrow{\sim} \mathrm{H}^i(\mathscr{K})$ for $i > n+1$, and $\ker(d) \to \mathrm{H}^{n+1}(\mathscr{K})$ surjective in degree $n+1$. Define sheaves $\mathscr{A}$ and $\mathscr{B}$ by the Cartesian diagram

$$\begin{array}{ccccc} \mathscr{K}^n & \longrightarrow & \mathscr{K}^n/\operatorname{im}(d) & \longrightarrow & \ker(d) \\ \uparrow & & \uparrow & & \uparrow \\ \mathscr{A} & \xrightarrow{u} & \mathscr{B} & \longrightarrow & \ker(d). \end{array}$$

Then $\mathscr{B}$ is constructible, u is surjective, and to advance one step it suffices to construct K^n flat and constructible and $v : \mathscr{K}^n \to \mathscr{A}$ such that uv is surjective. The possibility of doing so is guaranteed by the following lemma.

Lemma 4.8. *Let $v : \mathscr{A} \to \mathscr{B}$ be an epimorphism of sheaves of Λ-modules, with $\mathscr{B}$ constructible. There is then $u : \mathscr{K} \to \mathscr{A}$, with $\mathscr{K}$ flat and constructible, such that vu is an epimorphism.*

The sheaf $\mathscr{A}$ is a quotient of a sum of sheaves of the form $\varphi_!\Lambda$, for $\varphi : U \to X$ étale. Since $\mathscr{B}$ is Noetherian ([2, IX.2.10]), a finite sum of these already maps onto $\mathscr{B}$, which proves the lemma.

Theorem 4.9. *Let $f : X \to Y$ be a separated morphism of finite type of Noetherian schemes. If $\mathscr{K} \in \mathrm{Ob}\,\mathsf{D}^b_{\mathrm{ctf}}(X, \Lambda)$, then $\mathsf{R}f_!\mathscr{K} \in \mathrm{Ob}\,\mathsf{D}^b_{\mathrm{ctf}}(Y, \Lambda)$.*

Recall that if $j : X \hookrightarrow \bar{X} \xrightarrow{\bar{f}} Y$ is a relative compactification of X/Y, then by definition $\mathsf{R}f_! = \mathsf{R}\bar{f}_* \circ j_!$, where $\mathsf{R}\bar{f}_*$ is the derived functor of $\bar{f}_*$. This formula reduces the proof of (4.9) to the case where f is proper. For f proper, f_* has finite cohomological dimension; this makes it possible to define $\mathsf{R}f_*$ on the entire derived category, and also as a functor

$$\mathsf{R}f_* : \mathsf{D}^-(X, \Lambda) \to \mathsf{D}^-(Y, \Lambda).$$

By composition, one likewise defines in general

$$\mathsf{R}f_! : \mathsf{D}^-(X, \Lambda) \to \mathsf{D}^-(Y, \Lambda).$$

For every right Λ-module N, one has (proof given below)

$$N \overset{\mathsf{L}}{\otimes} \mathsf{R}f_!\mathscr{K} \xrightarrow{\sim} \mathsf{R}f_!(N \overset{\mathsf{L}}{\otimes} \mathscr{K}). \tag{4.9.1}$$

Let us deduce (4.9) from (4.9.1).

a) The spectral sequence
$$E_2^{pq} = \mathsf{R}^p f_!\, \mathrm{H}^q(\mathscr{K}) \to \mathrm{H}^{p+q}\, \mathsf{R}f_!\mathscr{K}\,.$$
and the finiteness theorem for $\mathsf{R}f_!$ show that $\mathsf{R}f_!\mathscr{K} \in \mathrm{Ob}\,\mathsf{D}^b(X, \Lambda)$ and has constructible cohomology. It remains to prove finite tor-dimension (4.6).

b) If $\mathscr{K}$ has tor-dimension $\leqslant -r$, the same is true of $\mathsf{R}f_!\mathscr{K}$: one has $\mathrm{H}^i(N \overset{\mathsf{L}}{\otimes} \mathsf{R}f_!\mathscr{K}) = \mathrm{H}^i(\mathsf{R}f_!(N \overset{\mathsf{L}}{\otimes} \mathscr{K}))$, and in the spectral sequence above for $N \overset{\mathsf{L}}{\otimes} \mathscr{K}$, the E_2^{pq} vanish for $q < r - s$, hence a fortiori for $p + q < r$.

Let us prove (4.9.1), remaining at the level of complexes.

a) Using the defining formula $\mathsf{R}f_! = \mathsf{R}f_* \circ j_!$, we reduce to assuming that f is proper.

b) Represent $\mathscr{K}$ by a complex bounded above whose components are acyclic for $f_* : \mathsf{R}^p f_* \mathscr{K}^q = 0$ for $p > 0$. One then has $\mathsf{R}f_*K \sim f_*\mathscr{K}$. It is possible to work in this way with complexes bounded above only because f_* has finite cohomological dimension.

c) If L is a free right Λ-module, one has $\mathsf{R}^p f_*(L \otimes \mathscr{K}^q) = L \otimes \mathsf{R}^p f_* \mathscr{K}^q$: this is trivial when Λ is free of finite type, and the general case follows by passage to the limit. The sheaf $L \otimes \mathscr{K}^q$ is acyclic for f_*, and $f_*(L \otimes \mathscr{K}^q) = L \otimes f_*\mathscr{K}^q$.

d) Let $N_\bullet$ be a free resolution of N. One has $N \overset{\mathsf{L}}{\otimes} \mathscr{K} \sim s(N_\bullet \otimes \mathscr{K})$ (the simple complex associated with the double complex $N_\bullet \otimes \mathscr{K}$). By c),

$$\mathsf{R}f_*(N \overset{\mathsf{L}}{\otimes} \mathscr{K}) \sim \mathsf{R}f_*(s(N_\bullet \otimes \mathscr{K})) \sim f_*(s(N_\bullet \otimes \mathscr{K})) \sim s(N_\bullet \otimes f_*\mathscr{K}) \sim N \overset{\mathsf{L}}{\otimes} \mathsf{R}f_*\mathscr{K},$$

which is the asserted formula.

When Y is the spectrum of a separably closed field, the functor $\mathsf{R}f_!$ is identified with a functor denoted by $\mathsf{R}\Gamma_c : \mathsf{D}^b_{\mathrm{ctf}}(X, \Lambda) \to \mathsf{D}_{\mathrm{parf}}(\Lambda)$.

Theorem 4.10. *With the notation of §1, let X_0 be a separated scheme of finite type over $\mathbb{F}_q$, and let Λ be a Noetherian torsion ring annihilated by an integer prime to p. Let $\mathscr{K}_0 \in \mathrm{Ob}\, \mathsf{D}^b_{\mathrm{ctf}}(X_0, \Lambda)$. With the definition of traces in (4.3), one has for every N*

$$\sum_{x \in X^{F^n}} \mathrm{tr}\,(F^{n*}, \mathscr{K}_x) = \mathrm{tr}\,(F^{n*}, \mathsf{R}\Gamma_c(X, \mathscr{K}))\,.$$

In the remainder of this §, we shall deduce 3.2 from 4.10, and prove 2.10.

4.11 Proof of 2.10

Let X be a separated scheme of finite type over an algebraically closed field k, and let $\mathscr{G}$ be a $\mathbb{Q}_\ell$-sheaf on X. By 2.8, it can be written in the form $\mathscr{G} = \mathscr{F} \otimes \mathbb{Q}_\ell$, with $\mathscr{F}$ a torsion-free $\mathbb{Z}_\ell$-sheaf. Set

$$K_n = \mathsf{R}\Gamma_c(X, \mathscr{F} \otimes \mathbb{Z}/\ell^{n+1}) \in \mathsf{D}(\mathbb{Z}/\ell^{n+1}).$$

By 4.9, one has $K_n \in \mathrm{Ob}\, \mathsf{D}_{\mathrm{parf}}(\mathbb{Z}/\ell^{n+1})$, and it follows from (4.9.1) that the natural arrow

$$K_n \overset{\mathsf{L}}{\otimes}_{\mathbb{Z}/\ell^{n+1}} \mathbb{Z}/\ell^n \longrightarrow K_{n+1}, \tag{4.11.1}$$

is an isomorphism. The problem of defining this arrow is discussed in 4.12.

We may now invoke [21, XI.3.3] (p. 31, lines 1–2 from the end; this passage is independent of the rest of [21]) to realize each K_n by a bounded complex of finite-rank free $\mathbb{Z}/\ell^{n+1}$-modules, and the arrows (4.11.1) by *isomorphisms of complexes*

$$K_n \otimes \mathbb{Z}/\ell^n \xrightarrow{\sim} K_{n-1}.$$

Let K be the complex $\varprojlim K_n$. It is a bounded complex of free $\mathbb{Z}_\ell$-modules, and $K_n \simeq K \otimes_{\mathbb{Z}_\ell} \mathbb{Z}/\ell^{n+1}$. One has

$$\mathrm{H}^i(K) = \varprojlim \mathrm{H}^i(K_n),$$

(indeed, every inverse system of finite groups satisfies the Mittag–Leffler condition), and $\mathrm{H}^i(K)$ is a $\mathbb{Z}_\ell$-module of finite type. One has

$$\mathrm{H}^i_c(X, \mathscr{G}) = \left(\varprojlim \mathrm{H}^i(K_n)\right) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell:$$

this is a finite-dimensional $\mathbb{Q}_\ell$-vector space.

4.12 The arrow (4.11.1)

To *define* the arrow (4.11.1), one cannot proceed as in 4.9, i.e. resolve $\mathbb{Z}/\ell^n$ by a complex of free $\mathbb{Z}/\ell^{n+1}$-modules, since one wishes to construct an isomorphism in $\mathsf{D}_{\mathrm{parf}}(\mathbb{Z}/\ell^n)$. The desired arrow is a special case of the following scalar-extension arrow.

(*) Let $\Lambda \to \Lambda'$ be a homomorphism of Noetherian torsion rings. For X a separated scheme of finite type over an algebraically closed k, and $\mathscr{K} \in \mathrm{Ob}\,\mathsf{D}_{\mathrm{ctf}}(X, \Lambda)$, one has an isomorphism

$$\mathsf{R}\Gamma_c(X, \mathscr{K}) \overset{\mathsf{L}}{\otimes}_\Lambda \Lambda' \xrightarrow{\sim} \mathsf{R}\Gamma_c(X, \mathscr{K} \overset{\mathsf{L}}{\otimes}_\Lambda \Lambda').$$

More general arrows are constructed in [2, XVII 4.2.12]. The method is as follows:

a) The definition of $\mathsf{R}\Gamma_c$ and the formula $j_!(\mathscr{K} \otimes_\Lambda \Lambda') = (j_!\mathscr{K}) \otimes_\Lambda \Lambda'$ for an open immersion reduce us to the case where X is proper.

b) For X proper, one must replace $\mathscr{K}$ by a bounded complex whose components are acyclic for the functor Γ, and whose fiber at every geometric point (or merely every closed point) is homotopic to a complex of flat Λ-modules. For such a complex, one has $\Gamma(X, \mathscr{K}) \sim \mathsf{R}\Gamma(X, \mathscr{K})$ and $K \otimes_\Lambda \Lambda' \sim \mathscr{K} \overset{\mathsf{L}}{\otimes}_\Lambda \Lambda'$; the arrow (4.11.1) is defined as the composite

$$\mathsf{R}\Gamma(X, \mathscr{K}) \overset{\mathsf{L}}{\otimes}_\Lambda \Lambda' \to \Gamma(X, \mathscr{K}) \otimes_\Lambda \Lambda' \to \Gamma(X, \mathscr{K} \otimes_\Lambda \Lambda') \xleftarrow{\sim} \mathsf{R}\Gamma(X, \mathscr{K} \overset{\mathsf{L}}{\otimes}_\Lambda \Lambda').$$

c) It remains to show that $\mathscr{K}$ can be replaced by a complex of the desired kind [2, XVII.4.2.10]. First replace $\mathscr{K}$ by a bounded complex with flat components (4.6), then take a truncated canonical flasque resolution of it (this does not modify the homotopy type of the fiber complexes, and one truncates far enough for the acyclicity condition for Γ to hold (i.e. beyond the cohomological dimension of Γ)).

4.13 Proof of (3.2)

To simplify notation, we shall treat only the case $n = 1$ of (3.2). The general case follows by replacing F below by F^n.

Thus let X_0 be separated and of finite type over $\mathbb{F}_q$, and let $\mathscr{G}_0$ be a $\mathbb{Q}_\ell$-sheaf on X_0. One has $\mathscr{G}_0 = \mathscr{F}_0 \otimes \mathbb{Q}_\ell$, for a suitable torsion-free $\mathbb{Z}_\ell$-sheaf $\mathscr{F}_0$. Let $K_n = \mathsf{R}\Gamma_c(X, \mathscr{F} \otimes \mathbb{Z}/\ell^n)$. The Frobenius morphisms induce morphisms

$$F^* : K_n \to K_n \qquad (\text{in } \mathsf{D}_{\mathrm{parf}}(\mathbb{Z}/\ell^{n+1})),$$

which are deduced from one another via the isomorphisms (4.11.1).

As in (4.11), realize the K_n and the isomorphisms (4.11.1) at the level of complexes. The already cited passage [21, XV.3.3] makes it possible to realize the morphisms F^* by endomorphisms of complexes, again denoted by F^*, which reduce to one another. Again denote by F^* their inverse limit and the endomorphisms deduced from it. Since $\mathrm{H}^i_c(X, \mathscr{G}) = \mathrm{H}^i(K) \otimes \mathbb{Q}_\ell = \mathrm{H}^i(K \otimes \mathbb{Q}_\ell)$, one has (with the sign convention of (?.1)

$$\mathrm{tr}\,(F^*, \mathrm{H}^\bullet_c(X, \mathscr{G})) = \mathrm{tr}\,(F^*, K^\bullet \otimes \mathbb{Q}_\ell) = \varprojlim_n \mathrm{tr}\,(F^*, K_n^\bullet) = \varprojlim_n \mathrm{tr}\left(F^*, \mathsf{R}\Gamma_c(X, \mathscr{F} \otimes \mathbb{Z}/\ell^{n+1})\right).$$

Apply (4.10) to $\mathscr{F}_0 \otimes \mathbb{Z}/\ell^{n+1}$ (viewed as a complex concentrated in degree 0), for $\Lambda = \mathbb{Z}/\ell^{n+1}$. One finds that

$$\begin{aligned}\operatorname{tr}\left(F^*, \mathsf{R}\Gamma_c(X, \mathscr{F} \otimes \mathbb{Z}/\ell^{n+1})\right) &= \sum_{x \in X^F} \operatorname{tr}\left(F^*, \mathscr{F}_x \otimes \mathbb{Z}/\ell^{n+1}\right) \\ &= \sum_{x \in X^F} \operatorname{tr}\left(F^*, \mathscr{G}_x\right) \mod \ell^{n+1},\end{aligned}$$

and (3.2) follows by passage to the limit.

5 The Nielsen–Wecken method

In this chapter, we prove two special cases of (4.10). The general case will be considered in the next chapter.

Lemma 5.1. *Theorem (4.10) is true for X_0 of dimension 0.*

In dimension 0, formula (4.10) holds for every correspondence, and not only for the iterates of a Frobenius. It is a special case of the following statement (applied to $X(\mathbb{F})$, K, and the F^{*n}).

(*) Let X be a finite set, $F : X \to X$, $\mathscr{K} \in \operatorname{Ob} \mathsf{D}_{\mathrm{parf}}(X, \Lambda)$, and $F^* : F^*\mathscr{K} \to \mathscr{K}$. One has

$$\sum_{X^F} \operatorname{tr}\left(F^*, \mathscr{K}_x\right) = \operatorname{tr}\left(F^*, \Gamma(X, K)\right).$$

One has $\Gamma(X, \mathscr{K}) = \bigoplus_{x \in X} \mathscr{K}_x$, and the formula follows from the fact that for every morphism $u : \bigoplus_{x \in X} \mathscr{K}_x \to \bigoplus_{x \in X} \mathscr{K}_x$, with matrix u^y_x, one has $\operatorname{tr}(u) = \sum_{x \in X} \operatorname{tr}\left(u^x_x\right)$.

Lemma 5.2. *Let Λ be a Noetherian torsion ring annihilated by a power of the prime number $\ell \neq p$, let X_0 be a smooth projective connected curve over $\mathbb{F}_q$, let $j : U_0 \hookrightarrow X_0$ be a dense open subscheme of X_0, and let $\mathscr{G}_0$ be a locally constant sheaf of projective Λ-modules on U_0. One has*

$$\sum_{x \in U^F} \operatorname{tr}\left(F^*, \mathscr{G}_x\right) = \operatorname{tr}\left(F^*, \mathsf{R}\Gamma_c(U, \mathscr{G})\right).$$

More precisely, we shall deduce (5.2) from the following theorem.

Theorem 5.3. *Let X be a nonsingular projective curve over an algebraically closed field k, let f be an endomorphism of X with isolated fixed points, and let $v(f)$ be the number of fixed points of f, each counted with its multiplicity: $v(f)$ is the intersection number of the graph of f with the diagonal of $X \times X$. Then, for ℓ prime to the characteristic exponent of k, one has*

$$v(f) = \sum (-1)^i \operatorname{tr}\left(f^*, \mathrm{H}^i(X, \mathbb{Q}_\ell)\right).$$

This theorem is due to Weil ([41], n° 43, 66, and 68), and Weil's proof is reproduced in Lang [26] (VI §3 combined with VII §2, Th. 3). It can also be deduced from the formalism of the cohomology class associated with a cycle (The cohomology class associated with a cycle, 3.7).

Corollary 5.4. *Let $j : U \hookrightarrow X$ be a dense open subscheme of X, such that $f^{-1}(U) = U$. If the fixed points of f in $X \smallsetminus U$ have multiplicity one, then the number $v_U(f)$ of fixed points of f in U (each counted with its multiplicity) is*

$$v_U(f) = \sum (-1)^i \operatorname{tr}\left(f^*, \mathrm{H}^i_c(U, \mathbb{Q}_\ell)\right).$$

Let F be the finite set $X \smallsetminus U$. The cohomology exact sequence defined by the short exact sequence $0 \to j_!\mathbb{Q}_\ell \to \mathbb{Q}_\ell \to \mathbb{Q}_{\ell F} \to 0$,

$$\xrightarrow{\partial} \mathrm{H}^i_c(U, \mathbb{Q}_\ell) \longrightarrow \mathrm{H}^i(X, \mathbb{Q}_\ell) \longrightarrow \mathrm{H}^i(F, \mathbb{Q}_\ell) \xrightarrow{\partial}$$

gives, with the sign convention of (3.1),

$$\mathrm{tr}\,(f^*, \mathrm{H}^\bullet_c(U, \mathbb{Q}_\ell)) = \mathrm{tr}\,(f^*, \mathrm{H}^\bullet(X, \mathbb{Q}_\ell)) - \mathrm{tr}\,(f^*, \mathrm{H}^\bullet(F, \mathbb{Q}_\ell)) = v(f) - \mathrm{tr}(f^*, \mathbb{Q}_\ell^F).$$

The trace of f^* on $\mathbb{Q}_\ell^F$ is the number $v_F(f)$ of fixed points of f in F; the multiplicity-one hypothesis therefore ensures that

$$\mathrm{tr}\,(f^*, \mathrm{H}^\bullet_c(U, \mathbb{Q}_\ell)) = v_F(f) - v_U(f),$$

as promised.

The proof of (5.2) uses some lemmas concerning a special case of noncommutative traces (4.2), which we now develop. *For brevity, we shall say projective for projective of finite type.*

5.5

Let Λ be a ring, and let H be a finite group. The map $\sum a_h \cdot a \mapsto$ class of a_e, from the group algebra $\Lambda[H]$ to $\Lambda^\natural$, vanishes on the commutators $ab - ba$ of $\Lambda[H]$. It therefore factors through

$$\varepsilon : \Lambda[H]^\natural \to \Lambda^\natural.$$

If F is an endomorphism of a projective $\Lambda[H]$-module P, set

$$\mathrm{tr}^H_\Lambda(F) = \varepsilon\, \mathrm{tr}_{\Lambda[H]}(F)$$

where the trace of (4.2) appears on the right-hand side. To avoid ambiguity, we shall sometimes write this trace as $\mathrm{tr}^H_\Lambda(F, P)$.

Proposition 5.6. $\mathrm{tr}_\Lambda(F) = |H|\,\mathrm{tr}^H_\Lambda(F)$.

The formal properties of traces reduce us to treating only the case $P = \Lambda[H]$. The endomorphism F is then right multiplication by an element $\sum a_h \cdot h$ of $\Lambda[H]$, and $\mathrm{tr}_\Lambda(F) = |H| a_e$, $\mathrm{tr}^H_\Lambda(F) = a_e$.

5.7

Let A be a commutative ring, and let Λ be an A-algebra. Multiplication by an element of A passes to the quotient to define an A-module structure on $A^\natural$. If H is a finite group, P a projective $A[H]$-module, and M a $\Lambda[H]$-module projective as a Λ-module, it is known that the Λ-module $P \otimes_A H$, equipped with the diagonal action of H, is a projective $\Lambda[H]$-module. Indeed:

a) It suffices to verify this for $P = A[H]$.

b) The Λ-module $P \otimes_A M$, equipped with the action of H defined by its action on the first factor, is clearly a projective $\Lambda[H]$-module; denote it by $(P \otimes_A M)'$.

c) The map $h \otimes m \mapsto h \otimes h^{-1}m$ induces an isomorphism

$$A[H] \otimes_A M \xrightarrow{\sim} (A[H] \otimes_A M)'. \tag{5.7.1}$$

Proposition 5.8. *With the preceding notation, if u is an endomorphism of F and v an endomorphism of M, then*

$$\mathrm{tr}^H_\Lambda(u \otimes v) = \mathrm{tr}^H_A(u)\,\mathrm{tr}_\Lambda(v).$$

We reduce to assuming that $P = A[H]$; the endomorphism u is then right multiplication m_x by an element $x = \sum a_h h$ of $A[H]$. Isomorphism (5.7.1) takes $u \otimes v$ to $\sum a_h m_h \otimes h^{-1}v$, whose trace is $a_e \cdot \mathrm{tr}_\Lambda(v)$.

5.9

Let G be a group that is an extension of $\mathbb{Z}$ by a finite group H

$$1 \to H \to G \to \mathbb{Z} \to 1,$$

and let G^+ be the inverse image of $\mathbb{N}$. Let Λ be a ring, and let P be a $\Lambda[G^+]$-module projective as a $\Lambda[H]$-module. If $g \in G^+$, denote by Z_g the centralizer of g in H; multiplication by g is an endomorphism of P, viewed as a $\Lambda[Z_g]$-module. Since P is $\Lambda[Z_g]$-projective, a trace $\mathrm{tr}_\Lambda^{Z_g}(g)$ is defined. By 5.6, one has

$$\mathrm{tr}_\Lambda(g) = |Z_g| \cdot \mathrm{tr}_\Lambda^{Z_g}(g). \tag{5.9.1}$$

Suppose that Λ is an algebra over a commutative ring A. For P an $A[G^+]$-module projective as an $A[H]$-module, and M a $\Lambda[G^+]$-module projective as a Λ-module, the $\Lambda[G^+]$-module $P \otimes_A M$ (diagonal action of G^+) is projective as a $\Lambda[H]$-module and, by 5.8, for every $g \in G^+$ one has

$$\mathrm{tr}_\Lambda^{Z_g}(g, P \otimes_A M) = \mathrm{tr}_A^{Z_g}(g, P) \cdot \mathrm{tr}_\Lambda(g, M). \tag{5.9.2}$$

5.10

Let P be a $\Lambda[G^+]$-module projective as a $\Lambda[H]$-module, and let P_H be the coinvariants of H in P. This is a projective Λ-module. The action of $g \in G^+$ passes to the quotient and defines an endomorphism of P_H that depends only on the image of g in $\mathbb{N}$. We denote by F the action of the elements $g \in G^+$ with image 1.

Proposition 5.11. $\mathrm{tr}_\Lambda(F, P_H) = \sum'_{g \mapsto 1} \mathrm{tr}_\Lambda^{Z_g}(g, P)$, *where* $\sum'_{g\mapsto 1}$ *denotes a sum over the* H*-conjugacy classes of elements of* G^+ *with image* 1 *in* $\mathbb{N}$.

After multiplication by $|H|$, this formula can be verified as follows:

$$|H| \cdot \mathrm{tr}_\Lambda(F, P_H) = \mathrm{tr}_\Lambda\left(\sum_{g\mapsto 1} g, P\right) = \sum_{g\mapsto 1}{}' \frac{|H|}{|Z_g|} \mathrm{tr}_\Lambda(g, P) = \sum_{g\mapsto 1}{}' |H| \cdot \mathrm{tr}_\Lambda^{Z_g}(g, P).$$

Choose an element $g \in G^+$ with image 1 in $\mathbb{N}$, and let σ be the automorphism of $\Lambda[H]$ induced by the automorphism $\mathrm{ad}\, g$ of H. Giving a $\Lambda[G^+]$-module amounts to giving a $\Lambda[H]$–module equipped with a σ-linear endomorphism γ: let $g^n h$ act by $\gamma^n h$. In this language, formula 5.11 takes the form: for P a projective $\Lambda[H]$-module and γ a σ-linear endomorphism of P, one has

$$\mathrm{tr}_\Lambda(\gamma, P_H) = \sum_h{}' \mathrm{tr}_\Lambda^{Z_g}(h\gamma, P),$$

where $\sum'$ is a sum over the $\mathrm{ad}\, g$-conjugacy classes in H (orbits of H acting on itself by the maps $x \mapsto hx\, \mathrm{ad}\, g(h)^{-1}$).

In this form, the properties of traces immediately reduce us to the case $P = \Lambda[H]$. The endomorphism Y then has the form $x \mapsto \sigma(x)a$, with $a = \sum a_h h$ in $\Lambda[H]$. It suffices to treat the universal case where the a_h are indeterminates. In this case, $\Lambda = \mathbb{Z}\langle a_h\rangle_{h\in H}$ (noncommutative polynomials), and $\Lambda^\natural$ is torsion-free: one obtains 5.11 by the argument at the beginning and division by $|H|$. One can also calculate directly.

5.11.1 Remark

Everything said above applies equally well to $\mathbb{Z}/2$-graded modules, or to complexes of modules (cf. 4.2, 4.3).

5.12

Retain the notation of 5.2, and let $A = \mathbb{Z}/\ell^n$, with n large enough that Λ is an A-algebra. Let $f : V_0 \to U_0$ be a finite étale connected covering of U_0, Galois with Galois group H, and such that the sheaf $f^*\mathscr{G}_0$ is constant. Denote its constant value $\mathrm{H}^0(V_0, f^*\mathscr{G}_0)$ by M; it is a $\Lambda[H]$-module projective as a Λ-module.

The sheaf f_*A on U_0, equipped with the natural action of H, is a locally free sheaf (of rank one) of $A[H]$-modules. The complex $\mathsf{R}\Gamma_c(U, f_*A)$ is therefore an object of $\mathsf{D}_{\mathrm{parf}}(A[H])$. It is equipped with a Frobenius endomorphism F^*.

For the natural action of H on $f_*f^*\mathscr{G}_0$, the trace morphism $f_*f^*\mathscr{G}_0 \to \mathscr{G}_0$ factors through an isomorphism

$$(f_*f^*\mathscr{G}_0)_H \to \mathscr{G}_0.$$

Moreover, one has $f_*f^*\mathscr{G}_0 = f_*A \otimes_A M$ (with diagonal action of H). The isomorphism

$$\mathscr{G}_0 \xleftarrow{\sim} (f_*A \otimes_A M)_H = (f_*A \otimes_A M) \otimes_{\Lambda[H]} \Lambda$$

derives (4.12) to an isomorphism

$$\mathsf{R}\Gamma_c(U, \mathscr{G}) \sim (\mathsf{R}\Gamma_c(U, f_*A) \otimes_A M) \otimes_{\Lambda[H]} \Lambda.$$

The endomorphism F^* of the left-hand side is deduced from the endomorphism F^* of $\mathsf{R}\Gamma_c(U, f_*A)$. The complex of $\Lambda[H]$-modules $\mathsf{R}\Gamma_c(U, f_*A)$, equipped with F^*, can be viewed as a complex of $\Lambda[G^+]$-modules, for $G^+ = H \times \mathbb{N}$. Formulas 5.10 and (5.9.2), amplified by 5.11.1, therefore give

$$\mathrm{tr}\,(F^*, \mathsf{R}\Gamma_c(U, \mathscr{G})) = \sum_h{}' \mathrm{tr}_A^{Z_g}\,(hF^*, \mathsf{R}\Gamma_c(U, f_*A)) \cdot \mathrm{tr}_\Lambda(h, M)$$

where $\sum'$ is a sum over the conjugacy classes in H. Moreover,

$$|Z_h| \cdot \mathrm{tr}_A^{Z_h}\,(hF^*, \mathsf{R}\Gamma_c(U, f_A)) = \mathrm{tr}_A\left((Fh^{-1})^*, \mathsf{R}\Gamma_c(V, A)\right).$$

This formula remains true for $A = \mathbb{Z}/\ell^m$, with m increasingly large. Passing to the limit, one finds that $\mathrm{tr}_A^{Z_g}\,(hF^*, \mathsf{R}\Gamma_c(U, f^*A))$ is equal to

$$\frac{1}{|Z_h|}\sum(-1)^i \,\mathrm{tr}\left((Fh^{-1})^*, \mathrm{H}_c^i(V, \mathbb{Q}_\ell)\right)$$

(an element of $\mathbb{Z}_\ell$), and

$$\mathrm{tr}\,(F^*, \mathsf{R}\Gamma_c(U, \mathscr{G})) = \sum_h{}' \frac{1}{|Z_h|}\,\mathrm{tr}\left((Fh^{-1})^*, \mathrm{H}_c^i(V, \mathbb{Q}_\ell)\right) \cdot \mathrm{tr}_\Lambda(h, M). \tag{5.12.1}$$

5.13

It remains to apply 5.4 (note that if $\bar{V}$ is the nonsingular projective completion of V, all the fixed points of Fh^{-1} have multiplicity one). This can be done without any calculation:

A. If $U^F = \varnothing$, $\mathrm{tr}\,(F^*, \mathsf{R}\Gamma_c(U, \mathscr{G})) = 0$.

Indeed, Fh^{-1} has no fixed point on V; 5.4 shows that $\sum(-1)^i \,\mathrm{tr}\left((Fh^{-1})^*, \mathrm{H}_c^i(V, \mathbb{Q}_\ell)\right) = 0$, and one applies (5.12.1).

B. In the general case, let $j : U' = U \smallsetminus U^F \hookrightarrow U$. The filtration $j_!j^*\mathscr{G}_0 \subset \mathscr{G}_0$ of $\mathscr{G}_0$ induces a filtration of $\mathsf{R}\Gamma_c(U, \mathscr{G})$ with successive quotients $\mathsf{R}\Gamma_c(U', \mathscr{G})$ and $\mathsf{R}\Gamma_c(U^F, \mathscr{G})$. By (4.4.1) and 5.1, one has

$$\operatorname{tr}(F^*, \mathsf{R}\Gamma_c(U, \mathscr{G})) = \operatorname{tr}(F^*, \mathsf{R}\Gamma_c(U', \mathscr{G})) + \sum_{x \in U^F} \operatorname{tr}(F^*, \mathscr{G}_x),$$

and, since ${U'}^F = 0$, the first term on the right-hand side is 0.

6 End of the proof of 4.10

Let us prove 4.10 under the additional hypotheses that the ring Λ is annihilated by a power of a prime number $\ell \neq p$, and that $n = 1$. The general case will follow: decompose Λ into its ℓ-primary components (with ℓ running through the prime numbers), and replace $\mathbb{F}_q$ by $\mathbb{F}_{q^n}$ and X_0 by $X_0 \otimes_{\mathbb{F}_q} \mathbb{F}_{q^n}$.

For X_0 separated and of finite type over $\mathbb{F}_q$, and $\mathscr{K}_0 \in \operatorname{Ob} \mathsf{D}_{\mathrm{ctf}}(X_0, \Lambda)$, set

$$T'(X_0, \mathscr{K}_0) = \sum_{x \in X^F} \operatorname{tr}(F^*, \mathscr{K}_x)$$

and

$$T''(X_0, \mathscr{K}_0) = \operatorname{tr}(F^*, \mathsf{R}\Gamma_c(X, \mathscr{K})).$$

We must prove the identity

$$(1; X_0, \mathscr{K}_0) \qquad T'(X_0, \mathscr{K}_0) = T''(X_0, \mathscr{K}_0).$$

We begin by observing that T' and T'' (denoted generically by T) obey the same formalism:

(A) If $j : U_0 \hookrightarrow X_0$ is an open subscheme of X_0, with closed complement Y_0, one has

$$T(X_0, \mathscr{K}_0) = T(U_0, \mathscr{K}_0|U_0) + T(Y_0, \mathscr{K}_0|Y_0).$$

This is clear for T'. For T'', observe that the filtration $0 \subset j_!j^*\mathscr{K}_0 \subset \mathscr{K}_0$ of $\mathscr{K}_0$ induces a filtration of $\mathsf{R}\Gamma_c(X, \mathscr{K})$ with successive quotients $\mathsf{R}\Gamma_c(U, \mathscr{K})$ and $\mathsf{R}\Gamma_c(Y, \mathscr{K})$, and invoke (4.4.1) (more precisely stated: $\mathscr{K}_0$, equipped with the said filtration, defines an object of $\mathsf{DF}(X, \Lambda)$; applying $\mathsf{R}\Gamma_c$ gives an object of $\mathsf{DF}_{\mathrm{parf}}(\Lambda)$ whose underlying object is $\mathsf{R}\Gamma_c(X, \mathscr{K})$ and whose associated graded is as stated).

(B) If $\mathscr{K}_0$ is a bounded complex with constructible flat components,

$$T(X_0, \mathscr{K}_0) = \sum (-1)^i T(X_0, \mathscr{K}^i).$$

This is clear for T'; for T'', apply the argument above to the stupid filtration of $\mathscr{K}_0$ to obtain

$$T''(X_0, \mathscr{K}_0) = \sum T''(X_0, \mathscr{K}_0^i[-i]) = \sum (-1)^i T''(X_0, \mathscr{K}_0^i).$$

(C) For a morphism $f : X_0 \to Y_0$, one has

$$T''(X_0, \mathscr{K}_0) = T''(Y_0, \mathsf{R}f_!\mathscr{K}_0)$$

and the same identity holds for T' if the fibers of f at the rational points of Y_0 satisfy $\big(1; f^{-1}(y), \mathscr{K}_0|f^{-1}(y)\big)$: use the fact that

$$T'(X_0, \mathscr{K}_0) = \sum_{y \in Y^F} T'\left(f^{-1}(y), \mathscr{K}_0|f^{-1}(y)\right)$$

and

$$\mathsf{R}\Gamma_c(Y, \mathsf{R}f_!\mathscr{K}) = \mathsf{R}\Gamma_c(X, \mathscr{K}).$$

Using this formalism and 4.7, the proof of 4.10 is reduced to the two special cases 5.1 and 5.2.

Chapter 3

L-functions modulo ℓ^n and modulo p

In this exposé, I prove a formula analogous to the main theorem of the report on the trace formula (this volume; cited as "Report" below) for a coefficient ring A that is torsion prime to p, or a field of characteristic p. Essential use will be made of [2, XVII 5.5].

1 Symmetric tensors

1.1

Let A be a commutative ring. For a list of properties of the functors $\Gamma^n : (A\text{-modules}) \to (A\text{-modules})$, I refer to [2, XVII 5.5.1 and 2]. We recall only that for M flat (in fact, only the case where M is projective of finite type concerns us), one has

$$\Gamma^n M = \left(M^{\otimes n}\right)^{S_n} \qquad \text{(symmetric tensors of degree } n\text{)}.$$

1.2

Let X be an S-scheme, let X^n/S be the n-th fiber power of X, and let π be the projection from X^n/S onto $(X^n/S)/S_n = \mathrm{Sym}^n_S(X)$ (assumed to exist). If $\mathscr{G}$ is a sheaf of A-modules on X, the external tensor product of n copies of $\mathscr{G}$, namely $\mathscr{G}^{\boxtimes n}$, is an S_n-equivariant sheaf on X^n/S. We shall have to use the *external* functor Γ^n of [2, XVII 5.5.7 to 9]. We recall only that for $\mathscr{G}$ a sheaf of flat A-modules (in fact, only the constructible flat case concerns us), one has

$$\Gamma^n_{\mathrm{ext}}(\mathscr{G}) = \left(\pi_* \mathscr{G}^{\boxtimes n}\right)^{S_n}.$$

Lemma 1.3. *For $S = \mathrm{Spec}(k)$, with k algebraically closed, X a finite disjoint union of copies of S, and G a flat sheaf of A-modules on X, one has*

$$\Gamma\left(\mathrm{Sym}^n_S(X), \Gamma_{ext}(\mathscr{G})\right) = \Gamma^n \Gamma(X, \mathscr{G})$$

Indeed,

$$\begin{aligned}\Gamma\left(\mathrm{Sym}^n_S(X), \Gamma^n_{\mathrm{ext}}(\mathscr{G})\right) &= \Gamma\left(\mathrm{Sym}^n_S(X), \pi_* \mathscr{G}^{\boxtimes n}\right)^{S_n} \\ &= \Gamma\left(X^n/S, \mathscr{G}^{\boxtimes n}\right)^{S_n} = \left(\Gamma(X, \mathscr{G})^{\otimes n}\right)^{S_n} = \Gamma^n \Gamma(X, \mathscr{G}).\end{aligned}$$

1.4

We shall have to use the derived functors of the nonadditive functors Γ^n and Γ^n_{ext}.

The theory of such derived functors is due to Dold and Puppe [17]. For more complete reminders than those given below, I refer to [2, XVII 5.5.3].

Let $\mathcal{A}$ be an abelian category (or even an additive category in which every idempotent endomorphism is the projection onto a direct factor). Denote by N the normalization functor: N : (cosimplicial complexes of objects of $\mathcal{A}$) $\to$ (differential complexes of objects of $\mathcal{A}$, with K^i for $i < 0$). It is an equivalence of categories. Like its inverse, it takes homotopic morphisms to homotopic morphisms. If Γ is a functor $\mathcal{A} \to \mathcal{B}$, and if K is a complex of objects of $\mathcal{A}$, in nonnegative degrees ($K^i = 0$ for $i < 0$), we set $TK = NTN^{-1}K$.

1.5 Example

If K is concentrated in M in degree 0, TK is concentrated in TM in degree 0.

1.6

If K is a bounded complex, in nonnegative degrees, of projective A-modules of finite type, the complex of A-modules $\Gamma^n K$ has the same properties.

Denote by $\mathsf{D}^{\geqslant 0}_{\text{parf}}(A)$ the subcategory of $\mathsf{D}_{\text{parf}}(A)$ (Report, 4.3) consisting of complexes of tor-dimension $\leqslant 0$. One sees that Γ^n induces a functor

$$\mathsf{L}\Gamma^n : \mathsf{D}^{\geqslant 0}_{\text{parf}}(A) \to \mathsf{D}^{\geqslant 0}_{\text{parf}}(A).$$

For the analogous, but more complicated, definition of $\mathsf{L}\Gamma^n_{\text{ext}}$, I refer to [2, XVII 5.5.14].

1.7

Let K be a bounded complex of projective A-modules of finite type, and let u be an endomorphism of K. We denote by $\det(1 - ut, K)$ the formal series with constant term 1

$$\det(1 - ut, K) = \prod_i \det(1 - ut, K^i)^{(-1)^i}.$$

The verification of the following properties is left to the reader.

1.7.1

Let F be a finite filtration stable under u, such that the $\mathrm{gr}^p_F(K^q)$ are projective of finite type. Then

$$\det(1 - ut, K) = \prod_p \det(1 - ut, \mathrm{gr}^p_F(K)).$$

1.7.2

If K is shifted q places to the left, one has

$$\det(1 - ut, K[q]) = \det(1 - ut, K)^{(-1)^q}.$$

Proposition 1.8. *Let u be an endomorphism of a bounded complex, in nonnegative degrees, of projective A-modules of finite type. One has*

$$\det(1-ut,K)^{-1}=\sum_n \mathrm{tr}(u,\Gamma^n K)t^n. \tag{1.8.1}$$

Denote the right-hand side of (1.8.1) by $D(u,K)$.

Lemma 1.9. *Let u be an endomorphism of a short exact sequence of bounded complexes in degrees $\geqslant 0$ of projective A-modules of finite type*

$$0\to K'\to K\to K''\to 0.$$

One has $D(u,K)=D(u,K')\cdot D(u,K'')$.

If $0\to M'\to M\to M''\to 0$ is a split short exact sequence of A-modules, $\Gamma^n M$ has a natural filtration whose successive quotients are the $\Gamma^i M'\otimes\Gamma^j M''$ $(i+j=n)$. Consequently, $\Gamma^n K$ has a natural filtration whose successive quotients are the complexes $N(N^{-1}\Gamma^i K'\otimes N^{-1}\Gamma^j K'')$ $(i+j=n)$, canonically homotopic to the simple complexes $s(\Gamma^i K'\otimes\Gamma^i K'')$ obtained from the double complexes $\Gamma^i K'\otimes\Gamma^i K''$, and

$$\mathrm{tr}(u,\Gamma^n K)=\sum_{i+j=n}\mathrm{tr}(u,\Gamma^i K')\cdot\mathrm{tr}(u,\Gamma^j K''),$$

whence the lemma. From 1.9, one obtains by induction.

Lemma 1.10. *Let F be a finite filtration of K stable under u, such that the $\mathrm{gr}_F^p(K^q)$ are projective of finite type. Then*

$$D(u,K)=\prod_p D\left(u,\mathrm{gr}_F^p(K)\right).$$

Lemma 1.11. *Let u be an endomorphism of a projective A-module of finite type M, and let $M[-q]$ be the complex concentrated in M in degree q. One has*

$$D\left(u,M[-q]\right)=\Big(\sum\mathrm{tr}(u,\Gamma^n M)t^n\Big)^{(-1)^q}\qquad (q\geqslant 0.)$$

By 1.5, this is true for $q=0$. Proceeding by induction, it remains to show that

$$D\left(u,M[-q]\right)\cdot D\left(u,M[-(q+1)]\right)=1.$$

This formula follows from 1.9, applied to the complex K concentrated in M in degrees q and $q+1$ (with $d=\mathrm{id}$), and to its stupid filtration:

$$(\cdots 0\to M\cdots)\to(\cdots M\to M)\to(\cdots M\to 0\to 0\cdots).$$

Indeed, K is homotopic to 0. In the derived category, one therefore has $\Gamma^n(K)=\Gamma^n(0)$: 0 for $n>0$ and A for $n=0$, and $D(u,K)=1$.

1.12

Let us prove 1.8. By 1.10, applied to the "stupid" filtration of K by the subcomplexes

$$0\to\cdots\to 0\to K^q\to K^{q+1}\to\cdots,$$

one has

$$D(u,K)=\prod_q D\left(u,K^q[-q]\right) =_{(1.10)} \prod_q \left(\sum \operatorname{tr}\left(u,\Gamma^n(K^q)\right)t^n\right)^{(-1)^q}.$$

It remains to prove that for u an endomorphism of a projective module of finite type M, one has

$$\det\left(1-ut,M\right)^{-1}=\sum \operatorname{tr}(u,\Gamma^n M)t^n. \tag{1.12.1}$$

If $u=0$, both sides are equal to 1. By adjoining to M a module N on which $u=0$, and applying 1.9, we reduce to the assumption that M is free. Choose a basis for it. It is then a matter of proving algebraic identities among the coordinates of u. The principle of extension of algebraic identities reduces us to assuming that A is an algebraically closed field. The module M then admits a filtration stable under u with successive quotients of rank 1, and 1.10 reduces us to the case where M has rank 1. Formula (1.12.1) then reduces to the identity

$$\frac{1}{1-at}=\sum a^n t^n.$$

Corollary 1.13. *Let u and u' be endomorphisms of bounded complexes K and K' of projective A-modules of finite type. If, in the derived category, K, equipped with u, is isomorphic to K', equipped with u', then*

$$\det(1-ut,K)=\det(1-u't,K').$$

Applying 1.7.2, we reduce to assuming that K and K' are in nonnegative degrees. One then observes that the right-hand side of 1.8 has the required invariance property.

1.14

This corollary makes it possible to define $\det(1-ut,K)$ for u an endomorphism of $K\in \operatorname{Ob}\mathsf{D}_{\mathrm{parf}}(A)$. This construction is ad hoc; in fact, for v an automorphism of $L\in\operatorname{Ob}\mathsf{D}_{\mathrm{parf}}(\Lambda)$, one can define $\det(v)\in\Lambda^\times$, and $\det(1-ut,K)$ is obtained by taking $v=1-ut$, $\Lambda=A[\![t]\!]$, and $L=K\otimes_A\Lambda$.

2 The theorem

2.1

We retain the notation of (Report, §1). For A a commutative Noetherian torsion ring, X_0 a separated scheme of finite type over $\mathbb{F}_q$, and $\mathscr{K}_0\in\operatorname{Ob}\mathsf{D}_{\mathrm{ctf}}(X_0;A)$, set

$$L(X_0,\mathscr{K}_0)=\prod_{x\in|X_0|}\det\left(1-F_x^* t^{\deg(x)},\mathscr{K}\right)^{-1}$$

(1.7, 1.13, and Report, 1.5, 1.6).

Theorem 2.2. *In each of the following two cases*

a) A is torsion prime to p;

b) A is reduced and of characteristic p

one has

$$L(X_0,\mathscr{K}_0)=\det\left(1-F^* t^f,\mathsf{R}\Gamma_c(X,\mathscr{K})\right)^{-1}. \tag{2.2.1}$$

2.3 Remark

In case a), the method of Report, §3 makes it possible to deduce from the trace formula (Report 4.10) that the logarithmic derivatives of the two sides of (2.2.1) are equal. Since the ring A is a torsion ring, this does not suffice to prove 2.2.

2.4 Remark

If A is a field, one has

$$L(X_0, \mathscr{K}_0) = \prod_i L\left(X_0, \underline{\mathrm{H}}^i(\mathscr{K}_0)\right)^{(-1)^i}$$

and the spectral sequence $E_2^{pq} = \mathrm{H}_c^p(X, \underline{\mathrm{H}}^q(\mathscr{K})) \Rightarrow \mathrm{H}_c^{p+q}(X, \mathscr{K})$ shows that

$$\begin{aligned}\det\left(1 - F^*t, \mathsf{R}\Gamma_c(X, \mathscr{K})\right) &= \prod_n \det\left(1 - F^*t^f, \mathrm{H}_c^n(X, \mathscr{K})\right)^{(-1)^n} \\ &= \prod_{p,q} \det\left(1 - F^*t, \mathrm{H}_c^p(X, \underline{\mathrm{H}}^q(\mathscr{K}))\right)^{(-1)^{p+1}}.\end{aligned}$$

This reduces 2.2 (for A a field) to the following special case.

2.4.1

If $\mathscr{G}_0$ is a constructible sheaf of A-vector spaces, one has

$$L(X_0, \mathscr{G}_0) = \prod_n \det\left(1 - F^*t^f, \mathrm{H}_c^n(X, \mathscr{G})\right)^{(-1)^{n+1}}.$$

2.5 Remark

It is easy to reduce case b) to the case where A is a field (or even a finite field) of characteristic p; cf. 4.2.

2.6 Remark

The special case of b) where $A = \mathbb{Z}/p$, and where X is reduced to the constant sheaf $\mathbb{Z}/p$ in degree 0,

$$Z(X_0, t) = \prod_{x \in |X_0|} \left(1 - t^{\deg(x)}\right)^{-1} \equiv \prod_n \det\left(1 - F^*t^f, \mathrm{H}_c^n(X, \mathbb{Z}/p)\right)^{(-1)^{n+1}} \pmod{p}$$

was proved by N. Katz [16, XXII 3.1]. His method, entirely different from the one followed here, starts from Dwork's p-adic theory of $Z(X_0, t)$.

2.7 Remark

Contrary to what I had rashly asserted to friends, in b) one cannot omit the hypothesis "A reduced." For a counterexample, cf. 4.5.

2.8 Outline of the proof of 2.2

A shift in degrees 1.7.2 reduces us to assuming that $\mathscr{K}_0$ is a bounded complex, in nonnegative degrees, of constructible flat sheaves of A-modules. One then has $\mathsf{R}\Gamma_c(X,\mathscr{K}) \in \mathrm{Ob}\,\mathsf{D}^{\geqslant 0}_{\mathrm{parf}}(A)$ (Report, proof of 4.9, b). We shall use 1.8 to expand both sides of (2.2.1) as power series in $T = t^f$. The equality of the coefficients of T^n will follow from [2, XVII 5.5.21] and a trace formula on $\mathrm{Sym}^n(X)$: in case a), the formula (Report, 4.10), and in case b), a formula to be proved in the next chapter. It is first necessary to reduce to the case where the symmetric powers of X_0 exist (for example, the case where X is affine), using the multiplicativity in X_0 of both sides of (2.2.1): for U_0 an open subscheme of X_0, with closed complement Y_0, one has $L(X_0,\mathscr{K}_0) = L(U_0,\mathscr{K}_0)\cdot L(Y_0,\mathscr{K}_0)$, and the analogous formula for the right-hand side follows from 1.7.1 by the method of (Report §6A).

2.9 The case where X_0 is finite

The multiplicativity in X_0 of both sides of (2.2.1) reduces this case to the case where $X_0 = \mathrm{Spec}(\mathbb{F}_{q^k})$. Returning to the definitions, one sees that (2.2.1) is then equivalent to Report 3.4.

2.10 The left-hand side

By 1.8, one has

$$L(X_0,\mathscr{K}_0) = \prod_{x\in|X_0|}\sum_n \mathrm{tr}\,(F_x^*,\Gamma^n\mathscr{K})\,t^{m\deg(x)}.$$

The coefficient of T^n is therefore the sum, over those formal linear combinations $\sum_{x\in|X_0|} n_x\cdot x$ ($n_x\geqslant 0$, with almost all the n_x zero) of elements of $|X_0|$ such that $\sum n_x[k(x):\mathbb{F}_q] = n$, of the products

$$\prod_x \mathrm{tr}\,(F_x^*,\Gamma^{n_x}\mathscr{K})\,. \tag{2.10.1}$$

For $x\in|X_0|$, denote by (x) the 0-cycle consisting of the $[k(x):\mathbb{F}_q]$ points of X above x (an orbit of F). The map $\sum n_x \mapsto \sum n_x\cdot(x)$ identifies the formal linear combinations above, with $\sum n_x[k(x):\mathbb{F}_q] = n$, with the effective 0-cycles of degree n on X fixed under F, or equivalently with the fixed points of F in $\mathrm{Sym}^n(X)$. The coefficient of T^n in $L(X_0,\mathscr{K}_0)$ thus appears as a sum of products (2.10.1), indexed by $\mathrm{Sym}^n(X)^F$. More precisely,

Lemma 2.11. $L(X_0,\mathscr{K}_0) = \sum_n \sum_{x\in\mathrm{Sym}^n(X)^F} \mathrm{tr}\,(F_x^*,\mathsf{L}\Gamma^n_{\mathrm{ext}}\mathscr{K})\,T^n$.

For Y_0 an increasingly large finite subscheme of X_0, one has

$$L(X_0,\mathscr{K}_0) = \lim L(Y_0,\mathscr{K}_0),$$

i.e., for every m, there is a finite subscheme $Z_0\subset X_0$ such that if $Y_0\supset Z_0$, then $L(X_0,\mathscr{K}_0)$ and $L(Y_0,\mathscr{K}_0|Y_0)$ are congruent $\mod T^m$. It suffices for Z_0 to contain the closed points of degree $\leqslant m$. Since the same fact holds for the right-hand side, it suffices to prove 2.11 for X_0 finite. One then has

$$\begin{aligned}
L(X_0,\mathscr{K}_0) &=_{2.9} \det\,(1-F^*T,\Gamma(X,\mathscr{K}))^{-1}\\
&=_{1.8} \sum_n \mathrm{tr}\,(F^*,\Gamma^n\Gamma(X,\mathscr{K}))\,T^n\\
&=_{1.3} \sum_n \mathrm{tr}\,(F^*,\Gamma(\mathrm{Sym}^n(X),\Gamma^n_{\mathrm{ext}}(\mathscr{K}))\,T^n\\
&= \sum_n \sum_{x\in\mathrm{Sym}^n(X)^F} \mathrm{tr}\,(F_x^*,\Gamma^n_{\mathrm{ext}}(\mathscr{K}))\,T^n
\end{aligned}$$

(by the trace formula in the trivial case of a finite set).

2.12 The right-hand side

By 1.8 and [2, XVII 5.5.12], one has

$$\begin{aligned}\det\left(1-F^*T,\mathsf{R}\Gamma_c(X,\mathscr{K})\right)^{-1} &= \sum_n \operatorname{tr}\left(F^*,\mathsf{L}\Gamma^n\mathsf{R}\Gamma_c(X,\mathscr{K})\right)T^n\\ &= \sum_n \operatorname{tr}\left(F^*,\mathsf{R}\Gamma_c(\operatorname{Sym}^n(X),\Gamma^n_{\mathrm{ext}}\mathscr{K})\right)T^n.\end{aligned}$$

2.13

The theorem is therefore equivalent to the trace formulas

$$\operatorname{tr}\left(F^*,\mathsf{R}\Gamma_c(\operatorname{Sym}^n(X,\Gamma^n_{\mathrm{ext}}\mathscr{K})\right) = \sum_{x\in\operatorname{Sym}^n(X)^F}\operatorname{tr}\left(F^*_x,\Gamma^n_{\mathrm{ext}}\mathscr{K}\right).$$

In case a), they follow from Report 4.10. The analogous formula in case b) will be proved in §4.

3 Artin–Schreier theory

3.1

In what follows, a coherent sheaf on a scheme S will always be regarded as a sheaf on $S_{\text{ét}}$. Let S be a scheme of characteristic $p>0$. If G is a locally constant sheaf of finite-rank $\mathbb{Z}/p$-vector spaces, $\mathscr{G}=G\otimes_{\mathbb{Z}/p}\mathscr{O}$ is a locally free coherent sheaf on S. We shall denote by Φ both the endomorphism $f\mapsto f^p$ of $\mathscr{O}$ and its tensor product with the identity of G: $\phi:\mathscr{G}\to\mathscr{G}$. Artin–Schreier theory [2, IX 3.5] asserts that the sequence

$$0\longrightarrow\mathbb{Z}/p\longrightarrow\mathscr{O}\xrightarrow{\Phi-1}\mathscr{O}\longrightarrow 0$$

is exact. Tensoring with G gives an exact sequence

$$0\longrightarrow G\longrightarrow\mathscr{G}\xrightarrow{\Phi-1}\mathscr{G}\longrightarrow 0$$

3.2

Suppose that S is an open subscheme of a Noetherian scheme $\bar S$. Let $j:S\hookrightarrow\bar S$ be the inclusion morphism, and let I be a sheaf of ideals defining the closed complement $\bar S\smallsetminus S$. We again denote by Φ the extension of Φ to $j_*\mathscr{G}$ by functoriality.

Lemma 3.3. *There exist coherent extensions $\bar{\mathscr{G}}\subset j_*\mathscr{G}$ of $\mathscr{G}$ such that*

$$\Phi(\bar{\mathscr{G}})\subset I\cdot\bar{\mathscr{G}}. \tag{3.3.1}$$

If $\bar{\mathscr{G}}$ is such an extension, the sequence

$$0\longrightarrow j_!G\longrightarrow\bar{\mathscr{G}}\xrightarrow{\Phi-1}\bar{\mathscr{G}}\longrightarrow 0 \tag{3.3.2}$$

is exact.

a) *Existence*: Let $\mathscr{G}' \subset j_*\mathscr{G}$ be a coherent extension of $\mathscr{G}$ to $\bar{S}$. For every n, one has $\Phi(I^n\mathscr{G}') \subset I^{p^n}\Phi(\mathscr{G}')$. Let n be large enough that $I^{n(p-1)-1}\Phi(\mathscr{G}') \subset \mathscr{G}'$, and set $\bar{\mathscr{G}} = I^n\mathscr{G}'$. One has $\Phi(\bar{\mathscr{G}}) \subset I^{pn}\Phi(\mathscr{G}') = I \cdot I^n \cdot I^{n(p-1)-1}\Phi(\mathscr{G}') \subset I \cdot I^n\mathscr{G}' = I\bar{\mathscr{G}}$.

b) *Kernel of* $\Phi - 1$: On S, the assertion follows from 3.1; it remains to verify that a section x of $\ker(\Phi - 1)$, on U étale over $\bar{S}$, vanishes in a neighborhood of the inverse image of $\bar{S} \smallsetminus S$. Indeed, since $x = \Phi(x)$, one has by (3.3.1) that $x \in I\bar{\mathscr{G}}$; moreover, $x \in I^n\bar{\mathscr{G}} \Rightarrow x = \Phi(x) \in \Phi(I^n\bar{\mathscr{G}}) \subset I^{np}\bar{\mathscr{G}}$, and x lies in every $I^n\bar{\mathscr{G}}$, hence is zero near $\bar{S} \smallsetminus S$.

c) *Surjectivity of* $\Phi - 1$: We may suppose $\bar{S}$ affine, and write $\mathscr{G}$ as a quotient of $\mathscr{O}^n$; Φ then lifts to a p-linear map $\widetilde{\Phi} : \mathscr{O}^n \to \mathscr{O}^n$, and it suffices to verify the surjectivity of $\widetilde{\Phi} - 1$:

$$\begin{array}{ccc} \mathscr{O}^n & \xrightarrow{\widetilde{\Phi}-1} & \mathscr{O}^n \\ \downarrow & & \downarrow \\ \mathscr{G} & \xrightarrow{\Phi-1} & \mathscr{G} \end{array}$$

The sheaf $\mathscr{O}^n$ is the sheaf of local sections of the group scheme $\mathbb{G}_a^n$, and $\widetilde{\Phi} - 1$ is induced by a homomorphism from $\mathbb{G}_a^n$ to $\mathbb{G}_a^n$. This homomorphism is étale. To verify that it is surjective, it suffices to check this after every base change $\mathrm{Spec}(k) \to \bar{S}$ (k algebraically closed), and over an algebraically closed k, every étale homomorphism between connected groups of the same dimension is surjective. Finally, an étale surjective morphism of $\bar{S}$-schemes induces an epimorphism between the corresponding sheaves on $\bar{S}_{\mathrm{et}}$.

3.4 Frobenius and Frobenius

The absolute Frobenius morphism $F_{\mathrm{abs}} : S \to S$ is the identity on the underlying topological space of S, and $f \mapsto f^p$ on the structure sheaf. For U/S étale, one has a canonical isomorphism $F_{\mathrm{abs}}^*U = U$: the diagram

$$\begin{array}{ccc} U & \xrightarrow{F_{\mathrm{abs}}} & S \\ \downarrow & & \downarrow \\ S & \xrightarrow{F_{\mathrm{abs}}} & S \end{array}$$

is Cartesian. The endomorphism of the ringed site $(\bar{S}_{\mathrm{et}}, \mathscr{O}) \to (\bar{S}_{\mathrm{et}}, \mathscr{O})$ defined by F_{abs} can therefore be described as follows:

$$F_{\mathrm{abs}}^* \text{ is the identity on } S_{\mathrm{et}}\text{; the homomorphism } F_{\mathrm{abs}}^*\mathscr{O} = \mathscr{O} \to \mathscr{O} \text{ is } \Phi.$$

With this description, for every étale sheaf $\mathscr{G}$ on S, the Frobenius correspondence $F_{\mathrm{abs}}^*\mathscr{G} \to \mathscr{G}$ is the identity.

Giving a p-linear morphism of quasi-coherent sheaves $u : \mathscr{M} \to \mathscr{N}$ on S is equivalent to giving a linear morphism $u' : F_{\mathrm{abs}}^*\mathscr{M} \to \mathscr{N}$. In particular, with the notation of 3.5, the homomorphism $\Phi : \mathscr{G} \to \mathscr{G}$ corresponds to $\Phi' : F_{\mathrm{abs}}^*\mathscr{G} \to \mathscr{G}$.

Lemma 3.5. *With the notation of 3.4, the diagram*

$$\begin{array}{ccc} F_{\mathrm{abs}}^*G & \longrightarrow & G \\ \downarrow & & \downarrow \\ F_{\mathrm{abs}}^*\mathscr{G} & \xrightarrow{\Phi'} & \mathscr{G} \end{array}$$

is commutative.

It suffices to verify this locally. We may therefore suppose G constant, in which case the lemma is evident.

The same theory applies to the powers of F_{abs}.

3.6

Suppose now that $\bar{S}$ is a scheme over $\mathbb{F}_q$ ($q = p^f$), and in accordance with the conventions of Report §1, write $S_0, \bar{S}_0, G_0, \mathscr{G}_0, \bar{\mathscr{G}}_0$ in place of $S, \ldots$. Lemma 3.5, for $F^F_{\mathrm{abs}} : S_0 \to S_0$, gives a commutative diagram

$$\begin{array}{ccc} F^*G_0 & \longrightarrow & G_0 \\ \downarrow & & \downarrow \\ F^*\mathscr{G}_0 & \xrightarrow{(\Phi^f)'} & \mathscr{G}_0 \end{array} \qquad \text{, and then} \qquad \begin{array}{ccc} F^*(j_!G_0) & \longrightarrow & j_!G_0 \\ \downarrow & & \downarrow \\ F^*\bar{\mathscr{G}}_0 & \xrightarrow{(\Phi^f)'} & \mathscr{G}_0 \end{array},$$

and then, by extension of scalars from $\mathbb{F}_q$ to $\mathbb{F}$ and passage to cohomology,

$$\begin{array}{ccc} F^*(j_!G) & \xrightarrow{F_*} & j_!G \\ \downarrow & & \downarrow \\ F^*\bar{\mathscr{G}} & \longrightarrow & \bar{\mathscr{G}} \end{array} \qquad \text{and} \qquad \begin{array}{ccc} \mathrm{H}^\bullet(\bar{S}, j_!G) & \xrightarrow{F^*} & \mathrm{H}^\bullet(\bar{S}, j_!G) \\ \downarrow & & \downarrow \\ \mathrm{H}^\bullet(\bar{S}, \bar{\mathscr{G}}) & \longrightarrow & \mathrm{H}^\bullet(\bar{S}, \bar{\mathscr{G}}) \end{array},$$

where the second row is obtained by extension of scalars from $\mathbb{F}_q$ to $\mathbb{F}$ of the $\mathbb{F}_q$-linear endomorphism Φ^f of $\mathrm{H}^\bullet(\bar{S}_0, \bar{G}_0)$.

Artin–Schreier theory provides a long exact sequence

$$\cdots \longrightarrow \mathrm{H}^i(\bar{S}, j_!G) \longrightarrow \mathrm{H}^i(\bar{S}, \bar{\mathscr{G}}) \xrightarrow{\Phi - 1} \mathrm{H}^i(\bar{S}, \bar{\mathscr{G}}) \longrightarrow \cdots$$

where Φ is the p-linear extension to $\mathrm{H}^\bullet(\bar{S}, \bar{\mathscr{G}}) = \mathrm{H}^\bullet(\bar{S}_0, \bar{\mathscr{G}}_0) \otimes_{\mathbb{F}_q} \mathbb{F}$ of the p-linear endomorphism Φ of $\mathrm{H}^\bullet(\bar{S}_0, \bar{\mathscr{G}}_0)$.

3.7

If $\bar{S}_0$ is proper over $\mathbb{F}_q$, the $\mathrm{H}^i(\bar{S}, \bar{\mathscr{G}})$ are finite-dimensional and $\Phi - 1$ is surjective (cf. 3.6b). Thus

$$\mathrm{H}^i_c(S, G) = \ker\left(\Phi - 1 : \mathrm{H}^i(\bar{S}, \bar{G}) \to \mathrm{H}^i(\bar{S}, \bar{\mathscr{G}})\right),$$

and F^* is induced by the $\mathbb{F}$-linear extension to $\mathrm{H}^i(\bar{S}, \bar{\mathscr{G}}) = \mathrm{H}^i(\bar{S}_0, \bar{\mathscr{G}}_0) \otimes_{\mathbb{F}_q} \mathbb{F}$ of the $\mathbb{F}_q$-linear endomorphism Φ^f of $\mathrm{H}^i(\bar{S}_0 m \bar{\mathscr{G}}_0)$.

Applying Lemma 3.8 below, one deduces the identity

$$\mathrm{tr}\left(F^*, \mathrm{H}^i_c(S, G)\right) = \mathrm{tr}\left(\Phi^f, \mathrm{H}^i(\bar{S}_0, \bar{\mathscr{G}}_0)\right). \tag{3.7.1}$$

Lemma 3.8. *Let Φ be a p-linear endomorphism of a vector space V over $\mathbb{F}_q$: $\phi(\lambda x) = \lambda^p \phi(x)$. Set $F = \Phi^f$ (F is linear), and again denote by Φ and F the respective p-linear extensions of Φ and F to $V \otimes_{\mathbb{F}_q} \mathbb{F}$. Then F stabilizes* $\ker(\Phi - 1) \subset V \otimes_{\mathbb{F}_q} \mathbb{F}$ *and*

$$\mathrm{tr}\left(F, \ker(\Phi - 1)\right) = \mathrm{tr}(F, V) = \mathrm{tr}\left(F, V \otimes_{\mathbb{F}_q} \mathbb{F}\right).$$

On $V \otimes_{\mathbb{F}_q} \mathbb{F}$, one has $F\Phi = \Phi F$: the p-linear endomorphism $F\Phi - \Phi F$ vanishes on V, hence everywhere. Write $V = V' + V''$, with F invertible on V' and nilpotent on V''. The theory of p-linear endomorphisms ensures that

$$\ker(\Phi - 1) \otimes_{\mathbb{F}_q} \mathbb{F} \xrightarrow{\sim} V' \otimes_{\mathbb{F}_q} \mathbb{F}.$$

Since $\mathrm{tr}(F, V'') = 0$, one therefore has

$$\begin{aligned} \mathrm{tr}\left(F, \ker(\Phi - 1)\right) &= \mathrm{tr}\left(F, \ker(\Phi - 1) \otimes_{\mathbb{F}_q} \mathbb{F}\right) = \mathrm{tr}\left(F, V' \otimes_{\mathbb{F}_q} \mathbb{F}\right) \\ &= \mathrm{tr}\left(F, V \otimes_{\mathbb{F}_q} \mathbb{F}\right) = \mathrm{tr}(F, V). \end{aligned}$$

4 Trace formula modulo p

Theorem 4.1. *Let X_0 be a separated scheme of finite type over $\mathbb{F}_q$, let A be a commutative reduced Noetherian ring of characteristic p, and let $\mathscr{K}_0 \in \mathrm{Ob}\,\mathsf{D}_{\mathrm{ctf}}(X_0, A)$. One has*

$$\sum_{x \in X^F} \mathrm{tr}\left(F_x^*, \mathscr{K}_x\right) = \mathrm{tr}\left(F^*, \mathsf{R}\Gamma_c(X, \mathscr{K})\right). \tag{4.1.1}$$

4.2 Reduction to the case where A is a finite field

A standard passage-to-the-limit argument reduces us to the case where A is of finite type over $\mathbb{Z}/p$. For every maximal ideal $\mathfrak{m}$ of A, the image of each side of (4.1.1) in $A/\mathfrak{m}$ is given by the same formula, with $\mathscr{K}_0$ replaced by $\mathscr{K}_0 \overset{\mathsf{L}}{\otimes}_A A/\mathfrak{m} \in \mathrm{Ob}\,\mathsf{D}_{\mathrm{ctf}}(X_0, A/\mathfrak{m})$ (for the right-hand side, cf. Report 4.12). Since the $A/\mathfrak{m}$ are finite, and the intersection of the maximal ideals of A is reduced to 0, one obtains the stated reduction.

4.3 Reduction to the case where $A = \mathbb{Z}/p$

Suppose that A is a finite field, and denote by $T'_A(\mathscr{K}_0)$ and $T''_A(\mathscr{K}_0)$ the two sides of (4.1.1). If, by restriction of scalars, $\mathscr{K}_0$ is regarded as a complex of sheaves of $\mathbb{Z}/p$-modules, one has

$$T'_{\mathbb{Z}/p}(\mathscr{K}_0) = \mathrm{tr}_{A/(\mathbb{Z}/p)}\, T'_A(\mathscr{K}_0)$$

and likewise for T''. If (4.1.1) holds for $A = \mathbb{Z}/p$, one therefore has

$$\mathrm{tr}_{A/(\mathbb{Z}/p)}\, T'_A(\mathscr{K}_0) = \mathrm{tr}_{A/(\mathbb{Z}/p)}\, T''_A(\mathscr{K}_0). \tag{4.3.1}$$

I claim that, for every $\lambda \in A$, one even has

$$\mathrm{tr}_{A/(\mathbb{Z}/p)}\left(\lambda \cdot T'_A(\mathscr{K}_0)\right) = \mathrm{tr}_{A/(\mathbb{Z}/p)}\left(\lambda \cdot T''_A(\mathscr{K}_0)\right), \tag{4.3.2}$$

and hence $T'_A(\mathscr{K}_0) = T''_A(\mathscr{K}_0)$. This is clear for $\lambda = 0$. For λ invertible, denote by $A(\lambda)$ the inverse image on X of the free rank-one sheaf of A-modules on $\mathrm{Spec}(\mathbb{F}_q)$ for which $F^* = \lambda$. Formula (4.3.2) is precisely (4.3.1) for $A(\lambda) \otimes_A \mathscr{K}_0$.

Theorem 4.4. *Let $\bar{S}_0$ be a smooth projective curve, let $j : S_0 \hookrightarrow \bar{S}_0$ be a dense open subscheme of $\bar{S}_0$, and let G_0 be a locally constant sheaf of finite-rank $\mathbb{Z}/p$-vector spaces on S_0. One has*

$$\sum_{x \in S^F} \mathrm{tr}\left(F_x^*, G_x\right) = \sum_i (-1)^i \,\mathrm{tr}\left(F^*, \mathrm{H}^i_c(S, G)\right). \tag{4.4.1}$$

Proof. Apply 3.3 to $(S_0, \bar{S}_0, G_0)$. The coherent extension $\bar{\mathscr{G}_0}$ of $\mathscr{G}_0$ whose existence is guaranteed by 3.3 is locally free because it is torsion-free (we have $\bar{\mathscr{G}_0} \subset j_*\mathscr{G}_0$) and $\bar{S}_0$ is regular of dimension one. The q-linear endomorphism Φ^f of $\bar{\mathscr{G}_0}$ can be interpreted as a morphism

$$u : F^*\bar{\mathscr{G}_0} \to \bar{\mathscr{G}_0}.$$

It factors through $I\bar{G}$, where I defines the closed subset $\bar{S} \smallsetminus S$. Let $v : j_!G_0 \to \bar{\mathscr{G}_0}$ be the unique extension of the natural map $G_0 \to \mathscr{G}_0 = G_0 \otimes_{\mathbb{Z}/p} \mathscr{O}$. The diagram

$$\begin{array}{ccc} F^*j_!G_0 & \xrightarrow{F^*} & j_!G_0 \\ \downarrow{\scriptstyle F^*v} & & \downarrow{\scriptstyle v} \\ F^*\bar{\mathscr{G}_0} & \xrightarrow{u} & \bar{\mathscr{G}_0} \end{array} \tag{4.4.2}$$

Finally, denote by uF^* the composite map

$$\mathrm{H}^\bullet(\bar{S}, \bar{\mathscr{G}}) \xrightarrow{F^*} \mathrm{H}^\bullet(\bar{S}, F^*\bar{\mathscr{G}}) \xrightarrow{u} \mathrm{H}^\bullet(\bar{S}, \bar{\mathscr{G}}),$$

one has by (3.7.1)

$$\mathrm{tr}\left(F^*, \mathrm{H}^i_c(S, G)\right) = \mathrm{tr}\left(uF^*, \mathrm{H}^i(\bar{S}, \bar{\mathscr{G}})\right). \tag{4.4.3}$$

For every closed point $i_x : x \hookrightarrow \bar{S}$ of $\bar{S}$, set $\bar{\mathscr{G}_x} = i_x^*\bar{\mathscr{G}}$. The Lefschetz trace formula in coherent cohomology ("Woodshole fixed point formula"), applied to F and u, says that

$$\sum_i (-1)^i \,\mathrm{tr}\left(u^*F^*, \mathrm{H}^i(\bar{S}, \bar{\mathscr{G}})\right) = \sum_{x \in \bar{S}^F} \frac{\mathrm{tr}(u_x, \mathscr{G}_x)}{\det(1 - dF_x)}. \tag{4.4.4}$$

On the right-hand side,

a) since $dF = 0$, the denominators are equal to 1;

b) for $x \in \bar{S}^F \smallsetminus S^F$, the endomorphism u_x of $\bar{\mathscr{G}_x}$ is zero, and therefore so is $\mathrm{tr}(u_x, \bar{\mathscr{G}_x})$;

c) for $x \in S^F$, (4.4.4) gives a contribution

$$\mathrm{tr}(u_x, \bar{\mathscr{G}_x}) = \mathrm{tr}(F_x^*, G_x).$$

Identity (4.4.1) therefore follows from (4.4.3) and (4.4.4).

□

4.5 A counterexample

An example shows that the hypothesis that A be reduced cannot be omitted from 4.1.

Let Y_0 be the elliptic curve over $\mathbb{F}_2$ for which the eigenvalues of Frobenius are $\pm\sqrt{-2}$. It has 3 rational points and is supersingular. The involution $\sigma : x \mapsto -x$ therefore has only one fixed point, the point 0. The quotient of Y_0 by σ is a projective line; the quotient of $Y_0 \smallsetminus 0$ by σ is therefore an affine line $\mathbb{F}_0^1$, and $Y_0 \smallsetminus 0$ is an unramified double covering of $\mathbb{F}_0^1$:

$$\pi : Y_0 \smallsetminus 0 \to \mathbb{A}_0^1 \qquad , \pi = \pi\sigma.$$

The sheaf $\pi_*\mathbb{Z}/2$ is a free module of rank one over the algebra A of the two-element group $\{1, \sigma\}$ over $\mathbb{Z}/2$. This algebra is isomorphic to the algebra of numbers over $\mathbb{Z}/2$.

The sheaf of A-modules $\pi_*\mathbb{Z}/2$ is our example:

a) One has $\mathrm{H}^\bullet_c(\mathbb{A}^1, \pi_*\mathbb{Z}/2) = \mathrm{H}^\bullet_c(Y \smallsetminus 0, \mathbb{Z}/2)$. Since Y_0 is supersingular, one has $\mathrm{H}^i(Y, \mathbb{Z}/2) = 0$ for $i > 0$, and the long exact sequence

$$\cdots \to \mathrm{H}^i_c(Y \smallsetminus 0, \mathbb{Z}/2) \to \mathrm{H}^i(Y, \mathbb{Z}/2) \to \mathrm{H}^i(\{0\}, \mathbb{Z}/2) \to \cdots$$

shows that $\mathrm{H}^\bullet_c(Y \smallsetminus 0, \mathbb{Z}/2) = 0$. Thus $\mathrm{H}^\bullet_c(\mathbb{A}^1, \pi_*\mathbb{Z}/2) = 0$ and

$$\mathrm{tr}_A\left(F^*, \mathsf{R}\Gamma_c(\mathbb{A}^1, \pi_*\mathbb{Z}/2)\right) = 0.$$

b) Since $Y_0 \smallsetminus 0$ has two rational points, at one of the rational points of $\mathbb{A}^0_1$, the Frobenius substitution is the identity, and at the other, it is σ. Thus

$$\sum_{x \in \mathbb{A}^1{}^F} \mathrm{tr}\left(F^*, \pi_*\mathbb{Z}/2\right) = 1 + \sigma,$$

and $1 + \sigma \neq 0$.

The equation of the covering π is $y^2 - y = x^3$.

Chapter 4

The cohomology class associated with a cycle

This exposé is inspired by notes of Grothendieck that formed a preliminary version of [21, IV]. It defines the cohomology class of a cycle X in a separated smooth scheme of finite type over a field, and proves that intersection corresponds to the cup product.

Chapter 1 contains some general formalities. In Chapter 2, the class of a cycle is defined in several situations more general than the one just mentioned. The principal compatibility not considered is that between the direct image of a cycle and the trace morphism in cohomology. In Chapter 3, this formalism is used to deduce the Lefschetz trace formula for an endomorphism with isolated fixed points of a proper smooth scheme over an algebraically closed k—and for a Frobenius endomorphism of a curve.

We adopt the following conventions:

1) "scheme" means a separated Noetherian scheme (this is largely a hypothesis of convenience).

2) In Chapter 2, an integer n is fixed, and n is invertible on all schemes under consideration.

3) In Chapter 3, a prime number ℓ is fixed, and ℓ is invertible on all schemes under consideration. The cohomology used is always ℓ-adic cohomology:

$$\mathrm{H}^\bullet(X) = \mathbb{Q}_\ell \otimes_{\mathbb{Z}_\ell} \varprojlim \mathrm{H}^\bullet(X, \mathbb{Z}/\ell^n).$$

Cohomology classes of cycles, trace morphisms, ... are defined by passage to the limit from the case of finite coefficients $\mathbb{Z}/\ell^n$ (cf. [21, VI]).

1 Cohomology with support and cup products

This section contains reminders from general topology, which the reader is invited to consult only as the need arises.

by A. Grothendieck, written up by P. Deligne

1.1 H^1 and torsors

1.1.1

Let $\mathscr{F}$ be an abelian sheaf on a site X. It is known that $\mathrm{H}^1(X,\mathscr{F})$ classifies $\mathscr{F}$-torsors on X. We normalize (= choose the sign of) the isomorphism (set of isomorphism classes of F-torsors) $\to \mathrm{H}^1(X,\mathscr{F})$ in such a way that for every exact sequence $0 \to \mathscr{F} \xrightarrow{\alpha} \mathscr{G} \xrightarrow{\beta} \mathscr{H} \to 0$ and every $h \in \mathrm{H}^0(X,\mathscr{H})$, the $\mathscr{F}$-torsor $\beta^{-1}(h) \subset \mathscr{G}$, on which F acts by $(f,x) \mapsto \alpha(f)+x$, has class ∂h.

1.1.2

Let $\mathscr{P}$ be an $\mathscr{F}$-torsor. If (U_i) is an open covering of X, and p_i a section of $\mathscr{P}$ on U_i, one associates to $\mathscr{P}$ the Čech cocycle

$$p_{ij} = p_j - p_i \qquad (p_{ij} \in \mathrm{H}^0(U_i \times U_j, \mathscr{F})).$$

If, according to the usual rule, the map $\check{\mathrm{H}}^\bullet(X,\mathscr{F}) \to \mathrm{H}^\bullet(X,\mathscr{F})$ is defined so as to be a morphism of δ-functors, the image of $(p_{ij}) \in \check{\mathrm{H}}^1(X,\mathscr{F})$ in $\mathrm{H}^1(X,\mathscr{F})$ is the class of $\mathscr{P}$, normalized as in 1.1.1.

1.1.3

The definition of $\mathrm{H}^\bullet(X,\mathscr{F})$ is as follows: for $\mathscr{F}^\bullet$ a resolution of $\mathscr{F}$ with acyclic components, $\mathrm{H}^i(X,\mathscr{F}) = \mathrm{H}^i\,\Gamma(X,\mathscr{F}^\bullet)$. The δ-functor structure is obtained by associating to a short exact sequence of sheaves a short exact sequence of resolutions that remains exact after application of the functor Γ. If $\mathscr{F}^\bullet$ is a resolution of $\mathscr{F}$, the connecting homomorphism ∂ associated with

$$0 \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}^0 \xrightarrow{d} \ker(d) \longrightarrow 0$$

induces the negative of the defining isomorphism $\mathrm{H}^1(X,\mathscr{F}) = \Gamma\left(X,\ker(d)\right)/d\Gamma(X,\mathscr{F}^0)$.

1.1.4

Let U be an open part of X (a subsheaf of the final sheaf), and let D be the "closed complement." It is known that $\mathrm{H}^1_D(X,\mathscr{F})$ classifies the $\mathscr{F}$-torsors on X trivialized on U. For every short exact sequence $0 \to \mathscr{F} \xrightarrow{\alpha} \mathscr{G} \xrightarrow{\beta} \mathscr{H} \to 0$, and every section with support in D, $h \in \mathrm{H}^0_D(X,\mathscr{H})$, the torsor $\beta^{-1}(h)$, trivialized on U by the section 0, has class ∂h.

The long exact sequence of cohomology with support

$$\cdots \xrightarrow{\partial} \mathrm{H}^i_D(X,\mathscr{F}) \longrightarrow \mathrm{H}^i(X,\mathscr{F}) \longrightarrow \mathrm{H}^i(U,\mathscr{F}) \xrightarrow{\partial} \cdots$$

is defined from the sequence of functors

$$0 \longrightarrow \Gamma_D \longrightarrow \Gamma \longrightarrow \Gamma(U,-) \longrightarrow 0$$

(exact on injective sheaves). For every section $f \in \mathrm{H}^0(U,\mathscr{F})$, $\partial f \in \mathrm{H}^1_D(X,\mathscr{F})$ is the class of the trivial torsor $\mathscr{F}$, trivialized on U by the section f.

1.1.5

Let $j : U \hookrightarrow X$. If $\mathscr{F}$ injects into $j_*j^*\mathscr{F}$, the exact sequence

$$0 \longrightarrow \mathscr{F} \longrightarrow j_*j^*\mathscr{F} \longrightarrow j_*j^*\mathscr{F}/\mathscr{F} \longrightarrow 0$$

gives $\partial : \mathrm{H}^0(j_*j^*\mathscr{F}/\mathscr{F}) = \mathrm{H}^0_D(j_*j^*\mathscr{F}/\mathscr{F}) \to \mathrm{H}^1_D(X, \mathscr{F})$. The composite map

$$\mathrm{H}^0(U, \mathscr{F}) = \mathrm{H}^0(X, j_*j^*\mathscr{F}) \longrightarrow \mathrm{H}^0(X, j_*j^*\mathscr{F}/\mathscr{F}) \xrightarrow{\partial} \mathrm{H}^1_D(X, \mathscr{F})$$

is the negative of the map considered in 1.1.4.

1.1.6

Recall that if $\mathscr{L}$ is an invertible sheaf on a scheme X, the $\mathbb{G}_m$-torsor corresponding to it is the sheaf $\mathrm{Isom}(\mathscr{O}, \mathscr{L})$, on which $\mathbb{G}_m$ acts by $(\lambda, f) \mapsto f \circ (\lambda\cdot) = \lambda f$. Recall also that if D is a Cartier divisor on X, and $j : U \hookrightarrow X$ is the inclusion of the complementary open subscheme, the invertible sheaf $\mathscr{O}(D)$ is the subsheaf of $j_*\mathscr{O}_U$ consisting of local sections s such that sf lies in $\mathscr{O}_X$, where f is a local equation for D.

1.2 Cup products

In this subsection, we develop some observations about cup products in cohomology with support that will be used again in [Duality] to relate Poincaré duality for curves and self-duality of the Jacobian.

1.2.1

Let X be a site, Y a closed part of X, and $\mathscr{F}, \mathscr{G}$ two abelian sheaves on X. For example: X a scheme, Y a closed subscheme, and $\mathscr{F}, \mathscr{G}$ sheaves on X_{et}. Define a product

$$\Gamma_Y(X, \mathscr{F}) \otimes \Gamma(Y, \mathscr{G}) \to \Gamma_Y(X, \mathscr{F} \otimes \mathscr{G}). \tag{1.2.1.1}$$

The product of a section s of $\mathscr{F}$ with support in Y by a section t of $\mathscr{G}$ on Y is obtained as follows: locally on X, t is the restriction to Y of a section t' of $\mathscr{G}$ on X, and one forms the product $s \otimes t'$. It has support in Y and does not depend on the choice of t', which justifies the definition and permits it to be globalized.

Let $i : Y \hookrightarrow X$ be the inclusion morphism. The local analogue of (1.2.1.1) is the product

$$i^!\mathscr{F} \otimes i^*\mathscr{G} \to i^!(\mathscr{F} \otimes \mathscr{G}), \tag{1.2.1.2}$$

from which (1.2.1.1) follows by applying $\Gamma(Y, -)$.

1.2.2

Let us derive these arrows. Let $\mathscr{K}$, $\mathscr{L}$, and $\mathscr{M}$ be in the derived category, with a bilinear map $\mathscr{K} \overset{\mathsf{L}}{\otimes} \mathscr{L} \to \mathscr{M}$. Deriving (1.2.1.1) gives

$$\mathsf{R}\Gamma_Y(X, \mathscr{K}) \overset{\mathsf{L}}{\otimes} \mathsf{R}\Gamma(Y, \mathscr{L}) \to \mathsf{R}\Gamma_Y(X, \mathscr{M}) \tag{1.2.2.1}$$

inducing

$$\mathrm{H}^i_Y(X, \mathscr{K}) \otimes \mathrm{H}^j(Y, \mathscr{L}) \to \mathrm{H}^{i+j}_Y(X, \mathscr{M}) \tag{1.2.2.2}$$

(the cup product). The local arrow (1.2.1.2) gives

$$\mathsf{R}i^!\mathscr{K} \overset{\mathsf{L}}{\otimes} i^*\mathscr{L} \to \mathsf{R}i^!\mathscr{M}, \tag{1.2.2.3}$$

from which (1.2.2.1) follows by applying $\mathsf{R}\Gamma(Y, -)$.

1.2.3

Above, I passed over in silence the conflicts caused by using right-derived functors ($\mathsf{R}\Gamma$) and left-derived functors ($\overset{\mathsf{L}}{\otimes}$) in the same formula.

a) In the next subsection, all the right-derived functors under consideration will have finite cohomological dimension. This makes it possible to work systematically in the derived categories D^-. To have complexes that are both flat and flasque, one uses canonical flasque resolutions as in [2, XVII].

b) For a more general theory, one can no longer interpret bilinear maps from $\mathscr{K}$ and $\mathscr{L}$ to $\mathscr{M}$ as morphisms from $\mathscr{K}\overset{\mathsf{L}}{\otimes}\mathscr{L}$ to $\mathscr{M}$. For example, $\mathsf{R}\Gamma_Y(X,\mathscr{K})\overset{\mathsf{L}}{\otimes}\mathsf{R}\Gamma(Y,\mathscr{L})$ is not defined if both factors lie in D^+. One solution is to work in D^+, define

$$\mathrm{Bil}(\mathscr{K},\mathscr{L};\mathscr{M}) = \varinjlim \hom(\mathscr{K}'\otimes\mathscr{L}',\mathscr{M}'),$$

where the limit is taken over the quasi-isomorphisms $\mathscr{K}'\xrightarrow{\sim}\mathscr{K}$, $\mathscr{L}'\xrightarrow{\sim}\mathscr{L}$, $\mathscr{M}\xrightarrow{\sim}\mathscr{M}'$ ($\mathscr{K}'$, $\mathscr{L}'$, $\mathscr{M}'$ bounded below), where hom means "morphism of complexes, up to homotopy," and systematically use such bilinear maps without ever mentioning $\otimes$.

1.2.4 Second theme

Let U be an open subscheme of X, and let $j: U\hookrightarrow X$ be the inclusion morphism. For $\mathscr{K}$ in the derived category on U, set $\mathsf{R}\Gamma_!(U,\mathscr{K}) = \mathsf{R}\Gamma(X, j_!\mathscr{K})$. For $\mathscr{K}$, $\mathscr{L}$, and $\mathscr{M}$ on U, with a bilinear map $\mathscr{K}\overset{\mathsf{L}}{\otimes}\mathscr{L}\to\mathscr{M}$, we wish to define

$$\mathsf{R}\Gamma(U,\mathscr{K})\overset{\mathsf{L}}{\otimes}\mathsf{R}\Gamma_!(U,\mathscr{L})\to\mathsf{R}\Gamma_!(U,\mathscr{M}). \tag{1.2.4.1}$$

At the level of sheaves and their global sections, such a product follows from the isomorphism $j_*\mathscr{F}\otimes j_!\mathscr{G}\xleftarrow{\sim} j_!(\mathscr{F}\otimes\mathscr{G})$, but care must be taken because $\mathsf{R}\Gamma_!$ is not in general the derived functor of $\Gamma(X, j_!-)$.

We begin by defining

$$\mathsf{R}j_*\mathscr{K}\overset{\mathsf{L}}{\otimes}j_!\mathscr{L}\xleftarrow{\sim} j_!(\mathscr{K}\overset{\mathsf{L}}{\otimes}\mathscr{L})\longrightarrow j_!\mathscr{M}.$$

Applying $\mathsf{R}\Gamma(X,-)$ gives

$$\mathsf{R}\Gamma(U,\mathscr{K})\overset{\mathsf{L}}{\otimes}\mathsf{R}\Gamma_!(U,\mathscr{L}) = \mathsf{R}\Gamma(X,\mathsf{R}j_*\mathscr{K})\overset{\mathsf{L}}{\otimes}\mathsf{R}\Gamma(X,j_!\mathscr{L})\longrightarrow\mathsf{R}\Gamma(X,j_!\mathscr{M}).$$

Here again, the conflict between left and right will be resolved in the next subsection by working in D^-.

1.2.5 Coda

Let $j: U\hookrightarrow X$ be an open part, and let $i: Y\hookrightarrow U$ be a closed part of U. Let $\bar{Y}$ be a closed subset of X such that $\bar{Y}\cap U = Y$ (for example, the complement of $U\smallsetminus Y$). Let $\mathscr{K}$ be on U. Set $\mathsf{R}\Gamma_{Y!}(U,\mathscr{K}) = \mathsf{R}\Gamma_!(Y,\mathsf{R}i^!\mathscr{K})$, where $\mathsf{R}\Gamma_!$ is relative to the inclusion of Y into $\bar{Y}$. For every open subset V of U containing Y, $\mathsf{R}\Gamma_{Y!}(U,\mathscr{K})$ maps to $\mathsf{R}\Gamma_!(V,\mathscr{K})$: if i also denotes the inclusion of $\bar{Y}$ into X, j that of Y into $\bar{Y}$, and k that of V into X, one has $\mathsf{R}i^!\mathscr{K} = j^*\mathsf{R}i^!k_!(k^*\mathscr{K})$, whence a morphism $j_!\mathsf{R}i^!\mathscr{K}\to\mathsf{R}i^!k_!(k^*\mathscr{K})$. Applying $\mathsf{R}\Gamma(\bar{Y},-)$ to it gives $\mathsf{R}\Gamma_{Y!}(U,\mathscr{K})\to\mathsf{R}\Gamma_{\bar{Y}}(k_!k^*\mathscr{K})\to\mathsf{R}\Gamma(k_!k^*\mathscr{K}) = \mathsf{R}\Gamma_!(V,\mathscr{K})$.

For $\mathscr{K},\mathscr{L},\mathscr{M}$ on U, with a bilinear map $\mathscr{K}\overset{\mathsf{L}}{\otimes}\mathscr{L}\to\mathscr{M}$, we wish to define

$$\mathrm{H}^n(U,\mathscr{K})\otimes\mathrm{H}^m_!(Y,\mathscr{L})\to\mathrm{H}^{n+m}_{Y!}(U,\mathscr{M}) \tag{1.2.5.1}$$

(the last group itself mapping to $\mathrm{H}^{n+m}_!(V,\mathscr{M})$). In the derived category, this means defining

$$\mathsf{R}\Gamma_Y(U,\mathscr{K})\overset{\mathsf{L}}{\otimes}\mathsf{R}\Gamma_!(R,\mathscr{L})\to\mathsf{R}\Gamma_{Y!}(U,\mathscr{M}). \tag{1.2.5.2}$$

We identify $\mathsf{R}\Gamma_Y$ with $\mathsf{R}\Gamma(Y,\mathsf{R}i^!\mathscr{K})$. The desired product is then of type (1.2.4.1), relative to the local product (1.2.2.3) on Y: $\mathsf{R}i^!\mathscr{K}\overset{\mathsf{L}}{\otimes}\mathscr{L}\to\mathsf{R}i^!\mathscr{M}$.

1.2.6

Above, we developed the absolute formalism. There is a parallel relative formalism, with Γ replaced by f_* for f a morphism $X\to S$.

1.3 The Koszul rule

Let A be a commutative ring, and let $(V_i)_{i\in I}$ be a finite family of graded (or $\mathbb{Z}/2$-graded) A-modules. Recall the definition of the graded tensor product $\bigotimes_{i\in I}V_i$, in the sense of the Koszul rule (cf. [2, XVII 1.1]). For each total ordering a on I, we shall define a module $V(a)$. We shall also define a transitive system of isomorphisms $\varphi_{ab}:V(b)\xrightarrow{\sim}V(a)$, and the graded tensor product of the V_i will be the "common value" $\varprojlim V(a)$ of this system of modules. We take

a) $V(a)=\bigotimes_{i\in I}|V_i|$ (the ordinary tensor product of the underlying ungraded modules of the V_i).

b) if the $x_i\in V_i$ are homogeneous, we take $\varphi_{ab}(\otimes x_i)=(-1)^N\otimes x_i$, where N is the sum of the $\deg(x_i)\deg(x_j)$ over the pairs (i,j) such that $i<_a j$ and $i>_b j$.

Example 1

Take $I=\{1,2\}$, and let a be the ordering in which $1<2$, and b the ordering in which $1>2$. Let $v_i\in V_i$ be homogeneous, and denote by $v_1\otimes v_2$ (resp. $v_2\otimes v_1$) the image in the graded tensor product of the product of the v_i in $V(a)$ (resp. $V(b)$). One has

$$v_1\otimes v_2=(-1)^{\deg(v_1)\deg(v_2)}v_2\otimes v_1$$

(the Koszul rule).

Example 2

If all the V_i have degree 1, there is a canonical isomorphism relating the module underlying the graded tensor product and the ordinary tensor product of the modules $|V_i|$ underlying the V_i:

$$\Big|\bigotimes V_i\Big|\simeq\bigotimes|V_i|\otimes_{\mathbb{Z}}\bigwedge^{|I|}\mathbb{Z}^I.$$

Example 3

For A a field, and X_i a finite family of spaces, the Künneth formula is written $\mathrm{H}^\bullet(\prod X_i,A)=\bigotimes\mathrm{H}^\bullet(X_i,A)$.

Let $V^\vee$ be the graded dual of V. The canonical map

$$V^\vee\otimes V=V\otimes V^\vee\to A \tag{1.3.1}$$

is $v'\otimes v\to v'(v)$.

Suppose now that A is a field, and consider only finite-dimensional vector spaces. The canonical isomorphism

$$W \otimes V^\vee \to \hom(V, W) \tag{1.3.2}$$

is $w \otimes v' \mapsto (v \mapsto w \cdot v'(v))$. Via this isomorphism, the composition $\hom(Y,Z) \otimes \hom(X,Y) \to \hom(X,Z)$ is identified with the morphism induced by (1.3.1): $Z \otimes Y^\vee \otimes Y \otimes X^\vee \to Z \otimes X^\vee$.

The trace of $f : V \to V^\vee$ (zero for homogeneous f of degree $\neq 0$) is the image of f under

$$\mathrm{tr} : \hom(V,V) \xleftarrow[(1.3.2)]{\sim} V \otimes V^\vee = V^\vee \otimes V \to_{(1.3.1)} A. \tag{1.3.4}$$

It is easily verified that, for f of degree 0,

$$\mathrm{tr}(f, V) = \sum (-1)^i \,\mathrm{tr}(f, V^i). \tag{1.3.5}$$

Expressing the commutativity of the two morphisms obtained by composing the morphisms (1.3.1) $V^\vee \otimes V \otimes W^\vee \otimes W \to k$, one finds that for homogeneous $f : V \to W$ and $g : W \to V$, one has

$$\mathrm{tr}(fg) = (-1)^{\deg(f)\deg(g)} \,\mathrm{tr}(gf). \tag{1.3.6}$$

2 The cohomology class associated with a cycle

2.1 The class of a divisor

2.1.1

Let D be a Cartier divisor in a scheme X. Away from D, the invertible sheaf $\mathscr{O}(D)$ is trivialized by the section 1. The class $\mathrm{cl}(D)$ of D in $\mathrm{H}^1_D(X, \mathbb{G}_m)$ is the class of the corresponding $\mathbb{G}_m$-torsor trivialized on $X \smallsetminus D$ (1.1.6 and 1.1.4).

Let $\partial : \mathrm{H}^i(X \smallsetminus D, \mathbb{G}_m) \to \mathrm{H}^i_D(X, \mathbb{G}_m)$ be the morphism of 1.1.4. If D admits a global equation f, multiplication by f is an isomorphism from $\mathscr{O}(D)$, trivialized by 1 on $X \smallsetminus D$, to $\mathscr{O}$, trivialized by f on $X \smallsetminus D$. By 1.1.4, one therefore has

$$\mathrm{cl}(D) = \partial f. \tag{2.1.1}$$

For every morphism $u : X' \to X$ such that u^*D is again a Cartier divisor (i.e., $u^{-1}D$ is disjoint from $\mathrm{Ass}(X')$), one has $\mathrm{cl}(u^*D) = u^* \,\mathrm{cl}(D)$. If such functoriality were desired for every morphism u, one would have to consider not Cartier divisors, but more generally invertible sheaves equipped with a section.

Recall that the integer n is henceforth assumed invertible on the schemes under consideration. Let $\partial : \mathrm{H}^i_D(X, \mathbb{G}_m) \to \mathrm{H}^{i+1}_D(X, \boldsymbol{\mu}_n)$ be the boundary map for the Kummer exact sequence $0 \to \boldsymbol{\mu}_n \to \mathbb{G}_m \to \mathbb{G}_m \to 0$.

Definition 2.1.2. *The* class $\mathrm{cl}_n(D)$ *of* D *in* $\mathrm{H}^2_D(X, \boldsymbol{\mu}_n)$ *is* $\partial \,\mathrm{cl}(D)$.

When there is no risk of confusion, the subscript n will be omitted.

2.1.3

The diagram

$$\begin{array}{ccc} \mathrm{H}^0(X \smallsetminus D, \mathbb{G}_m) & \xrightarrow{\partial} & \mathrm{H}^1_D(X, \mathbb{G}_m) \\ \downarrow \partial & & \downarrow \partial \\ \mathrm{H}^1(X \smallsetminus D, \boldsymbol{\mu}_n) & \xrightarrow{\partial} & \mathrm{H}^2_D(X, \boldsymbol{\mu}_n) \end{array}$$

is anticommutative. If D admits a global equation f, $\mathrm{cl}_n(D)$ is therefore the negative of the image under ∂ of the class in $\mathrm{H}^1(X \smallsetminus D, \boldsymbol{\mu}_n)$ of the $\boldsymbol{\mu}_n$-torsor of n-th roots of f.

Proposition 2.1.4. *Let i be the inclusion of D into X. If D and X are regular, the cohomology sheaves with support $\mathsf{R}^p i^! \boldsymbol{\mu}_n$ are zero for $p = 0, 2$, and $\mathsf{R}^2 i^! \boldsymbol{\mu}_n = \underline{\mathbb{Z}/n}$, generated by $\mathrm{cl}_n(D)$.*

It suffices to prove that, for X strictly local and D defined by a regular parameter, one has $\mathrm{H}^p_D(X, d\mu_n) = 0$ for $p = 0, 1$ and $\mathrm{H}^2(X, \boldsymbol{\mu}_n) = \mathbb{Z}/n$, generated by $\mathrm{cl}(D)$. Denoting reduced cohomology by $\sim$, one has $\widetilde{\mathrm{H}}^{p-1}(X \smallsetminus D, \boldsymbol{\mu}_n) \xrightarrow{\sim} \mathrm{H}^p_D(X, \boldsymbol{\mu}_n)$. The assertion for $p = 0, 1$ says that D does not disconnect X, and for $p = 2$ it follows, via 2.1.3, from Abhyankar's lemma.

This is a partial analogue of the relative theorem (Étale cohomology, 5.3.4). Grothendieck conjectures that the $\mathsf{R}^p i^! \boldsymbol{\mu}_n$ vanish for $p \neq 2$, at least for X excellent (purity conjecture), but this is known only in characteristic 0 ([2, XIX]).

Theorem 2.1.5 (Fundamental compatibility)**.** *Let X be a smooth curve over an algebraically closed field k, let P be a closed point of X, and let* tr *be the composite $\mathrm{H}^2_P(X, \boldsymbol{\mu}_n) \to \mathrm{H}^2_c(X, \boldsymbol{\mu}_n) \xrightarrow{\mathrm{tr}} \mathbb{Z}/n$. One has*

$$\mathrm{tr}\, \mathrm{cl}(P) = 1.$$

Let $\bar{X}$ be the smooth projective curve completing X. The formula says that the invertible sheaf $\mathscr{O}(P)$ on $\bar{X}$ has degree 1.

2.2 Cohomological method

2.2.1

Let X be a (Noetherian) scheme. Recall that a subscheme Y of X is said to be a local complete intersection of codimension c if, locally (on Y), it is defined by a regular sequence of c equations in X. For X the spectrum of a local ring A with maximal ideal $\mathfrak{m}$, and Y with ideal $\mathfrak{a}$, this means that $\exp^i(A/\mathfrak{a}, A) = 0$ for $i < \dim(\mathfrak{a}/\mathfrak{m}\mathfrak{a}) = c$, and every sequence of elements of $\mathfrak{a}$ whose image in $\mathfrak{a}/\mathfrak{m}\mathfrak{a}$ is a basis of $\mathfrak{a}/\mathfrak{m}\mathfrak{a}$ is a regular sequence of equations for Y.

2.2.2

Let $i : Y \hookrightarrow X$ be a local complete intersection of codimension c. We propose to define a local fundamental class $\mathrm{cl}(Y)$ that is a global section of the cohomology sheaf with support $\mathsf{R}^{2c} i^! \mathbb{Z}/n(c)$ (recall that $\mathbb{Z}/n(c) = \boldsymbol{\mu}_n^{\otimes c}$).

Locally, Y is the intersection of a sequence of c divisors D_i, and we define $\mathrm{cl}(Y)$ as the cup product of the $\mathrm{cl}(D_i)$. Each $\mathrm{cl}(D_i)$ has support in D_i; their product has support in Y. The fact that this product is locally independent of the choice of the D_i follows from 2.2.3 below and the following invariance properties:

a) compatibility with localization;

b) independence of the ordering of the D_i (the $\mathrm{cl}(D_i)$ have degree 2, which is even, so the cup product is commutative);

c) the product depends only on the "flag" $D_1 \supset D_1 \cap D_2 \supset \cdots \supset Y$.

To prove c), note the existence of a product (a variant of 1.2.1)

$$\mathrm{H}^\bullet_{D_1}(X) \otimes \mathrm{H}^\bullet_{D_1 \cap D_2}(D_1) \otimes \cdots \otimes \mathrm{H}^\bullet_Y(D_1 \cap \cdots \cap D_{c-1}) \to \mathrm{H}^\bullet_Y(X);$$

the product of the $\mathrm{cl}(D_i)$ is also the product of the ($\mathrm{cl}(D_i)$ restricted to $D_1 \cap \cdots \cap D_{i-1}$) = ($\mathrm{cl}(D_1 \cap \cdots \cap D_i)$ in $D_1 \cap \cdots \cap D_{i-1}$).

Lemma 2.2.3. *Let A be a local ring with maximal ideal $\mathfrak{m}$, and let $u = (u_1, \ldots, u_c)$, $v = (v_1, \ldots, v_c)$ be two regular sequences generating the same ideal $\mathfrak{a}$. There is then a sequence w_i $(1 \leqslant i \leqslant N)$ of such sequences joining them, such that w_{i+1} is obtained from w_i by a permutation or by changing only the last element.*

Since permutations are available, it would amount to the same thing to allow one element, rather than the last element, to be changed. By 2.2.1, we are thus reduced to verifying that, in the vector space $\mathfrak{a}/\mathfrak{m}\mathfrak{a}$, one can pass from one basis to another by a sequence of permutations and changes of basis modifying only one vector. Indeed, the linear group is generated by diagonal, elementary, and permutation matrices.

2.2.4

The same methods make it possible to define a local fundamental class for every $Y \subset X$ locally definable by c equations (where fewer equations suffice, the class is zero).

2.2.5

One can pass from such a local fundamental class in $\mathrm{H}^0\left(Y, \mathsf{R}^{2c} i^! \mathbb{Z}/n(c)\right)$ to a global fundamental class in $\mathrm{H}^{2c}_Y(X, \mathbb{Z}/n(c))$ when semipurity results are available:

Proposition 2.2.6. *(i) If $\mathsf{R}^p i^! \mathbb{Z}/n = 0$ for $p < 2c$, then*

$$\mathrm{H}^{2c}_Y(X, \mathbb{Z}/n(c)) \xrightarrow{\sim} \mathrm{H}^0\left(Y, \mathsf{R}^{2c} i^! \mathbb{Z}/n(c)\right).$$

(ii) Let Z be a closed part of Y, with complement V in Y, and let k be the inclusion of Z into X. If $\mathsf{R}^p i^! \mathbb{Z}/n = 0$ for $p \leqslant 2c$, then

$$\mathrm{H}^{2c}_Y(X, \mathbb{Z}/n(c)) \hookrightarrow \mathrm{H}^{2c}_V(X, \mathbb{Z}/n(c)).$$

If $\mathsf{R}^p i^! \mathbb{Z}/n = 0$ for $p \leqslant 2c+1$, this arrow is an isomorphism.

The hypothesis $\mathsf{R}^p i^! \mathbb{Z}/n = 0$ is equivalent to $\mathsf{R}^p i^! \mathbb{Z}/n(c) = 0$. With this understood, (i) follows from the spectral sequence $\mathrm{H}^p(Y, \mathsf{R}^q i^!) \Rightarrow \mathrm{H}^{p+q}_Y(X, -)$. If k_1 is the inclusion of Z into Y, one has $k = ik_1$, whence $\mathsf{R}k^! \mathbb{Z}/n = \mathsf{R}k_1^! \mathsf{R}i^!$, and the long exact cohomology sequence for $Z \subset Y$ gives a long exact sequence

$$\cdots \longrightarrow \mathrm{H}^i\left(Z, \mathsf{R}k^! \mathbb{Z}/n(c)\right) \longrightarrow \mathrm{H}^i_Y(X, \mathbb{Z}/n(c)) \longrightarrow \mathrm{H}^i_V(X, \mathbb{Z}/n(c)) \longrightarrow \cdots$$

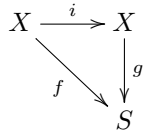
from which (ii) follows.

2.2.7 Amplification

Proposition 2.2.6 remains valid for i any separated morphism of finite type, and $2c$ any integer (positive or negative), provided that $\mathrm{H}^{2c}_Y(X, \mathbb{Z}/n(c))$ is replaced there by $\mathrm{H}^{2c}\left(Y, \mathsf{R}i^! \mathbb{Z}/n(c)\right)$, and likewise for H_V.

The following semipurity results follow from [24, 1.8, 1.10, 1.15]. We recall their proof.

Theorem 2.2.8. *Let there be a morphism of S-schemes of finite type*



Suppose that X is smooth, purely of relative dimension N, and that Y has fiberwise dimension $\leqslant d$. Let $c = N - d$.

(i) One has $\mathsf{R}^p i^!\mathbb{Z}/n = 0$ *for* $p < 2c$*; likewise with* $\mathbb{Z}/n$ *replaced by a sheaf* $g^*\mathscr{F}$*.*

(ii) If, over a dense open subset U *of* S*,* Y *has fiberwise dimension* $< d$*, one has* $\mathsf{R}^p i^!\mathbb{Z}/n = 0$ *for* $p \leqslant 2c$*. If in addition the complement* Z *of* U *does not locally disconnect* S*, one has* $\mathsf{R}^p i^!\mathbb{Z}/n = 0$ *for* $p \leqslant 2c+1$*.*

Since $\mathsf{R}g^!\mathscr{F} = g^*\mathscr{F}(N)[2N]$, the transitivity formula $\mathsf{R}i^!\mathsf{R}g^! = \mathsf{R}f^!$ shows that $\mathsf{R}^{2c+q}i^!(g^*\mathscr{F}) = 0 \Leftrightarrow \mathsf{R}^{-2d+q}f^!(\mathscr{F})$. This reduces us to studying f, i.e. to assuming that $X = S$. Assertion (i) is then [2, XVIII 3.17].

Let Y' be the inverse image of Z in Y:

$$\begin{array}{ccc} Y' & \xrightarrow{v} & Y \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f} \\ Z & \xrightarrow{u} & S \end{array}$$

By (i), the $\mathsf{R}^p f^!\mathbb{Z}/n$ have support in Y' for $p \leqslant -2d+1$; and the spectral sequence $\mathsf{R}^a v^!\mathsf{R}^b f^! \Rightarrow \mathsf{R}^{a+b}(fv)^!$ shows that they coincide with the $\mathsf{R}^p(fv)^!\mathbb{Z}/n = \mathsf{R}^p(uf)^!\mathbb{Z}/n$. Applying (i) to Y'/Z and to the spectral sequence $\mathsf{R}^a f^!\mathsf{R}^b u^! \Rightarrow \mathsf{R}^{a+b}(uf)^!$, one finds that (ii) follows from the vanishing of $\mathsf{R}^b u^!\mathbb{Z}/n$ for $b = 0$, or for $b = 0$ and 1, as the case may be.

2.2.9

Grothendieck conjectures the following absolute analogue of 2.2.8 (semipurity conjecture—a consequence of the purity conjecture): for Y of codimension $\geqslant c$ in a regular X, one has $\mathrm{H}^i_Y(X, \mathbb{Z}/n) = 0$ for $i < 2c$, at least if X is excellent.

2.2.10

We are now in a position to define the class of a cycle Y of codimension c in X smooth over a field k. Write $Y = \sum d_i Y_i$, where the Y_i are reduced and irreducible. An open subset U_i of Y_i, whose complement has codimension $> c$, is then a local complete intersection in X. This makes it possible to define the local fundamental class of U_i. By 2.2.6 and 2.2.8, it comes from a unique fundamental class $\mathrm{cl}(Y_i) \in \mathrm{H}^{2c}_{Y_i}(X, \mathbb{Z}/n(c))$, and we set

$$\mathrm{cl}(Y) = \sum d_i \,\mathrm{cl}(Y_i) \in \mathrm{H}^{2c}_{|Y|}(X, \mathbb{Z}/n(c))\,.$$

2.2.11

In complex analytic geometry, a construction of Baum, Fulton, and Mac Pherson [4] makes it possible to define without restriction the cohomology class of a local complete intersection $Y \subset X$. Suppose Y is purely of codimension c, and let $\mathscr{N}$ be the vector bundle on Y that is the normal bundle of Y in X. Its local sections are those of $(\mathscr{I}/\mathscr{I}^2)^\vee$, where $\mathscr{I}$ is the sheaf of ideals of Y. Recall that the sheaf of C^∞ functions on X is defined locally, in terms of local embeddings of X into $\mathbb{C}^n$, as the restriction to X of the quotient of the sheaf of C^∞ functions on $\mathbb{C}^n$ by the ideal generated by the real and imaginary parts of the equations defining X. The bundle $\mathscr{N}$ extends to a complex $C^\infty N$ vector bundle on a neighborhood U of Y in X, and for U sufficiently small, there exist sections f of N whose zero locus is Y and such that, on Y, $df : \mathscr{N} \to N$ is the identity. Two choices of N and f are homotopic on a sufficiently small neighborhood of Y.

The cohomology class $\mathrm{cl}(U)$ of the section 0 of N (denoted $z : U \to N$) is defined: U is a local complete intersection in N, and $\mathsf{R}^i z^! \mathbb{Z} = 0$ for $i \neq 2c$, $\mathsf{R}^{2c} z^! \mathbb{Z} = \mathbb{Z}$. We have $f^* : \mathrm{H}^\bullet_U(N, \mathbb{Z}) \to \mathrm{H}^\bullet_Y(X, \mathbb{Z})$ and set

$$\mathrm{cl}(Y) = f^* \,\mathrm{cl}(U).$$

The same construction works whenever an analytic subspace Y of X has the following normal structure: a locally free sheaf $\mathscr{C}$ of rank c on Y_{red}, and an epimorphism $\mathscr{C} \to \mathscr{I}/\mathscr{I} \cdot \mathscr{I}_{\mathrm{red}}$.

2.3 Homological method

2.3.1

Let $f : Y \to X$ be a flat morphism of finite type with fibers of dimension $\leqslant d$. In [2, XVIII 2.9], we defined a trace morphism

$$\mathrm{tr}_f : \mathsf{R}^{2d} f_! \mathbb{Z}/n(d) \to \mathbb{Z}/n. \tag{2.3.1.1}$$

One has $\mathsf{R}^i f_! \mathbb{Z}/n(d) = 0$ for $i > 2d$, and $\mathsf{R}^i f^! \mathbb{Z}/n = 0$ for $i < -2d$. This, together with the adjunction between $\mathsf{R}f_!$ and $\mathsf{R}f^!$, gives isomorphisms

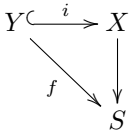
$$\begin{aligned} \hom\left(\mathsf{R}^{2d} f_! \mathbb{Z}/n(d), \mathbb{Z}/n\right) &= \hom\left(\mathsf{R}f_! \mathbb{Z}/n(d), \mathbb{Z}/n[-2d]\right) \\ &= \hom\left(\mathbb{Z}/n, \mathsf{R}f^! \mathbb{Z}/n(-d)[-2d]\right) \\ &= \mathrm{H}^0\left(Y, \mathsf{R}^{-2d} f^! \mathbb{Z}/n\right). \end{aligned} \tag{2.1.3.2}$$

At least when S is a point, the image of tr_f in the last two groups deserves the name fundamental class of Y (in homology).

We again denote by tr_f the image of tr_f in the second group, and the morphisms deduced from it by functoriality. For example, for Y/S proper, the morphism

$$\mathrm{H}^i\left(Y, \mathbb{Z}/n(d)\right) = \mathrm{H}^i\left(S, \mathsf{R}f_! \mathbb{Z}/n(d)\right) \longrightarrow \mathrm{H}^{i-2d}(S, \mathbb{Z}/n). \tag{2.3.1.3}$$

Suppose Y is contained in X, smooth over S and purely of relative dimension N, and set $c = N - d$.



One has $\mathsf{R}f^! = \mathsf{R}i^! \mathsf{R}g^!$, and $\mathsf{R}g^! \mathbb{Z}/n = \mathbb{Z}/n(-N)[-2N]$. The fundamental class of Y is identified with an element of $\mathrm{H}^0\left(Y, \mathsf{R}i^! \mathbb{Z}/n(c)[2c]\right) = \mathrm{H}^{2c}_Y\left(X, \mathbb{Z}/n(c)\right)$, the class $\mathrm{cl}(Y)$ of Y in X. We shall see below that it depends only on $Y \subset X$, not on the projection of X onto S, and that for Y a local complete intersection, it induces the local class of the preceding subsection.

Let us make explicit the isomorphism

$$\mathrm{H}^{2c}_Y\left(X, \mathbb{Z}/n(c)\right) \xrightarrow{\sim} \hom\left(\mathsf{R}^{2d} f_! \mathbb{Z}/n(d), \mathbb{Z}/n\right)$$

that takes $\mathrm{cl}(Y)$ to tr_f: via the isomorphisms

$$\begin{aligned} \mathrm{H}^{2c}_Y\left(X, \mathbb{Z}/n(c)\right) &= \mathrm{H}^{2c}_Y\left(\mathsf{R}i^! \mathbb{Z}/n(c)\right) \\ &= \hom_Y\left(\mathbb{Z}/n(d)[2d], \mathsf{R}i^! \mathbb{Z}/n(N)[2N]\right) \\ &= \hom_X\left(\mathbb{Z}/n(d)[2d]_Y, \mathbb{Z}/n(N)[2n]\right), \end{aligned}$$

it is the top row of

$$\begin{array}{ccccc} \mathrm{H}^{2c}_Y & \longrightarrow & \hom\left(\mathsf{R}f_!\mathbb{Z}/n(d)[2d], \mathsf{R}f_!\mathsf{R}i^!\mathbb{Z}/n(N)[2n]\right) & \xrightarrow{(1)} & \hom\left(\mathsf{R}f_!\mathbb{Z}/n(d)[2d], \mathbb{Z}/n\right) \\ & \searrow^{(3)} & \downarrow{\scriptstyle \mathrm{tr}_i} & & \| \\ & & \hom\left(\mathsf{R}g_!\mathbb{Z}/n(d)[2d]_Y, \mathsf{R}g_!\mathbb{Z}/n(N)[2N]\right) & \xrightarrow{\mathrm{tr}_g} & \hom\left(\mathsf{R}g_!\mathbb{Z}/n(d)[2d]_Y, \mathbb{Z}/n\right), \end{array}$$

where (1) is the adjunction arrow $\mathsf{R}f_!\mathsf{R}f^! \to \mathrm{id}$. The commutativity of (2) expresses the fact that the isomorphism $\mathsf{R}f^! = \mathsf{R}i^!\mathsf{R}g^!$ is defined by adjunction. Finally, the arrow deduced from (3)

$$\mathrm{H}^{2c}_Y\left(X, \mathbb{Z}/n(c)\right) \otimes \mathsf{R}^{2d}g_!\mathbb{Z}/n(d) \to \mathsf{R}^{2N}g_!\mathbb{Z}/n(N)$$

is interpreted as a cup product (cf. 1.2).

Definition 2.3.2. *The class* $\mathrm{cl}(Y) \in \mathrm{H}^{2c}_Y\left(X, \mathbb{Z}/n(c)\right)$ *is characterized by the property that, for every local section* u *of* $\mathsf{R}^{2d}f_!\mathbb{Z}/n(d)$*, one has*

$$\mathrm{tr}_f(u) = \mathrm{tr}_g\left(\mathrm{cl}(Y) \smile u\right).$$

Because $\mathrm{cl}(Y)$ already has an image tr_f in $\hom\left(\mathsf{R}f_!\mathbb{Z}/n(d)[2d], \mathbb{Z}/n\right)$, formula 2.3.2 holds for the arrows deduced from tr_f by functoriality. For example, for X proper over S and $u \in \mathrm{H}^\bullet(Y, \mathbb{Z}/n)$, the formula holds in $\mathrm{H}^\bullet\left(S, \mathbb{Z}/n(-d)\right)$. For $v \in \mathrm{H}^\bullet(X, \mathbb{Z}/n)$, it gives

$$\mathrm{tr}_f(i^*v) = \mathrm{tr}_g\left(\mathrm{cl}(Y) \smile v\right),$$

where the cup product can be computed in $\mathrm{H}^\bullet(X, \mathbb{Z}/n)$.

2.3.3

We shall define the trace morphisms, and hence the class $\mathrm{cl}(Y)$, under more general hypotheses. Consider a diagram

$$\begin{array}{ccc} Y & \hookrightarrow & X \\ & {\scriptstyle f}\searrow & \downarrow{\scriptstyle g} \\ & & S \end{array}$$

with g smooth and purely of relative dimension N, and Y closed in X with fiberwise dimension $\leqslant d$. Equip Y in addition with a "weight" $\mathscr{K}$ of the following kind: $\mathscr{K} \in \mathsf{D}^b_{\mathrm{parf},X}$ is a bounded complex of sheaves of $\mathscr{O}$-modules on X, of finite Tor-dimension over S (or over X, which amounts to the same thing), whose cohomology sheaves are coherent and have support in Y. We propose to define a morphism $\mathrm{tr}_{f,\mathscr{K}} : \mathsf{R}^{2d}f_!\mathbb{Z}/n(d) \to \mathbb{Z}/n$. For Y flat over S and $\mathscr{K} = \mathscr{O}_Y$, this will be the preceding trace morphism. In general, it depends only on the lengths of $\mathscr{K}$ at the generic points y of the irreducible components of Y ($\lg_y(\mathscr{K}) = \sum(-1)^i \lg \mathrm{H}^i(\mathscr{K})_y$). Finally, $\mathrm{cl}(Y, \mathscr{K})$ will denote the class with support in Y such that

$$\mathrm{tr}_g\left(\mathrm{cl}(Y, \mathscr{K}) \smile u\right) = \mathrm{tr}_{f,\mathscr{K}}(u). \tag{2.3.3.1}$$

2.3.4

The construction of $\mathrm{tr}_{f,\mathscr{K}}$ is parallel to that of [2, XVIII.2]; we shall indicate only its main outlines.

A $d = 0$ (f quasi-finite). Let x be a geometric point of Y, s its image in S, $\mathscr{K}_{(x)}$ the inverse image of $\mathscr{K}$ on the strict localization of X at x, $\mathscr{K}_{(x)s} = \mathscr{K}_{(x)} \overset{\mathsf{L}}{\otimes}_{\mathscr{O}^h_{S,s}} k(s)$ its inverse image on the geometric fiber at s, and $n(x) = \sum(-1)^i \dim_{k(s)} \mathrm{H}^i(\mathscr{K}_{(x)s})$. The function $x \mapsto n(x)$ is a weighting of f, and we take the corresponding trace morphism [2, XVII.6.2.5]. Formation of the weighting $n(x)$ and of $\mathrm{tr}_{f,\mathscr{K}}$ is compatible with every base change.

B General case. If $u : Z \to \mathbb{A}^d_S$ is such that ui is quasi-finite, set $\mathrm{tr}_{f,\mathscr{K}} = \mathrm{tr}_{\mathbb{A}^d_S} \circ \mathrm{tr}_{ui,\mathscr{K}}$. This trace morphism is clearly compatible with every base change S'/S. To prove that it does not depend on u, we may therefore suppose that S is the spectrum of an algebraically closed field k. In that case, let Y_i be the irreducible components of Y, and let lg_i be the length of $\mathscr{K}$ at the generic point of Y_i. If α_i is the inclusion of $(Y_i)_{\mathrm{red}}$ into Y, one has

$$\mathrm{tr}_{f,\mathscr{K}} = \sum \mathrm{lg}_i \, \mathrm{tr}_{Y_{i,\mathrm{red}/S}} \, \alpha_i^* \tag{2.3.4}$$

(this formula follows from the analogous and easy formula for tr_{ui}).

This defines $\mathrm{tr}_{f,\mathscr{K}}$ locally on Y; one then proceeds as in [2, XVIII.2.9].

Lemma 2.3.5. *If $g = g'g'' : X \xrightarrow{g''} S' \xrightarrow{g'} S$, with g' and g'' smooth and purely of relative dimensions N' and N'', and if Y still has fiberwise codimension $\geqslant c$ over S', then the class $\mathrm{cl}(Y, \mathscr{K})$ is the same whether computed in terms of g or of g''.*

Let $f' = g''i$ and $d' = d - N'$. The formula $\mathrm{tr}_g = \mathrm{tr}_{g'} \mathrm{tr}_{g''}$ ([2, XVIII.2.9] Var 3) ensures the commutativity of

$$\begin{array}{ccc}
 & \mathrm{H}^{2c}_X(Z, \mathbb{Z}/n(c)) & \\
 & \downarrow & \\
\hom_{S'}(\mathsf{R}f_!\mathbb{Z}/n(d')[2d'], \mathsf{R}g''_!\mathbb{Z}/n(N'')[2N'']) & \longrightarrow & \hom_{S'}\left(\mathsf{R}^{2d'} f'_!\mathbb{Z}/n, \mathbb{Z}/n\right) \\
\downarrow{\scriptstyle \mathsf{R}g'_!(N')} & & \downarrow{\scriptstyle \mathrm{tr}_{g'} \circ \mathsf{R}^{2N'} g'_!} \\
\hom_S(\mathsf{R}f_!\mathbb{Z}/n(d)[2d], \mathsf{R}g'_!\mathbb{Z}/n(N)[2N]) & \longrightarrow & \hom_S\left(\mathsf{R}^{2d} f_!\mathbb{Z}/n, \mathbb{Z}/n\right)
\end{array}$$

while the analogous and easily verified formula $\mathrm{tr}_{f,\mathscr{K}} = \mathrm{tr}_{g'} \mathrm{tr}_{f',\mathscr{K}}$ ensures that the image of $\mathrm{tr}_{f',\mathscr{K}}$ is $\mathrm{tr}_{f,\mathscr{K}}$. The assertion follows.

Lemma 2.3.6. *If Y is a divisor in X, the class of 2.3.2 coincides with the class of 2.1.2.*

By semipurity (2.2.6(i) and 2.2.8(i)), the problem is local on Y; using 2.3.5 to replace S by a suitable S', this allows us to suppose that $N = 1$. Using semipurity once more (2.2.6(ii) and 2.2.8(ii)), it suffices to prove 2.3.6 over the generic points of S. An étale localization then reduces us to assuming that S is the spectrum of an algebraically closed field k. Since the classes of 2.3.2 and 2.1.2 are each additive in Y, this reduces us to the case where Y is a closed point on a smooth curve over k. The fact that the characteristic property 2.3.2 is satisfied is then the fundamental compatibility 2.1.5.

Lemma 2.3.7. *The formation of $\mathrm{cl}(Y, \mathscr{K})$ is compatible with every base change S'/S.*

This follows from the same assertion for the trace morphisms.

Theorem 2.3.8. *(i)* $\mathrm{cl}(Y, \mathscr{K})$ *depends only on* $Y \subset X$ *and on the lengths of* $\mathscr{K}$ *at the generic points of* Y*. This class is additive in* $\mathscr{K}$*. For* $\mathscr{K} = \mathscr{O}_Y$ *and* Y *a local complete intersection, it induces the local class of 2.2.2.*

(ii) Let there be a commutative diagram

$$\begin{array}{ccc} X' & \xrightarrow{u} & X \\ \downarrow & & \downarrow \\ S' & \longrightarrow & S \end{array}$$

with X' *smooth over* S'*. If* $u^{-1}(Y)$ *still has fiberwise codimension* $\geqslant c$*, then*

$$\mathrm{cl}\left(u^{-1}(Y), \mathsf{L}u^*\mathscr{K}\right) = u^* \mathrm{cl}(Y, \mathscr{K}).$$

(iii) Let $Y' \subset X$ *have fiberwise codimension* $\geqslant c'$*, let* $\mathscr{K}'$ *be a weight on* Y'*, and suppose that* $Y \cap Y'$ *has fiberwise codimension* $\geqslant c + c'$*. Then*

$$\mathrm{cl}\left(Y \cap Y', \mathscr{K} \overset{\mathsf{L}}{\otimes} \mathscr{K}'\right) = \mathrm{cl}(Y, \mathscr{K}) \smile \mathrm{cl}(Y', \mathscr{K}').$$

(A) Given $Y \subset X/S$ as above, it follows from semipurity (2.2.6, 2.2.8) that to verify that two classes in $\mathrm{H}^{2c}_Y(X, \mathbb{Z}/n(c))$ coincide, it suffices to verify this locally at the generic points of Y, or even after every base change $s \to S$ (s a geometric generic point of S), at the generic points of Y.

(B) Proof of (ii) for $S = S'$ and u a closed immersion By localization (A), we may suppose that X' is the inverse image of the section 0 under a smooth morphism $v : X \to \mathbb{A}^{N'}_S$

$$\begin{array}{ccccc} X' & \xrightarrow{u} & X & & \\ \downarrow & & \downarrow{\scriptstyle v} & & \\ S & \xrightarrow{0} & \mathbb{A}^{N'}_S & \xrightarrow{\pi} & S \end{array}$$

Apply 2.3.5 to $g = \pi v$ and 2.3.7 to the base change $S \to \mathbb{A}^{N'}_S$.

(C) In a product situation: $X = X' \times_S X''$, $Y = Y' \times_S Y''$, $\mathscr{K} = \mathscr{K} \overset{\mathsf{L}}{\otimes}_S \mathscr{K}''$, one has $\mathrm{cl}(Y, \mathscr{K}) = \mathrm{cl}(Y, \mathscr{K}') \smile \mathrm{cl}(Y'', \mathscr{K}'')$ (external cup product, i.e. $\mathrm{pr}_1^* \mathrm{cl}(Y', \mathscr{K}') \smile \mathrm{pr}_2^* \mathrm{cl}(Y'', \mathscr{K}'')$).

The functorial properties of tr_g [2, XVIII.2.12] imply the commutativity of

$$\begin{array}{ccccc} \mathrm{H}^{2c'}_{X'} \otimes \mathrm{H}^{2c''}_{X''} & \longrightarrow & \hom_S\left(\mathsf{R}f'_!\mathbb{Z}/n(d')[2d'], \mathsf{R}g'_!\mathbb{Z}/n(N')[2N']\right) \otimes \cdots & \longrightarrow & \hom_S\left(\mathsf{R}^{2d'} f'_!\mathbb{Z}/n, \mathbb{Z}/n\right) \otimes \cdots \\ \downarrow & & \downarrow & & \downarrow \\ \mathrm{H}^{2c}_X & \longrightarrow & \hom_S\left(\mathsf{R}f_!\mathbb{Z}/n(d)[2d], \mathsf{R}g_!\mathbb{Z}/n(N)[2N]\right) & \longrightarrow & \hom_S\left(\mathsf{R}^{2d} f_!\mathbb{Z}/n, \mathbb{Z}/n\right) \end{array}$$

and one verifies that tr_f is the image of $\mathrm{tr}_{f'} \otimes \mathrm{tr}_{f''}$, whence the assertion.

Proof of (ii) (2.3.7) and a preliminary base change reduce us to assuming that $S = S'$. Factor u through its graph:

$$X' \xrightarrow{(\mathrm{id}, u)} X' \times X \xrightarrow{\mathrm{pr}_2} X.$$

This leads us to treat pr_2 and (id, u) separately: the former is covered by (C) with $X' = X'$, $\mathscr{K}' = \mathscr{O}_{x'}$ (with $\mathrm{cl}(Y') = 1 \in \mathrm{H}^0(X, \mathbb{Z}/n)$), and the latter by (B).

Proof of (iii) Let $\delta : X \to X \times_S X$ be the diagonal inclusion. We use the formula $\delta^*(Y_1 \times_S Y_2) = Y_1 \cap Y_2$ to reduce to (B) and (C).

Proof of (i) The base change $S_{\mathrm{red}} \to S$ replaces X by X_{red}; this reduces us to assuming X and S reduced. Localization near the generic points of Y then reduces us to the case where Y_{red} is irreducible and the complete intersection of c divisors D_i. The same localization, together with the definition of tr in the quasi-finite case, then shows that $\mathrm{cl}(Y, \mathscr{K}) = \lg \mathrm{cl}(Y_{\mathrm{red}}, \mathscr{O}_{Y_{\mathrm{red}}})$, where lg is the length of $\mathscr{K}$ at the generic point of Y. By (iv), one therefore has

$$\mathrm{cl}(Y, \mathscr{K}) = \lg \prod_i \mathrm{cl}(D_i, \mathscr{O}_{D_i})$$

and the conclusion follows from 2.3.6.

2.3.9 Remark

For S the spectrum of a field, with the class of a cycle defined as in 2.2.10, assertion (iii) says that if two cycles Y' and Y'' intersect with the correct dimension, then

$$\mathrm{cl}(Y' \cap Y'') = \mathrm{cl}(Y') \smile \mathrm{cl}(Y''),$$

provided that the multiplicities of the components of $Y' \cap Y''$ are computed as alternating sums of Tor.

2.3.10 Remark

Let $X/\operatorname{Spec}(k)$, with k algebraically closed. If two cycles of codimension c in X are algebraically equivalent, the existence of the relative theory above implies that the images in $\mathrm{H}^{2c}(X, \mathbb{Z}/n(c))$ of their classes are the fibers, at two points of a suitable connected S, of a section over S of the constant sheaf $\mathrm{H}^{2c}(X, \mathbb{Z}/n(c))$ (the sheaf $\mathsf{R}^{2c} f_* \mathbb{Z}/n(c)$ for $f = \mathrm{pr}_2 : X \times S \to S$): two algebraically equivalent cycles have the same class in $\mathrm{H}^{2c}(X, \mathbb{Z}/n(c))$.

3 Application: the Lefschetz trace formula in the proper smooth case

3.1

Let X and Y be proper smooth algebraic varieties over an algebraically closed field k, purely of dimensions N and M. Via the Künneth isomorphism $\mathrm{H}^\bullet(X \times Y) = \mathrm{H}^\bullet(X) \otimes \mathrm{H}^\bullet(Y)$, the trace morphism $\mathrm{H}^\bullet(X \times Y)(M) \to \mathrm{H}^\bullet(X)$ is simply $\mathrm{H}^\bullet(X) \otimes$ (the trace morphism $\mathrm{H}^\bullet(Y)(M) \to \mathbb{Q}_\ell$). Since the morphism is homogeneous of even degree, there is no sign problem. We denote it by $\int_Y$.

3.2

A class $\eta \in \mathrm{H}^{2q}(X \times Y)(q)$ defines a morphism of degree $2(q - N)$, $\eta_{XY} : \mathrm{H}^\bullet(Y)(N - q) \to \mathrm{H}^\bullet(X)$, by the formula

$$\beta \mapsto \int_Y \eta \cdot \mathrm{pr}_2^* \beta.$$

Proposition 3.3. *Let p and q be two integers, with $p+q = N+M$, and let $\varepsilon \in \mathrm{H}^{2p}(X\times Y)(p)$, $\eta \in \mathrm{H}^{2q}(X\times Y)(p)$. With the trace of $\eta_{XY}\varepsilon_{YX} : \mathrm{H}^\bullet(X) \to \mathrm{H}^\bullet(X)$ understood in the sense of 1.3, one has*

$$\mathrm{tr}_{X\times Y}(\eta\cdot\varepsilon) = \mathrm{tr}\left(\eta_{XY}\varepsilon_{YX}, \mathrm{H}^\bullet(X)\right).$$

To exorcise the signs, it is helpful to retain from the grading of $\mathrm{H}^\bullet$ only the underlying $\mathbb{Z}/2$-grading. To avoid carrying Tate twists along, also fix an isomorphism $\mathbb{Q}_\ell(1) = \mathbb{Q}_\ell$. Let α_Y be the homomorphism $\mathrm{H}^\bullet(Y) \to \mathrm{H}^\bullet(Y)^\vee$ (an isomorphism) that makes the diagram

$$\begin{array}{ccccc} \mathrm{H}^\bullet(Y)\otimes\mathrm{H}^\bullet(Y) & \longrightarrow & \mathrm{H}^\bullet(Y) & \xrightarrow{\mathrm{tr}} & \mathbb{Q}_\ell \\ \downarrow{\scriptstyle \alpha_Y\otimes 1} & & & & \| \\ \mathrm{H}^\bullet(Y)^\vee\otimes\mathrm{H}^\bullet(Y) & & \xrightarrow{(1.3.1)} & & \mathbb{Q}_\ell. \end{array}$$

commute. The map η_{XY} is the image of η under

$$\mathrm{H}^\bullet(X\times Y) = \mathrm{H}^\bullet(X)\otimes\mathrm{H}^\bullet(Y) \xrightarrow{\alpha_Y} \mathrm{H}^\bullet(X)\otimes\mathrm{H}^\bullet(Y)^\vee \overset{(1.3.2)}{=\!=} \hom\left(\mathrm{H}^\bullet(X), \mathrm{H}^\bullet(Y)\right),$$

and likewise for ε. Definition 1.3.4 of the trace then reduces 3.3 to the formula $\mathrm{tr}_{X\times Y} = \mathrm{tr}_X \otimes \mathrm{tr}_Y$.

3.4 Remark

The proof of 3.4 does not use the fact that α_X and α_Y are isomorphisms. It is valid without assuming X and Y smooth. Outside the smooth case, however, it is difficult to find *cohomology* classes to which one would want to apply 3.3.

3.5 Remark

If ε, η are the cohomology classes of algebraic cycles A and B on $X\times Y$, of codimensions p and q, and $A\cap B$ has dimension 0, then $\mathrm{tr}_{X\times Y}(\eta\varepsilon)$ is the intersection multiplicity $A\cdot B$, computed by an alternating sum of Tor (2.3.9).

Proposition 3.6. *For $q = M$ and $\eta = \mathrm{cl}(B)$ the class of a subscheme $B \subset X\times Y$, finite over X, the map η_{XY} is the composite*

$$\eta_{XY} : \mathrm{H}^\bullet(Y) \xrightarrow{\mathrm{pr}_2^*} \mathrm{H}^\bullet(B) \xrightarrow{\mathrm{tr}_{B/X}} \mathrm{H}^\bullet(X).$$

Indeed, by 3.2 and (2.3.3.1) for $\mathscr{K} = \mathscr{O}_B$, one has

$$\eta_{XY}(\beta) = \mathrm{tr}_{X\times Y/X}\left(\mathrm{cl}(B)\cdot \mathrm{pr}_2^*\,\beta\right) = \mathrm{tr}_{B/X}\left(\mathrm{pr}_2^*\,\beta\right).$$

The most important case is that in which B is the graph of a map $f : X \to Y$. In this case, 3.6 shows that $\eta_{XY} = f^*$.

Corollary 3.7. *Let f be an endomorphism of X proper and smooth over an algebraically closed field k. Suppose that the fixed points of f are isolated. Then the trace $\sum(-1)^i \mathrm{tr}(f^*, \mathrm{H}^i(X))$ is the number of fixed points of f, each counted with its multiplicity.*

In 3.5, take $A =$ the graph of the identity and $B =$ the graph of f, and apply 3.3, 3.6.

Corollary 3.8. *Let X be a curve over an algebraically closed k, obtained by extension of scalars from X_0 over $\mathbb{F}_q$, and let f be the Frobenius morphism. Then $\sum(-1)^i \operatorname{tr}(f^*, \mathrm{H}^\bullet_c(X))$ is the number of fixed points of f.*

One can replace X by X_{red}, and hence suppose that X is reduced. Let U be the open subset of X on which X is smooth of dimension 1, and let $\bar{U}$ be the smooth projective completion of U. The long exact cohomology sequences for (X, U) and $(\bar{U}, U)$ give

$$\operatorname{tr}(f^*, \mathrm{H}^\bullet_c(X)) = \operatorname{tr}(f^*, \mathrm{H}^\bullet_c(U)) + \operatorname{tr}(f^*, \mathrm{H}^\bullet_c(X \smallsetminus U))$$

and

$$\operatorname{tr}\left(f^*, \mathrm{H}^\bullet_c(\bar{U})\right) = \operatorname{tr}(f^*, \mathrm{H}^\bullet_c(U)) + \operatorname{tr}\left(f^*, \mathrm{H}^\bullet_c(\bar{U} \smallsetminus U)\right).$$

The same formulas hold for the numbers of fixed points. Since formula 3.8 is clear for a scheme of dimension 0, this reduces us to proving 3.8 for $\bar{U}$. This case follows from 3.7. The fact that $df = 0$ guarantees that all fixed points have multiplicity one.

3.9 Remark

For X of dimension $\leqslant 1$ over an algebraically closed k, and $f : X \to X$ such that $df = 0$, it is not difficult to verify that 3.8 is still valid.

Chapter 5

Duality

This exposé contains several theorems and compatibility results, all related to Poincaré duality. In Section 1, we give the local biduality theorem in dimension 1 [21, I.5.1], together with some computations of duals. In Section 2, we give a very economical proof of Poincaré duality for curves, taught to me by M. Artin. In Section 3, we prove a compatibility linking two definitions of the pairing giving rise to Poincaré duality for curves: one by cup product, the other by autoduality of the Jacobian. Finally, in Section 4, we prove the compatibility announced in the title.

Throughout the exposé, all schemes are noetherian and separated, and n is an integer invertible on every scheme under consideration.

1 Local biduality in dimension 1

1.1

Let S be a regular scheme, purely of dimension 1. We shall show that the complex with value $\mathbb{Z}/n$ concentrated in degree 0 is dualizing; that is, for $\mathscr{K} \in \mathrm{Ob}\,\mathsf{D}_c^b(S, \mathbb{Z}/n)$ (where $(-)_c$ means constructible), if we put $D\mathscr{K} = \mathsf{R}\mathscr{H}om(\mathscr{K}, \mathbb{Z}/n)$, then $D\mathscr{K}$ is again constructible with bounded cohomology, and the canonical morphism α from $\mathscr{K}$ to $DD\mathscr{K}$ is an isomorphism.

For $\mathscr{K}$ in D^- and arbitrary $\mathscr{L}$, we have

$$\hom(\mathscr{K} \overset{\mathsf{L}}{\otimes} \mathscr{L}, \mathbb{Z}/n) = \hom(\mathscr{L}, \mathscr{H}om(\mathscr{K}, \mathbb{Z}/n)).$$

The morphism from $\mathscr{K}$ to $DD\mathscr{K}$ is defined when $D\mathscr{K}$ lies in D^-: if $\beta : D\mathscr{K} \overset{\mathsf{L}}{\otimes} \mathscr{K} \to \mathbb{Z}/n$ is the canonical pairing, it is the morphism defined by the pairing $\mathscr{K} \overset{\mathsf{L}}{\otimes} D\mathscr{K} = D\mathscr{K} \overset{\mathsf{L}}{\otimes} \mathscr{K} \xrightarrow{\beta} \mathbb{Z}/n$.

1.2

Let $f : X \to S$ be a separated morphism of finite type. Put $\mathscr{K}_X = \mathsf{R}f^!\mathbb{Z}/n$. For $\mathscr{K} \in \mathrm{Ob}\,\mathsf{D}^-(X, \mathbb{Z}/n)$, put $D\mathscr{K} = \mathsf{R}\mathscr{H}om(\mathscr{K}, \mathscr{K}_X)$. The adjunction between $\mathsf{R}f_!$ and $\mathsf{R}f^!$ gives

$$\mathsf{R}f_*\mathscr{K} \overset{\mathsf{L}}{\otimes} \mathsf{R}f_*D\mathscr{K} \longrightarrow \mathsf{R}f_!(\mathscr{K} \overset{\mathsf{L}}{\otimes} D\mathscr{K}) \longrightarrow \mathsf{R}f_!\mathsf{R}f^!\mathbb{Z}/n \longrightarrow \mathbb{Z}/n.$$

The symmetry of this description shows that, when f is proper, the diagram

$$\begin{array}{ccc} \mathsf{R}f_*\mathscr{K} & \longrightarrow & DD\mathsf{R}f_*\mathscr{K} \\ \downarrow & & \downarrow\wr \\ \mathsf{R}f_*DD\mathscr{K} & \xrightarrow{\sim} & D\mathsf{R}f_*D\mathscr{K} \end{array} \tag{1.2.1}$$

is commutative.

If f is the inclusion of a closed point, we know that $\mathsf{R}f^!\mathbb{Z}/n = \mathbb{Z}/n(-1)[-2]$—that is, up to a twist and a shift, $\mathbb{Z}/n$. Over the spectrum of a field this complex is dualizing (Pontryagin duality for $\mathbb{Z}/n$-modules). By (1.2.1), we therefore have $\mathscr{K} \xrightarrow{\sim} DD\mathscr{K}$ for $\mathscr{K}$ of the form $\mathsf{R}f_!\mathscr{L}$, and hence whenever the support of $\underline{\mathrm{H}}^\bullet(\mathscr{K})$ is finite.

Theorem 1.3. *Let $j : U \hookrightarrow S$ be a dense open subscheme of S, and let $\mathscr{F}$ be a locally constant constructible sheaf of $\mathbb{Z}/n$-modules on U. Then $\mathsf{D}j_*\mathscr{F} = j_*D\mathscr{F}$; that is, $\mathscr{H}om(j_*\mathscr{F}, \mathbb{Z}/n) = j_*\mathscr{H}om(\mathscr{F}, \mathbb{Z}/n)$ and $\mathscr{E}xt^i(j_*\mathscr{F}, \mathbb{Z}/n) = 0$ for $i > 0$.*

On U, $\mathscr{E}xt^i(j_*\mathscr{F}, \mathbb{Z}/n) = 0$ for $i > 0$, since $\mathscr{F}$ is locally constant (and $\mathbb{Z}/n$ is an injective $\mathbb{Z}/n$-module), while for $i = 0$ it is the dual $\mathscr{F}^\vee$ of $\mathscr{F}$. One checks that $\hom(j_*\mathscr{F}, \mathbb{Z}/n) = j_*\mathscr{F}^\vee$, and it remains to verify the vanishing of the $\mathscr{E}xt^i$ for $i > 0$ at the points of $S \smallsetminus U$. The problem is local at these points. We are thus reduced to assuming that S is a strictly local trait and that U consists of its generic point η. Let $I = \mathrm{Gal}(\bar\eta/\eta)$. The sheaf $\mathscr{F}$ is identified with the Galois module $\mathscr{F}_{\bar\eta}$, and the special fiber of $j_*\mathscr{F}$ with $\mathscr{F}_{\bar\eta}^I$.

Let i be the inclusion of the closed point s, and apply D to the exact sequences

$$\begin{array}{ccccccccc} 0 & \longrightarrow & j_!\mathscr{F} & \longrightarrow & j_*\mathscr{F} & \longrightarrow & i_*\mathscr{F}_{\bar\eta}^I & \longrightarrow & 0 \\ & & \uparrow & & \uparrow & & \uparrow & & \\ 0 & \longrightarrow & j_!\mathscr{F}_{\bar\eta}^I & \longrightarrow & \mathscr{F}_{\bar\eta}^I & \longrightarrow & i_*\mathscr{F}_{\bar\eta}^I & \longrightarrow & 0. \end{array}$$

We obtain a morphism of triangles

$$\begin{array}{ccccc} i_*\left(\mathscr{F}_{\bar\eta}^I\right)^\vee(-1)[-2] & \longrightarrow & Dj_*\mathscr{F} & \longrightarrow & \mathsf{R}j_*\mathscr{F}^\vee \\ \| & & \downarrow & & \downarrow \\ i_*\left(\mathscr{F}_{\bar\eta}^I\right)^\vee(-1)[-2] & \longrightarrow & \left(\mathscr{F}_{\bar\eta}^I\right)^\vee & \longrightarrow & \mathsf{R}j_*\mathscr{F}_{\bar\eta}^I. \end{array}$$

The long exact sequence arising from the first row gives the vanishing of the $\mathscr{E}xt^i$ for $i > 2$, and, on taking the fiber at s, we find

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \left(\underline{\mathrm{H}}^1(Dj_*\mathscr{F}\right)_s & \longrightarrow & \mathrm{H}^1\left(I, \mathscr{F}_{\bar\eta}^\vee\right) & \xrightarrow{\partial} & \left(\mathscr{F}_{\bar\eta}^I\right)^\vee(-1) & \longrightarrow & \left(\underline{\mathrm{H}}^2 Dj_*\mathscr{F}\right)_s \longrightarrow 0 \\ & & & & \downarrow & & \| & & \\ & & 0 & \longrightarrow & \mathrm{H}^1\left(I, (\mathscr{F}_{\bar\eta}^I)^\vee\right) & \xrightarrow{\partial} & \left(\mathscr{F}_{\bar\eta}^I\right)^\vee(-1) & \longrightarrow & 0. \end{array}$$

Since $\left(\mathscr{F}_{\bar\eta}^I\right)^\vee = \left(\mathscr{F}_{\bar\eta}^\vee\right)_I$, putting $M = \mathscr{F}_{\bar\eta}^\vee$, it remains only to check that

$$\mathrm{H}^1(I, M) \xrightarrow{\sim} \mathrm{H}^1(I, M_I).$$

If p is the residual characteristic exponent, then I is an extension of a group isomorphic to $\widehat{\mathbb{Z}}_{p'} = \varprojlim_{(m,p)=1} \mathbb{Z}/m$ by a p-group P. Since the order of P is prime to the order of M, we have $\mathrm{H}^1(P, M) = 0$ for $i > 0$ and $(M_I)^P = (M^P)_I$. This allows us to replace M by M^P and I by I/P. Finally, there is a functorial isomorphism $\mathrm{H}^1(\widehat{\mathbb{Z}}_{p'}, M) \sim$ (coinvariants of $\widehat{\mathbb{Z}}_{p'}$ in M), which proves the theorem.

Theorem 1.4. *For $\mathscr{K} \in \mathrm{Ob}\, \mathsf{D}_c^b(S, \mathbb{Z}/n)$, one has $\mathscr{K} \xrightarrow{\sim} DD\mathscr{K}$.*

By dévissage, we reduce to the case in which $\mathscr{K}$ is a constructible sheaf $\mathscr{F}$ concentrated in degree 0, and $\mathscr{F}$ either has finite support (1.2) or is of the form $j_*\mathscr{F}_1$ as in 1.3. In the second case, 1.3 reduces us to local biduality for $\mathscr{F}$ locally constant on U.

2 Poincaré duality for curves, after M. Artin

2.1

Let X be a smooth projective curve over an algebraically closed field k. Put $\mathscr{K}_X = \mathbb{Z}/n(1)[2]$ and, for $\mathscr{K} \in \mathrm{Ob}\, \mathsf{D}_c^b(X, \mathbb{Z}/n)$, $D\mathscr{K} = \mathsf{R}\mathscr{H}om(\mathscr{K}, \mathscr{K}_X)$. For M a $\mathbb{Z}/n$-module, also put $DM = \hom(M, \mathbb{Z}/n)$, and similarly for complexes of modules. The trace morphism $\mathrm{H}^0(X, \mathscr{K}_X) \to \mathbb{Z}/n$, or $\mathsf{R}\Gamma(X, \mathscr{K}_X) \to \mathbb{Z}/n$, defines a pairing $\mathsf{R}\Gamma(X, \mathscr{K}) \overset{\mathsf{L}}{\otimes} \mathsf{R}\Gamma(X, D\mathscr{K}) \to \mathbb{Z}/n$. Poincaré duality between the cohomology and compactly supported cohomology of an open subscheme $j : U \hookrightarrow X$ of the curve X says that, for $\mathscr{K} = j_!\mathbb{Z}/n$, this pairing identifies each factor with the dual of the other.

I give below a proof, communicated to me by M. Artin, that for $\mathscr{K} \in \mathrm{Ob}\, \mathsf{D}_c^b(X, \mathbb{Z}/n)$ this pairing is always perfect; that is, it defines an isomorphism

$$\mathsf{R}\Gamma(X, \mathscr{K}) \xrightarrow{\sim} D\mathsf{R}\Gamma(X, D\mathscr{K}). \tag{2.1.1}$$

For every constructible sheaf $\mathscr{F}$, put

$$'\mathrm{H}^i(X, \mathscr{F}) = \text{the } \mathbb{Z}/n\text{-dual of } \mathrm{H}^{-i}(X, D\mathscr{F}).$$

The assertion that (2.1.1) is an isomorphism is equivalent to the following theorem.

Theorem 2.2. *For a constructible sheaf $\mathscr{F}$ of $\mathbb{Z}/n$-modules, one has*

$$\mathrm{H}^i(X, \mathscr{F}) \xrightarrow{\sim} {}'\mathrm{H}^i(X, \mathscr{F}). \tag{2.2.1}$$

Lemma 2.3. *Let $f : X \to Y$ be a generically étale morphism between smooth curves over k. Then $\mathscr{K}_X = f^*\mathscr{K}_Y = \mathsf{R}f^!\mathscr{K}_Y$, with tr_f as the adjunction morphism $\mathsf{R}f_!\mathsf{R}f^!\mathscr{K}_Y \to \mathscr{K}_Y$.*

We reduce to checking that, for f finite, $f_*\mathsf{R}f^!\mathscr{K}_Y = \mathsf{R}\mathscr{H}om(f_*\mathbb{Z}/n, \mathscr{K}_Y)$ is $f_*\mathbb{Z}/n$, with tr_f as the adjunction morphism. The vanishing of the $\mathscr{E}xt^i$ for $i > 0$ follows from 1.3, and the assertion follows.

More explicitly, $\mathsf{R}f^!$ is the derived functor of the functor $f^! : f^!\mathscr{F}(U) = \hom(f_!\mathbb{Z}_U, \mathscr{F})$, and 1.3 implies the vanishing of $\mathsf{R}^i f^!\mathbb{Z}/n$ for $i > 0$.

Corollary 2.4. *Let $f : X' \to X$ be a generically étale morphism of smooth projective curves over k. Then $'\mathrm{H}^i(X, f_*\mathscr{F}) =' \mathrm{H}^i(X', \mathscr{F})$; this isomorphism is functorial, and the diagram*

$$\begin{array}{ccc} \mathrm{H}^i(X, f_*\mathscr{F}) & \longrightarrow & {}'\mathrm{H}^i(X, f_*\mathscr{F}) \\ \| & & \| \\ \mathrm{H}^i(X', \mathscr{F}) & \longrightarrow & {}'\mathrm{H}^i(X', \mathscr{F}) \end{array}$$

is commutative.

The isomorphism is given by 1.2: $Df_*\mathscr{F} = f_*D\mathscr{F}$.

2.5

We prove 2.2. If $\mathscr{F}$ is $\mathbb{Z}/n$ at one point, extended by 0, then $\mathrm{H}^\bullet(D\mathscr{F}) = \mathrm{Ext}^\bullet(\mathscr{F}, \mathscr{K}_X) = \mathbb{Z}/n$ in degree 0, and in the pairing $\mathrm{H}^\bullet(\mathscr{F}) \otimes \mathrm{H}^\bullet(D\mathscr{F}) \to \mathbb{Z}/n$, one has $1 \otimes 1 \mapsto 1$ (Cycle, 2.1.5): the duality is perfect. The case in which $\mathscr{F}$ has finite support is treated in the same way.

For arbitrary constructible $\mathscr{F}$, let $\mathscr{A}$ be the subsheaf of its sections with finite support, and let $\mathscr{G} = \mathscr{F}/\mathscr{A}$. The exact sequence

$$0 \longrightarrow \mathscr{A} \longrightarrow \mathscr{F} \longrightarrow \mathscr{G} \longrightarrow 0 \tag{2.5.1}$$

gives a diagram

$$\begin{array}{ccccccccc} & & & & 0 & \longrightarrow & \mathrm{H}^0(X,\mathscr{A}) & \longrightarrow & \mathrm{H}^0(X,\mathscr{F}) \longrightarrow \mathrm{H}^0(X,\mathscr{G}) \longrightarrow 0 \\ & & & & & & \downarrow\wr & & \downarrow \qquad \downarrow \\ 0 \to {}' \mathrm{H}^{-1}(X,\mathscr{F}) & \to & {}' \mathrm{H}^{-1}(X,\mathscr{F}) & \to & {}' \mathrm{H}^0(X,\mathscr{A}) & \to & {}' \mathrm{H}^0(X,\mathscr{F}) & \to & {}' \mathrm{H}^0(X,\mathscr{F}) \to 0 \end{array} \tag{2.5.2}$$

and compatible isomorphisms $\mathrm{H}^i(X,\mathscr{F}) \xrightarrow{\sim} \mathrm{H}^i(X,\mathscr{G})$, ${}' \mathrm{H}^i(X,\mathscr{F}) \xrightarrow{\sim}{}' \mathrm{H}^i(X,\mathscr{G})$ for $i \neq 0, -1$. If $j : U \to X$ is an open subscheme on which $\mathscr{F}$ is locally constant, there is an exact sequence

$$0 \longrightarrow \mathscr{G} \longrightarrow j_*j^*\mathscr{F} \longrightarrow \mathscr{B} \longrightarrow 0 \tag{2.5.3}$$

with $\mathscr{B}$ of finite support. Since ${}' \mathrm{H}^i(X, j_*j^*\mathscr{F}) = D\,\mathrm{H}^{2-i}(X, j_*(j^*\mathscr{F})^\vee(1))$ by 1.3, one has ${}' \mathrm{H}^i = 0$ for $i < 0$; then (2.5.2) and the long exact sequence defined by (2.5.3) show that ${}' \mathrm{H}^i$ always vanishes for $i < 0$.

If $\mathscr{F} = \mathbb{Z}/n$, the theorem is true for $i = 0$ and 2. This expresses the fact that, for connected X, the trace morphism $\mathrm{H}^2(X, \boldsymbol{\mu}_n) \xrightarrow{\sim} \mathbb{Z}/n$ is an isomorphism. By 2.4, the theorem remains true for $i = 0$ and $\mathscr{F} = f_*\mathbb{Z}/n$.

For arbitrary $\mathscr{F}$ again, with $\mathscr{G}$ as above, there exists $f : X' \to X$ as in 2.4 such that $\mathscr{G}$ embeds into $f_*\mathbb{Z}/n$:

$$0 \longrightarrow \mathscr{G} \longrightarrow f_*\mathbb{Z}/n \longrightarrow \mathscr{Q} \longrightarrow 0.$$

After replacing X' by an X''/X', we may assume that $\mathrm{H}^i(X,\mathscr{F}) \to \mathrm{H}^i(X, f_*\mathbb{Z}/n) = \mathrm{H}^i(X', \mathbb{Z}/n)$ is zero for $i > 0$. Consider then

$$\begin{array}{ccccccccccc} 0 \to \mathrm{H}^0(X,\mathscr{G}) & \to & \mathrm{H}^0(S',\mathbb{Z}/n) & \to & \mathrm{H}^0(X,\mathscr{Q}) & \to & \mathrm{H}^1(X,\mathscr{G}) & \xrightarrow{0} & \mathrm{H}^1(X',\mathbb{Z}/n) & \to & \mathrm{H}^1(X,\mathscr{Q}) \to \cdots \\ \downarrow & & \downarrow\wr & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\ 0 \to {}' \mathrm{H}^0(X,\mathscr{G}) & \to & {}' \mathrm{H}^0(X',\mathbb{Z}/n) & \to & {}' \mathrm{H}^0(X,\mathscr{Q}) & \to & {}' \mathrm{H}^1(X,\mathscr{G}) & \to & {}' \mathrm{H}^1(X',\mathbb{Z}/n) & \to & {}' \mathrm{H}^1(X,\mathscr{Q}) \to \cdots \end{array}$$

The isomorphism at $\mathrm{H}^0(X')$ gives $\mathrm{H}^0(X,\mathscr{G}) \hookrightarrow {}' \mathrm{H}^0(X,\mathscr{G})$, and the same injectivity for $\mathscr{F}$ by (2.5.2). Applied to $\mathscr{Q}$, this gives $\mathrm{H}^1(X,\mathscr{G}) \hookrightarrow {}' \mathrm{H}^1(X,\mathscr{G})$. We apply this to $\mathrm{H}^1(X', \mathbb{Z}/n)$. This group has the same order as ${}' \mathrm{H}^1(X', \mathbb{Z}/n) = D(\mathrm{H}^1(X', \mathbb{Z}/n)(1))$, so we obtain an isomorphism, and $\mathrm{H}^1(X,\mathscr{G}) \xrightarrow{\sim}{}' \mathrm{H}^1(X,\mathscr{G})$. The same holds for $\mathscr{F}$. For $i = 2$, we already know that $\mathrm{H}^2(X', \mathbb{Z}/n) \xrightarrow{\sim}{}' \mathrm{H}^2(X', \mathbb{Z}/n)$, and proceed in the same way, then stop for lack of combatants.

3 Poincaré duality for curves

In this section we prove the compatibility (Arcata 6.2.2.3).

3.1

We use the notation of (Arcata 6.2.3): $\bar{X}$ is a smooth, connected, projective curve over an algebraically closed field k, D is a reduced divisor on $\bar{X}$, and 0 is a point of $X = \bar{X} \smallsetminus D$,

$$X \overset{j}{\hookrightarrow} \bar{X} \overset{i}{\hookleftarrow} D,$$

and $\mathrm{Pic}_D(\bar{X}) = \mathrm{H}^1(\bar{X}, {}_D\mathbb{G}_m)$, where ${}_D\mathbb{G}_m$ is the sheaf of sections of $\mathbb{G}_m$ congruent to 1 mod D. Recall that $\mathrm{H}^1(X, \boldsymbol{\mu}_n) = \mathrm{Pic}^0_D(\bar{X})_n$, and that $x \to \mathscr{O}(x)$ defines a canonical map $f : X \to \mathrm{Pic}_D(\bar{X})$. Put $f_0(x) = f(x) - f(0) : X \to \mathrm{Pic}^0_D(\bar{X})$.

Again write j for the inclusion of $X \times X$ in $X \times \bar{X}$. The diagonal Δ of $X \times X$ is closed in $X \times \bar{X}$; it defines a class in $\mathrm{H}^2_\Delta(X \times X, \boldsymbol{\mu}_n) = \mathrm{H}^2_\Delta(X \times \bar{X}, j_!\boldsymbol{\mu}_n)$. Let c denote its image in $\mathrm{H}^2(X \times \bar{X}, j_!\boldsymbol{\mu}_n)$.

The Künneth formula gives

$$\mathrm{H}^\bullet(X \times \bar{X}, j_!\boldsymbol{\mu}_n) = \mathrm{H}^\bullet(X, \mathbb{Z}/n) \otimes \mathrm{H}^\bullet(\bar{X}, j_!\boldsymbol{\mu}_n) = \mathrm{H}^\bullet(X, \mathbb{Z}/n) \otimes \mathrm{H}^\bullet_c(X, \boldsymbol{\mu}_n).$$

We shall compute the $(1,1)$-component of c,

$$c^{1,1} \in \mathrm{H}^1(X, \mathbb{Z}/n) \otimes \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) = \mathrm{H}^1(X, \mathrm{H}^1_c(X, \boldsymbol{\mu}_n)) = \mathrm{H}^1\left(X, \mathrm{Pic}^0_D(\bar{X})_n\right).$$

Consider the exact sequence

$$0 \longrightarrow \mathrm{Pic}^0_D(\bar{X})_n \longrightarrow \mathrm{Pic}^0_D(\bar{X}) \overset{n}{\longrightarrow} \mathrm{Pic}^0_D(\bar{X}) \longrightarrow 0$$

This makes $\mathrm{Pic}^0_D(\bar{X})$ a torsor under $\mathrm{Pic}^0_D(\bar{X})_n$ over $\mathrm{Pic}^0_D(\bar{X})$. Let u be the class, in $\mathrm{H}^1(X, \mathrm{H}^1_c(X, \boldsymbol{\mu}_n)) = \mathrm{H}^1(X, \mathrm{Pic}^0_D(\bar{X})_n)$, of its inverse image under f_0.

Proposition 3.2. *With the preceding notation, $c^{1,1} = -u$.*

Let e be the difference between the images in $\mathrm{H}^2(X \times \bar{X}, j_!\boldsymbol{\mu}_n)$ of the cohomology classes of Δ and $X \times \{0\}$. Since the latter is of Künneth type $(0,2)$, one has $c^{1,1} = e^{1,1}$. Consider the Leray spectral sequence for $\mathrm{pr}_1 : X \times \bar{X} \to X$ and the sheaf $j_!\boldsymbol{\mu}_n$:

$$E_2^{pq} = \mathrm{H}^p(X, \mathrm{R}^q\mathrm{pr}_{1*} j_!\boldsymbol{\mu}_n) = \mathrm{H}^p(X, \mathrm{H}^q_c(X, \boldsymbol{\mu}_n)) \Rightarrow \mathrm{H}^{p+q}(X \times \bar{X}, j_!\boldsymbol{\mu}_n).$$

It degenerates: it is the tensor product of $\mathrm{H}^\bullet(X)$ with the (trivial) Leray spectral sequence for $\bar{X} \to \mathrm{Spec}(k)$ and the sheaf $j_!\boldsymbol{\mu}_n$. Fiber by fiber, the divisor $\Delta - X \times \{0\}$ has degree 0, so the image of e in E^{02} is zero. We may therefore speak of its image $\bar{e}$ in $E^{1,1}$, and we must show that $\bar{e} = -u$.

Let $\mathscr{G}$ on $X \times \bar{X}$ be the subsheaf of $\mathbb{G}_m$ consisting of local sections whose restriction to the closed subscheme $X \times D$ is 1. There is again an exact sequence

$$0 \longrightarrow j_!\boldsymbol{\mu}_n \longrightarrow \mathscr{G} \longrightarrow \mathscr{G} \longrightarrow 0 \tag{3.2.1}$$

and e is the image under ∂ of the class $e_1 \in \mathrm{H}^1(X \times \bar{X}, \mathscr{G})$ of the invertible sheaf $\mathscr{O}(\Delta - X \times \{0\})$, trivialized by 1 on $X \times D$.

Applying $\mathsf{R}\mathrm{pr}_{1*}$ to the distinguished triangle defined by (2.2.1) gives a distinguished triangle

$$\xrightarrow{\partial} \mathsf{R}\mathrm{pr}_{1*}j_!\boldsymbol{\mu}_n \longrightarrow \mathsf{R}\mathrm{pr}_{2*}\mathscr{G} \longrightarrow \mathsf{R}\mathrm{pr}_{2*}\mathscr{G} \xrightarrow{\partial} \tag{3.2.2}$$

and the diagram

$$\begin{array}{ccc} \mathrm{H}^1(X\times\bar{X},\mathscr{G}) & \xrightarrow{\partial} & \mathrm{H}^2(X\times\bar{X},j_!\boldsymbol{\mu}_n) \\ \| (1) & & \| \\ \mathrm{H}^1(X,\mathsf{R}\mathrm{pr}_{1*}\mathscr{G}) & \xrightarrow{\partial} & \mathrm{H}^2(X,\mathsf{R}\mathrm{pr}_{1*}j_!\boldsymbol{\mu}_n) \end{array}$$

is commutative. Our problem is thus to identify the image in $E^{11}=\mathrm{H}^1(X,\mathrm{H}^1_c(X,\boldsymbol{\mu}_n))$ (the image in E^{02} being zero) of the image under $\partial_{(3.2.2)}:\mathrm{H}^1(X,\mathsf{R}\mathrm{pr}_{1*}\mathscr{G})\to\mathrm{H}^2(X,\mathsf{R}\mathrm{pr}_{1*}j_!\boldsymbol{\mu}_n)$ of the class, still denoted by e_1, corresponding to e_1 under (1).

The sheaf $\mathsf{R}^1\mathrm{pr}_{1*}\mathscr{G}$ is defined by the group scheme over X obtained by pulling back the algebraic group $\mathrm{Pic}_D(\bar{X})$ over $\mathrm{Spec}(k)$, and the image of e_1 in $\mathrm{H}^0(X,\mathsf{R}^1\mathrm{pr}_*\mathscr{G})=\hom(X,\mathrm{Pic}_D(\bar{X}))$ is f_0.

Represent the triangle (3.2.2) by a short exact sequence of complexes of sheaves:

$$0\longrightarrow\mathscr{A}\longrightarrow\mathscr{B}\longrightarrow\mathscr{C}\longrightarrow 0.$$

Let $\mathscr{B}'$ be the subsheaf of

$$\tau_{\leqslant 1}\mathscr{B}:\cdots\mathscr{B}^0\to\ker(d)\to 0\cdots$$

obtained by replacing $\mathscr{B}'^1=\ker(d)$ by the inverse image, under $\ker(d)\to\underline{\mathrm{H}}^1(\mathscr{B})=\mathrm{Pic}_D(\bar{X})$ over X, of $\mathrm{Pic}^0_D(\bar{X})$ over X. Let $\mathscr{A}'=\mathscr{A}\cap\mathscr{B}'$ and let $\mathscr{C}'$ be the image of $\mathscr{B}'$. We have $\mathscr{A}'=\tau_{\leqslant 1}(\mathscr{A})$, and $\mathscr{C}'$ is obtained from $\mathscr{C}$ in the same way as $\mathscr{B}'$ from $\mathscr{B}$. Hence there is a commutative diagram of short exact sequences

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathscr{A} & \longrightarrow & \mathscr{B} & \longrightarrow & \mathscr{C} & \longrightarrow & 0 \\ & & \uparrow & & \uparrow & & \uparrow & & \\ 0 & \longrightarrow & \tau_{\leqslant 1}\mathscr{A} & \longrightarrow & \mathscr{B}' & \longrightarrow & \mathscr{C}' & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{H}^1_c(X,\boldsymbol{\mu}_n)[1] & \longrightarrow & \mathrm{Pic}^0_D(\bar{X})[1] & \longrightarrow & \mathrm{Pic}^0_D(\bar{X})[1] & \longrightarrow & 0 \end{array} \tag{3.2.3}$$

where the last row is to be viewed as an exact sequence of complexes of sheaves concentrated in degree 1 on X.

a) $e\in\mathsf{H}^2(X,\mathscr{A})$ comes from $\widetilde{e}\in\mathsf{H}^2(X,\tau_{\leqslant 1}\mathscr{A})$ (because its image in E^{02} is zero). We seek the image $\bar{e}$ of $\widetilde{e}$ in $\mathsf{H}^2(X,\mathrm{H}^1_c(X,\boldsymbol{\mu}_n)[-1])=\mathrm{H}^1(X,\mathrm{H}^1_c(X,\boldsymbol{\mu}_n))$.

b) $e_1\in\mathsf{H}^1(X,\mathscr{C})$ comes from $\widetilde{e}_1\in\mathsf{H}^1(X,\mathscr{C}')$, because its image f_0 in $\mathrm{H}^0(X,\mathrm{Pic}_D(\bar{X}))$ lies in $\mathrm{H}^0(X,\mathrm{Pic}^0_D(\bar{X}))$. We may take $\widetilde{e}=\partial\widetilde{e}_1$.

c) Thus $\bar{e}=\partial f_0$, where ∂ is defined by (3.2.2), and where we use the usual isomorphisms $\mathsf{H}^2(X,\mathscr{F}[-1])=\mathrm{H}^1(X,\mathscr{F})$. These isomorphisms anticommute with ∂, so that $\bar{e}=-\partial f_0$, for ∂ defined by the exact sequence

$$0\longrightarrow\mathrm{H}^1_c(X,\boldsymbol{\mu}_n)\longrightarrow\mathrm{Pic}^0_D(\bar{X})\longrightarrow\mathrm{Pic}^0_D(\bar{X})\longrightarrow 0$$

The conclusion follows from (Cycles, 1.1.1).

3.3

For every homomorphism $\varphi : \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) \to \mathbb{Z}/n$, let $\varphi(u) \in \mathrm{H}^1(X, \mathbb{Z}/n)$ be the image of u under $\varphi : \mathrm{H}^1(X, \mathrm{H}^1_c(X, \boldsymbol{\mu}_n)) \to \mathrm{H}^1(X, \mathbb{Z}/n)$. If $x \in \mathrm{H}^1_c(X, \boldsymbol{\mu}_n)$, the cup product $\varphi(u) \smile x$ lies in $\mathrm{H}^2_c(X, \boldsymbol{\mu}_n)$. We shall prove the following.

Proposition 3.4. $\mathrm{tr}(\varphi(u) \smile x) = \varphi(x)$.

This identity follows, after applying φ, from

$$\mathrm{tr}(u \smile x) = x \tag{3.4.1}$$

where tr now denotes the map

$$\mathrm{tr} : \mathrm{H}^2_c(X, \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) \otimes \boldsymbol{\mu}_n) \longrightarrow \mathrm{H}^1_c(X, \boldsymbol{\mu}_n),$$

so that $x \mapsto \mathrm{tr}(u \smile x)$ is the composite

$$\begin{aligned} &\mathrm{H}^1_c(X, \boldsymbol{\mu}_n) \xrightarrow{u \otimes x} \mathrm{H}^1(X, \mathrm{H}^1_c(X, \boldsymbol{\mu}_n)) \otimes \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) \xleftarrow{\sim} \mathrm{H}^1(X, \mathbb{Z}/n) \otimes \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) \otimes \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) \\ &\xrightarrow{(1)} \mathrm{H}^2_c(X, \boldsymbol{\mu}_n) \otimes \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) \xrightarrow{\mathrm{tr} \otimes \mathrm{id}} \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) \end{aligned} \tag{3.4.2}$$

where (1) is given by $a \otimes b \otimes c \mapsto (a \smile c) \otimes b$.

We express this morphism in terms of the trace morphism $\mathrm{tr} : \mathrm{H}^3_c(X \times X, \boldsymbol{\mu}_n^{\otimes 2}) \to \mathrm{H}^2_c(X, \boldsymbol{\mu}_n)$ relative to the second projection. For $x \in \mathrm{H}^3_c$, $\mathrm{tr}(x)$ is computed as follows: among its Künneth components, retain only the component of type $(2,1)$, and apply $\mathrm{tr} : \mathrm{H}^2_c(X, \boldsymbol{\mu}_n) \to \mathbb{Z}/n$.

Let u' be the image of u under the map

$$\begin{aligned} &\mathrm{H}^1(X, \mathrm{H}^1_c(X, \boldsymbol{\mu}_n)) \xleftarrow{\sim} \mathrm{H}^1(X, \mathbb{Z}/n) \otimes \mathrm{H}^1_c(X, \boldsymbol{\mu}_n) = \mathrm{H}^1(X, \mathbb{Z}/n) \otimes \mathrm{H}^1(\bar{X}, j_!\boldsymbol{\mu}_n) \\ &\longrightarrow \mathrm{H}^2(X \times \bar{X}, \mathbb{Z}/n \boxtimes j_!\boldsymbol{\mu}_n). \end{aligned}$$

In view of the relation between the Künneth formula and cup product, one has

$$\mathrm{tr}(u \smile x) = -\,\mathrm{tr}(u' \smile \mathrm{pr}_1^* x).$$

The second cup product is the one in (Cycle 1.2.4):

$$\mathrm{H}^2(X \times \bar{X}, \mathbb{Z}/n \boxtimes j_!\boldsymbol{\mu}_n) \otimes \mathrm{H}^1(\bar{X} \times \bar{X}, j_!\boldsymbol{\mu}_n \boxtimes \mathbb{Z}/n) \longrightarrow \mathrm{H}^3(\bar{X} \times \bar{X}, j_!\boldsymbol{\mu}_n \boxtimes j_!\boldsymbol{\mu}_n).$$

The minus sign comes from permuting two symbols of degree 1 in (1). Since $c \smile \mathrm{pr}_1^* x$ and $c^{1,1} \smile \mathrm{pr}_1^*$ have the same $(2,1)$-component in the Künneth decomposition, and since $u' = c^{1,1}$, one has

$$\mathrm{tr}(u \smile x) = \mathrm{tr}(c \smile \mathrm{pr}_1^* x).$$

The cup product on the right can now be interpreted as the cup product (Cycle 1.2.5) of $\mathrm{cl}(\Delta) \in \mathrm{H}^2_\Delta(X \times X, \boldsymbol{\mu}_n)$ with $\mathrm{pr}_1^* x \in \mathrm{H}^1_c(\Delta, \boldsymbol{\mu}_n)$. On Δ, one has $\mathrm{pr}_1 = \mathrm{pr}_2$, whence

$$\mathrm{tr}(c \smile \mathrm{pr}_1^* x) = \mathrm{tr}(\mathrm{cl}(\Delta) \smile \mathrm{pr}_1^* x) = \mathrm{tr}(\mathrm{cl}(\Delta) \smile \mathrm{pr}_2^* x) = \mathrm{tr}(\mathrm{cl}(\Delta)) \smile x = x.$$

4 Compatibility with SGA 4 XVIII 3.1.10.3

In [2, XVIII], overcome by discouragement, I did not verify the compatibility announced in the title. Although it turns out to be no more than smoke, I feel bound to remedy that omission here. For $f : X \to S$ separated and of finite type, the point was to verify that the adjunction morphism $\mathsf{R}f_!\mathsf{R}f^!\mathscr{L} \to \mathscr{L}$ is compatible with every étale localization $k : V \to S$. Using k and f for several arrows, as below, we must verify commutativity:

$$\begin{array}{ccc} X_V & \xrightarrow{k} & X \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f} \\ V & \xrightarrow{k} & S \end{array} \qquad \begin{array}{ccc} k^*\mathsf{R}f_!\mathsf{R}f^!\mathscr{L} & \xrightarrow{k^*(\mathrm{adj})} & k^*\mathscr{L} \\ \downarrow{\scriptstyle \sim} & & \| \\ \mathsf{R}f_!\mathsf{R}f^!k^*\mathscr{L} & \xrightarrow{\mathrm{adj}} & k^*\mathscr{L}. \end{array}$$

At the level of complexes, the required commutativity is written (loc. cit.)

$$\begin{array}{ccc} k^*f_!^\bullet f_\bullet^!\mathscr{L} & \longrightarrow & k^*\mathscr{L} \\ \downarrow{\scriptstyle (1)} & & \| \\ f_!^\bullet f_\bullet^! k^*\mathscr{L} & \longrightarrow & k^*\mathscr{L}. \end{array}$$

It is checked component by component, reducing the problem to a compatibility for $\mathscr{L}$ a sheaf and for each pair of adjoint functors $(f_i^!, f_!^i)$, denoted simply by $f^!$ and $f_!$. The arrow (1) is defined using the isomorphism (2) : $k^*f_! = f_!k^*$, and a morphism (3) : $k^*f^! \to f^!k^*$ deduced from it. In loc. cit., one first introduces a morphism (4) : $k_!f_! \to f_!k_!$, deduced from (2) by the adjunction of $k^* = k^!$ and $k_! : k_!f_! \to k_!f_!k^*k_! \to k_!k^*f_!k_! \to f_!k_!$, and then deduces (3) from (4) by adjunction. Equivalently, one may deduce (3) from (2) by the adjunction of $f_!$ and $f^! : k^* \to f^!f_!k^*f^! \to f^!k^*f_!f^! \to f^!k^*$.

Writing k for k^* and omitting $\mathscr{L}$, the required commutativity is that of the outer boundary of

$$\begin{array}{ccccccc} kf_!f^! & \longrightarrow & f_!kf^! & \longrightarrow & f_!f^!f_!kf^! & \longrightarrow & f_!f^!kf_!f^! \\ \| & & & & & & \| \\ kf_!f^! & & \longleftarrow & & \longleftarrow & & f_!f^!kf_!f^! \\ \downarrow & & & & & & \downarrow \\ k & & \longleftarrow & & \longleftarrow & & f_!f^!k. \end{array}$$

In the first row, we find a homomorphism $k_!f^! \to f_!f^!kf_!f^!$, defined because $kf_!f^!$ is of the form $f_!X$ (with $X = kf^!$). It admits the adjunction morphism in the second row as a retraction, and the commutativity of the lower square is the functoriality of this adjunction morphism.

Chapter 6

Applications of the trace formula to trigonometric sums

In this exposé, I explain how the trace formula can be used to calculate or study various trigonometric sums and how, together with the Weil conjecture, it can be used to bound them.

The first two sections provide a "user's guide" to these tools. Section 3 presents, in cohomological language, Weil's results on sums in 1 variable. Sections 4 through 6 give a detailed study of Gauss and Jacobi sums – including Weil's old and recent results on Hecke characters defined by Jacobi sums. In Section 7, we study a generalization of Kloosterman sums to several variables. Finally, Section 8 gives some indications of other uses that have been, or can be, made of these methods.

Notations

0.1

We use the notation of Report, Section 1. We will often have to consider a finite extension $\mathbb{F}_{q^n} \subset \mathbb{F}$ of $\mathbb{F}_q$. A subscript 0 will denote an object over $\mathbb{F}_q$, and a subscript 1 an object over $\mathbb{F}_{q^n}$. Replacing a subscript 0 by a subscript 1 (resp. omitting the subscript) means extending scalars to $\mathbb{F}_{q^n}$ (resp. to $\mathbb{F}$).

0.2

We denote by ℓ a prime number $\neq p$. We freely use the language of $\mathbb{Q}_\ell$-sheaves, as well as that of E_λ-sheaves, where E_λ is a finite extension of $\mathbb{Q}_\ell$ (cf. Report, Section 2, especially 2.11).

0.3

Let $H^\bullet$ be a graded vector space. If T is an endomorphism of $H^\bullet$, we put (cf. Cycle, 1.3.5)

$$\mathrm{tr}(T, H^\bullet) = \sum (-1)^i \,\mathrm{tr}(T, H^i).$$

1 Principles

1.1

Let X_0 be a separated scheme of finite type over $\mathbb{F}_q$, let E_λ be a finite extension of $\mathbb{Q}_\ell$, and let $\mathscr{F}_0$ be an E_λ-sheaf on $X-0$. The trace formula says that

$$\sum_{x\in X^F} \mathrm{tr}(F_x^*,\mathscr{F}) = \sum (-1)^i \,\mathrm{tr}\left(F^*, \mathrm{H}_c^i(X,\mathscr{F})\right). \tag{1.1.1}$$

With the notation 0.3, the right-hand side is simply written $\mathrm{tr}(F^*, \mathrm{H}_c^\bullet(X,\mathscr{F}))$.

This trace formula for E_λ-sheaves can either be deduced from Report 4.10 by passage to the limit (cf. Report 4.11 through 4.13), or be deduced from the trace formula for $\mathbb{Q}_\ell$-sheaves (Report 3.2) by the method of (Functions L mod. ℓ^n, 4.3).

We shall interpret various trigonometric sums as the left-hand side of (1.1.1), for suitable X_0 and $\mathscr{F}_0$.

1.2

Let A be a finite group. An *A-torsor* on a scheme X is a sheaf T on X, equipped with a right action of A, which, locally (for the étale topology) on X, is isomorphic to the constant sheaf A on which A acts by right translation.

If $\tau : A \to B$ is a homomorphism and T is an A-torsor, there exists, up to unique isomorphism, a unique B-torsor $\tau(T)$, equipped with a morphism of sheaves $\tau : T \to \tau(T)$ such that

$$\tau(ta) = \tau(t)\tau(a). \tag{1.2.1}$$

If T is an A-torsor on X and ρ is a linear representation of A, $\rho : A \to \mathrm{GL}(V)$ (where V is a finite-dimensional vector space over E_λ), there exists, up to unique isomorphism, a unique E_λ-sheaf $\mathscr{F}$, smooth of rank $\dim(V)$, equipped with a morphism of sheaves

$$\rho : T \to \underline{\mathrm{Isom}}(V,\mathscr{F}). \tag{1.2.2}$$

such that $\rho(ta) = \rho(t)\rho(a)$. We denote it by $\rho(T)$. For $\tau : A \to B$ and ρ a representation of B, we have a canonical isomorphism $\rho(\tau(T)) = (\rho\tau)(T)$.

In this paragraph (except the appendix), we only consider the case where A is commutative and where $V = E_\lambda$: ρ is a character $A \to E_\lambda^\times$, and $\rho(T)$ is a smooth E_λ-sheaf of rank one. The morphism (1.2.2) is interpreted as an everywhere nonzero morphism

$$\rho : T \to \rho(T) \tag{1.2.3}$$

such that $\rho(ta) = \rho(a)\rho(t)$.

1.3

Let S be a scheme, let G be a commutative group scheme over S, and let G' be an extension of commutative group schemes over S

$$0 \longrightarrow A \longrightarrow G' \xrightarrow{\pi} G \longrightarrow 0.$$

The sheaf T of local sections of π is then an A-torsor on G.

If X is a scheme over S and f, g are two S-morphisms from X to G, the fact that T is defined by an extension gives a canonical isomorphism

$$(f+g)^*T = f^*T + g^*T. \tag{1.3.1}$$

On the left, $f+g$ is the sum of f and g with respect to the group law on G; on the right, $+$ denotes a sum of torsors.

If $f : X \to G$ factors through G', f^*T is trivial (and a factorization gives a trivialization); up to (non-unique) isomorphism, the A-torsor f^*T depends only on the image of f in $\hom_S(X,G)/\pi\hom_S(X,G')$: it is given by the morphism ∂ in the exact sequence

$$\hom(X,G') \longrightarrow \hom(X,G) \xrightarrow{\partial} \mathrm{H}^1(X,A).$$

We will apply these constructions to the exact Kummer sequences $0 \to \boldsymbol{\mu}_n \to \mathbb{G}_m \to \mathbb{G}_m \to 0$, and to Lang torsors.

1.4 The Lang torsor

Let G_0 be a connected commutative algebraic group over $\mathbb{F}_q$ (for the noncommutative case, see the appendix). The group law is written *multiplicatively*. Lang's isogeny

$$\mathfrak{L} : G_0 \to G_0 : x \mapsto Fx \cdot x^{-1}$$

is étale; its image, an open subgroup of G_0, can only be G_0 itself; its kernel is the finite group $G_0(\mathbb{F}_q)$. The *Lang torsor* L is the $G_0(\mathbb{F}_q)$-torsor on G_0 defined by the exact sequence

$$0 \longrightarrow G_0(\mathbb{F}_q) \longrightarrow G_0 \xrightarrow{\mathfrak{L}} G_0 \longrightarrow 0. \tag{1.4.1}$$

Notation We also write L and $\mathfrak{L}$ (or $L_{(q)}$ and $\mathfrak{L}_{(q)}$) for the objects obtained from L and $\mathfrak{L}$ by extending the base field. When necessary, we specify them with a subscript 0 or 1.

Examples For $G_0 = \mathbb{G}_a$ or $\mathbb{G}_m$, the sequences (1.4.1) are written

$$0 \longrightarrow \mathbb{F}_q \longrightarrow \mathbb{G}_a \xrightarrow{x^q - x} \mathbb{G}_a \longrightarrow 0 \tag{1.4.2}$$

$$0 \longrightarrow \boldsymbol{\mu}_{q-1} \longrightarrow \mathbb{G}_m \xrightarrow{x^{q-1}} \mathbb{G}_m \longrightarrow 0 \tag{1.4.3}$$

1.5

Let us compute the endomorphism F^* of the fiber of the Lang torsor at $\gamma \in G^F = G_0(\mathbb{F}_q)$. If $g \in \mathfrak{L}^{-1}(\gamma) \subset G$, we have $Fg = Fg \cdot g^{-1} \cdot g = \gamma g$. Therefore (Report, 1.2)

$$\text{on } L_0(G_0)_\gamma \simeq \mathfrak{L}^{-1}(\gamma),\ F^* \text{ is } g \mapsto g\gamma^{-1}. \tag{1.5.1}$$

1.6

On $\mathbb{F}_{q^n}$, the identity $F_{(q^n)} = F_{(q)}^n$ between endomorphisms of G_1 implies that $\mathfrak{L}_{(q^n)} = \mathfrak{L}_{(q)} \circ \prod_{i=0}^{n-1} F_{(q)}^i$. On $G_0(\mathbb{F}_{q^n})$, $F_{(q)}^i$ acts as the element $x \mapsto x^{q^i}$ of $\mathrm{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q)$. On $G_0(\mathbb{F}_{q^n})$, $\prod F_{(q)}^i$ is therefore the composite of the norm $G_0(\mathbb{F}_{q^n}) \to G_0(\mathbb{F}_q)$ and the inclusion $G_0(\mathbb{F}_q) \subset G_0(\mathbb{F}_{q^n})$: the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & G_0(\mathbb{F}_{q^n}) & \longrightarrow & G_1 & \xrightarrow{\mathfrak{L}_{(q^n)}} & G_1 & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle N} & & \downarrow{\scriptstyle \prod_{i=0}^{n-1} F_{(q)}^i} & & \| & & \\ 0 & \longrightarrow & G_0(\mathbb{F}_q) & \longrightarrow & G_q & \xrightarrow{\mathfrak{L}_{(q)}} & G_1 & \longrightarrow & 0 \end{array} \tag{1.6.1}$$

is commutative. In the language of torsors, this gives a canonical isomorphism between $G_0(\mathbb{F}_q)$-torsors on G_1

$$NL_{(q^n)} = L_{(q)}. \tag{1.6.2}$$

Definition 1.7. *Let $f_0 : X_0 \to G_0$ be a morphism and $\chi : G_0(\mathbb{F}_q) \to E_\lambda^\times$ a character. We set $\mathscr{F}(\chi, f_0) = \chi^{-1}(f_0^*(L_0(G_0))) = f_0^*\chi^{-1}(L_0(G_0))$.*

We have the following functoriality properties:

a) $\mathscr{F}(\chi, f_0)$ is bimultiplicative in χ and f_0:

$$\mathscr{F}(\chi, f_0' \cdot f_0'') = \mathscr{F}(\chi, f_0') \otimes \mathscr{F}(\chi, f_0''), \tag{1.7.1}$$
$$\mathscr{F}(\chi'\chi'', \mathscr{F}_0) = \mathscr{F}(\chi', f_0) \otimes \mathscr{F}(\chi'', f_0). \tag{1.7.2}$$

This follows from the definition of $\chi(T)$, for T a torsor, combined with (1.3.1) for (1.7.1).

b) For $g_0 : Y_0 \to X_0$ a morphism, we have

$$\mathscr{F}(\chi, f_0 \circ g_0) = g_0^*\mathscr{F}(\chi, f_0). \tag{1.7.3}$$

In particular, $\mathscr{F}(\chi, f_0) = f_0^*\mathscr{F}(\chi)$, where $\mathscr{F}(\chi)$ denotes $\mathscr{F}(\chi, \mathrm{id}_{G_0})$.

c) For $u_0 : G_0 \to H_0$ a morphism, and $\chi : H_0(\mathbb{F}_q) \to E_\lambda^\times$, we have

$$\mathscr{F}(\chi, u_0 f_0) = \mathscr{F}(\chi u_0, f_0). \tag{1.7.4}$$

d) For $G_0 = \prod_{i\in I} G_0^i$, with χ having coordinates χ_i ($i \in I$) and f_0 having coordinates f_0^i, it follows from (1.7.1) through (1.7.4) that

$$\mathscr{F}(\chi, f_0) = \bigotimes_{i\in I} \mathscr{F}(\chi_i, f_0^i). \tag{1.7.5}$$

Note the χ^{-1} in Definition 1.7. It ensures that, for $x \in X^F$, on $\mathscr{F}(\chi, f_0)_x$ one has

$$F_x^* = \chi f_0(x) \tag{1.7.6}$$

(use the fact that the fiber at x of the morphism (1.2.2), for $\rho = \chi^{-1}$, commutes with F_x^*, together with (1.5.1)).

If $\mathscr{F}(\chi, f_0)_1$ is the sheaf obtained from $\mathscr{F}(\chi, f_0)$ by extension from the base field to $\mathbb{F}_{q^n}$, we deduce from (1.6.2) that

$$\mathscr{F}(\chi, f_0)_1 = \mathscr{F}(\chi \circ N, f_1). \tag{1.7.7}$$

1.8 Abuse of notations

(i) If Ξ denotes the composite map $\chi f_0 : X_0(\mathbb{F}_q) \to E_\lambda^\times$, we will sometimes write $\mathscr{F}(\Xi)$ instead of $\mathscr{F}(\chi, f_0)$. By (1.7.1) through (1.7.5), there is little risk of ambiguity. For example:

a) we write $\mathscr{F}(\chi)$ for $\mathscr{F}(\chi, \mathrm{id}_{G_0})$ (notation already used in 1.7b));

b) we write $\mathscr{F}(\chi f_0)$ for $\mathscr{F}(\chi, f_0)$;

c) with the notation of 1.7d), we write $\mathscr{F}(\prod \chi_i f_0^i)$ for $\mathscr{F}(\chi, f)$).

With this notation, (1.7.4) shows that the notation $\mathscr{F}(\chi u_0 f_0)$ is unambiguous, (1.7.1) (1.7.2) (1.7.5) express the multiplicativity of $\mathscr{F}(\Xi)$ with respect to Ξ, and (1.7.6) becomes $F_x^* = \Xi(x)$ on $\mathscr{F}(\Xi)_x$.

(ii) If X is a scheme over an extension k of $\mathbb{F}_q$, and f is a morphism of X into $G_0 \otimes_{\mathbb{F}_q} k$, we shall again denote by $\mathscr{F}(\chi, f)$, $\mathscr{F}(\chi f)$, or $\mathscr{F}(\chi)$ (for f an inclusion) the inverse image under f of the E_λ-sheaf obtained from $\chi^{-1}(L_0(G))$ by extension of scalars from $\mathbb{F}_q$ to k. If f_0 is the composite $X \to G_0 \otimes_{\mathbb{F}_q} k \to G_0$, this is again the $\mathscr{F}(\chi, f_0)$ of 1.7. If k is a finite extension of $\mathbb{F}_q$, we have $\mathscr{F}(\chi f) = \chi(\chi N_{k/\mathbb{F}_q} f)$.

Applying (1.1.1) to (1.7.6) and (1.7.7), we find:

Theorem 1.9. *Let S_0 be a separated scheme of finite type over $\mathbb{F}_q$, let G_0 be a connected commutative algebraic group over $\mathbb{F}_q$, let $f_0 : S_0 \to G_0$ be a morphism, and let $\chi : G_0(\mathbb{F}_q) \to E_\lambda^\times$. We have*

$$\sum_{s \in S_0(\mathbb{F}_q)} \chi f_0(s) = \mathrm{tr}(F^*, \mathrm{H}_c^\bullet(S, \mathscr{F}(\chi, f_0))) \tag{1.9.1}$$

and, for any integer $n \geqslant 1$,

$$\sum_{s \in S_0(\mathbb{F}_{q^n})} \chi \circ N_{\mathbb{F}_{q^n}/\mathbb{F}_q} f_0(s) = \mathrm{tr}(F^{*n}, \mathrm{H}_c^\bullet(S, \mathscr{F}(\chi, f_0))) \,. \tag{1.9.2}$$

1.9.3 Remark

Take G_0 to be a product. With the notation of 1.7d) and 1.8c), the formula (1.9.2) becomes

$$\sum_{s \in S_0(\mathbb{F}_{q^n})} \prod_i \chi_i \circ N_{\mathbb{F}_{q^n}/\mathbb{F}_q}(f_0^i(s)) = \mathrm{tr}\left(F^{*n}, \mathrm{H}_c^\bullet\left(S, \mathscr{F}\Big(\prod_i \chi_i f_0^i\Big)\right)\right).$$

1.9.4 Remark

Take $G_0 = \{e\}$. Formula (1.9.1) becomes

$$|S_0(\mathbb{F}_q)| = \sum_{s \in S_0(\mathbb{F}_q)} 1 = \mathrm{tr}(F^*, \mathrm{H}_c^\bullet(S, \mathbb{Q}_\ell)).$$

It is rare to be able to compute the right-hand side of (1.9.1) explicitly. Here is an amusing example, with $G_0 = \{e\}$.

1.10 Example

A nonsingular projective quadric of odd dimension over $\mathbb{F}_q$ has the same number of rational points as projective space of the same dimension over $\mathbb{F}_q$.

If, over $\mathbb{C}$, X is a nonsingular quadric hypersurface in the projective space $\mathbb{P}^{2N}$, and Y a hyperplane, we know that for $i \leqslant 2\dim(X) = 2\dim(Y)$, the inclusions $X \hookrightarrow \mathbb{P}^{2N} \hookleftarrow Y$ induce isomorphisms (in ordinary cohomology)

$$\mathrm{H}^i(X, \mathbb{Q}) \xleftarrow{\sim} \mathrm{H}^i(\mathbb{P}^{2N}, \mathbb{Q}) \xrightarrow{\sim} \mathrm{H}^i(Y, \mathbb{Q}).$$

By specialization, it follows that if X_0' is a nonsingular quadric hypersurface in projective space $\mathbb{P}_0^{2N}$ over $\mathbb{F}_q$, and Y_0' a hyperplane, the inclusions $X_0' \hookrightarrow \mathbb{P}_0^{2N} \hookleftarrow Y_0'$ induce isomorphisms

$$\mathrm{H}^i(X', \mathbb{Q}_\ell) \xleftarrow{\sim} \mathrm{H}^i(\mathbb{P}^{2N}, \mathbb{Q}_\ell) \xrightarrow{\sim} \mathrm{H}^i(Y', \mathbb{Q}_\ell).$$

These isomorphisms commute with F^*, and the trace formula applies.

1.11

The trace formula can also be used to understand the classical formulas giving the number of rational points of linear groups over finite fields, and of certain homogeneous spaces (see Section 8).

1.12

There is a dictionary that translates various kinds of classical manipulations of trigonometric sums into cohomological terms. This dictionary will be given in Section 2. Since the cohomological statement is more "geometric," it can sometimes be applied to situations where the classical argument only applies after a extension of the finite base field. Here is an example (a special case of a theorem of Kazhdan).

Theorem 1.13 (Kazhdan)**.** *Let X_0 be a scheme over $\mathbb{F}_q$. Suppose there is an action ρ of $\mathbb{G}_a$ on X, and a morphism $f : X \to Y$ of schemes over $\mathbb{F}$, making X a $\mathbb{G}_a$-torsor over Y. Then the number of rational points of X_0 is divisible by q.*

First suppose that ρ, Y, and f are defined over $\mathbb{F}_q$.

Classical argument The fibers of $f : X_0(\mathbb{F}_q) \to Y_0(\mathbb{F}_q)$ all have q elements: $|X_0(\mathbb{F}_q)| = q \cdot |Y_0(\mathbb{F}_q)|$, hence the divisibility.

Cohomological translation The higher direct image sheaves $\mathsf{R}^i f_! \mathbb{Q}_\ell$ are

$$\mathsf{R}^i f_! \mathbb{Q}_\ell = \begin{cases} \mathbb{Q}_\ell(-1) & \text{if } i = 2 \\ 0 & \text{for } i \neq 2 \end{cases}$$

The Leray spectral sequence for f therefore degenerates, giving an isomorphism

$$\mathrm{H}_c^i(X, \mathbb{Q}_\ell) = \mathrm{H}_c^{i-2}(Y, \mathbb{Q}_\ell)(-1).$$

To understand the effect of a Tate twist on the eigenvalues of Frobenius, it is most convenient to use the Galois point of view (Report 1.8) and note that the Frobenius substitution φ acts on $\mathbb{Q}_\ell(1)$ by multiplication by q. The eigenvalues of F^* on $\mathrm{H}_c^p(X, \mathbb{Q}_\ell)$ are therefore obtained by multiplying by q the

eigenvalues of F^* acting on $\mathrm{H}_c^{i-2}(Y, \mathbb{Q}_\ell)$. We know that the latter are algebraic integers [16, XXI 5.2.2]; hence

$$\begin{gathered}\text{the eigenvalues of } F^* \text{ acting on } \mathrm{H}_c^i(X, \mathbb{Q}_\ell) \text{ are} \\ \text{algebraic integers divisible by } q.\end{gathered} \tag{$*$}$$

Descent Return to the hypotheses of the theorem. For a suitable n, we may suppose that ρ, Y, and f are defined over $\mathbb{F}_{q^n}$. Since the Frobenius morphism relative to $\mathbb{F}_{q^n}$ is the n-th power of the one relative to $\mathbb{F}_q$, statement $(*)$ for the scheme over $\mathbb{F}_{q^n}$ obtained from X_0 by extension of scalars gives:

$$\begin{gathered}\text{the } n\text{-th powers of the eigenvalues of } F^* \text{ acting on} \\ \mathrm{H}_c^i(X, \mathbb{Q}_\ell) \text{ are algebraic integers divisible by } q^n.\end{gathered} \tag{$**$}$$

This assertion implies $(*)$. The number of rational points of X_0, namely $\sum(-1)^i \operatorname{tr}(F^*, \mathrm{H}^i(X, \mathbb{Q}_\ell))$, is therefore an algebraic integer divisible by q. It follows that, as a rational integer, it is divisible by q.

1.14

Formula 1.9.3 controls the dependence on n of the trigonometric sum on the left-hand side. It implies identities between a trigonometric sum and those which are deduced from it by "extension of scalars." The most famous of these identities is that of Hasse–Davenport. Let $\chi : \mathbb{F}_q^\times \to \mathbb{C}^\times$ and $\psi : \mathbb{F}_q \to \mathbb{C}^\times$ be characters, with ψ nontrivial, and define the Gauss sum $\tau(\chi, \psi)$ by

$$\tau(\chi, \psi) = -\sum_{x \in \mathbb{F}_q^\times} \psi(x)\chi^{-1}(x). \tag{1.14.1}$$

Theorem 1.15 (Hasse-Davenport)**.** *We have*

$$\tau\left(\chi \circ N_{\mathbb{F}_{q^n}/\mathbb{F}_q}, \psi \circ \operatorname{tr}_{\mathbb{F}_{q^n}/\mathbb{F}_q}\right) = \tau(\chi, \psi)^n. \tag{1.15.1}$$

Let $E \subset \mathbb{C}$ be a number field containing the values of χ and ψ, and let E_λ be the completion of E at a place of residue characteristic $\ell \neq p$. Identity (1.15.1) is an identity in E. Proving it in $\mathbb{C}$ is equivalent to proving it in E_λ. We shall prove it in E_λ, regarding χ and ψ as taking values in $E_\lambda^\times$.

Apply 1.9.3 with $X_0 = \mathbb{G}_m$ over $\mathbb{F}_q$ and $G_0 = \mathbb{G}_m \times \mathbb{G}_a$. The groups $\mathrm{H}_c^i(\mathbb{G}_m, \mathscr{F}(\chi^{-1}\psi))$ vanish for $i \neq 1$, and H_c^1 has dimension 1 (4.2). By 1.9.3, $\tau(\chi \circ N_{\mathbb{F}_{q^n}/\mathbb{F}_q}, \psi \circ \operatorname{tr}_{\mathbb{F}_{q^n}/\mathbb{F}_q})$ is the unique eigenvalue of $(F^*)^n$ on H_c^1, and (1.15.1) follows.

Similar examples are given in Weil [43, App V].

1.16

An E_λ-sheaf $\mathscr{F}_0$ on $X - 0$ is said to be *pointwise pure of weight* n if for any closed point $x \in |X_0|$, the eigenvalues of F_x^* (Report 1.2) are algebraic numbers all of whose complex conjugates have absolute value $q_x^{n/2}$, where q_x is the number of elements of $k(x)$. The following theorem will be proved in [15].

Theorem 1.17. *If $\mathscr{F}_0$ is pointwise pure of weight n, then for any eigenvalue α of the endomorphism F^* of $\mathrm{H}_c^i(X, \mathscr{F})$, there exists an integer $m \leqslant n + i$ such that the complex conjugates of α are all of absolute value $q^{m/2}$.*

The sheaves considered in 1.9 have weight 0. The theorem therefore gives, for the sum 1.9.1 (or rather, for all its complex conjugates), the bound

$$\left|\sum_{s\in S_0(\mathbb{F}_q)}\prod_i \chi_i(f^i(s))\right| \leqslant \sum_i \dim \mathrm{H}^i_c\left(S, \mathscr{F}\left(\prod \chi_i f^i\right)\right)\cdot q^{i/2}. \tag{1.17.1}$$

1.18 Remarks

a) If $\dim S = n$, for any E_λ-sheaf $\mathscr{F}$ on S, we have

$$\mathrm{H}^i_c(S,\mathscr{F}) = 0 \qquad \text{for } i \notin [0,2n].$$

b) The group $\mathrm{H}^0_c(X,\mathscr{F})$ is the group of global sections of $\mathscr{F}$ on S whose support is proper. If S is connected, not proper and $\mathscr{F}$ is smooth, this group is zero; the same holds if S is connected, $\mathscr{F}$ is smooth of rank one, and is nonconstant.

c) If S is smooth and purely of dimension n, and $\mathscr{F}$ is smooth, Poincaré duality says that the vector spaces $\mathrm{H}^i_c(X,\mathscr{F})$ and $\mathrm{H}^{2n-i}(X,\mathscr{F}^\vee)(2n)$ are dual to each other (for the effect of a Tate twist on the eigenvalues of Frobenius, cf. the 2nd part of the proof of 1.13).

d) If $\dim S = n$, Poincaré duality allows us to compute $\mathrm{H}^{2n}_c(S,\mathscr{F})$ as follows: take an open subset U of S_{red} whose complement has dimension $< n$; require this open subset to be smooth and purely of dimension n, with $\mathscr{F}$ smooth on it. We then have $\mathrm{H}^{2n}_c(U,\mathscr{F}) \xrightarrow{\sim} \mathrm{H}^{2n}_c(S,\mathscr{F})$, because in the long exact sequence of cohomology, $\mathrm{H}^i_c(S\smallsetminus U,\mathscr{F}) = 0$ for $i = 2n, 2n-1$. Poincaré duality therefore gives

$$\mathrm{H}^{2n}_c(S,\mathscr{F}) \xrightarrow{\sim} \left(\mathrm{H}^0(U,\mathscr{F}^\vee)(2n)\right)^\vee.$$

Let U be connected, and let u be a geometric point of U. The "local system" $\mathscr{F}$ corresponds to a representation of $\pi_1(U,u)$ on $\mathscr{F}_u$, and $\mathrm{H}^0(U,\mathscr{F}^\vee)$ is $(\mathscr{F}_u^\vee)^{\pi_1(U,u)} = ((\mathscr{F}_u)_{\pi_1(U,u)})^\vee$ (dual of coinvariants). We therefore have

$$\mathrm{H}^{2n}_c(S,\mathscr{F}) \simeq (\mathscr{F}_u)_{\pi_1(U,u)}(-2n).$$

e) These remarks often allow the calculation of b_0 and b_{2n}. Computing the other b_i can be difficult. If $b_{2n} = 0$ and $b_{2n-1} = 0$, the bound (1.17.1) is a Lang–Weil bound, with, for large q, a gain of $\sqrt{q}$ over the trivial $O(q^n)$ bound. One should bear in mind, however, that (1.17.1) does not formally imply the trivial bound

$$\left|\sum_{s\in S_0(\mathbb{F}_q)}\prod_i \chi_i(f^i(s))\right| \leqslant \left|S_0(\mathbb{F}_q)\right|,$$

so it may be useful to take this into account (cf. the proof of 3.8).

Below I explain a method for proving that $b_i = 0$ for $i \neq n$. When it applies, it gives an estimate of order $O(q^{n/2})$. The constant implicit in 0 is $b_n = (-1)^n\chi(S,\mathscr{F}(\prod \chi_i f^i))$, which may be difficult to compute.

Proposition 1.19. *Let $\bar{X}$ be a proper scheme over an algebraically closed field k, let $j : X \hookrightarrow barX$ be an open immersion with domain X, and let $\mathscr{F}$ be an E_λ-sheaf on X. Assume that*

a) $(j_*\mathscr{F})_x = 0$ for $x \in \bar{X}\smallsetminus X$, i.e. $j_!\mathscr{F} \xrightarrow{\sim} j_*\mathscr{F}$;

b) $\mathsf{R}^i j_* \mathscr{F} = 0$ *for* $i > 0$.

Then the maps

$$\mathrm{H}^i_c(X, \mathscr{F}) \to \mathrm{H}^i(X, \mathscr{F})$$

are isomorphisms.

Assumptions a) and b) mean that $j_! \mathscr{F} \xrightarrow{\sim} \mathsf{R} j_* \mathscr{F}$, hence

$$\mathrm{H}^i_c(X, \mathscr{F}) = \mathrm{H}^i(\bar{X}, j_! \mathscr{F}) \xrightarrow{\sim} \mathsf{H}^i(\bar{X}, \mathsf{R} j_* \mathscr{F}) = \mathrm{H}^i(X, \mathscr{F}).$$

In other words, the Leray spectral sequence for j

$$E_2^{pq} = \mathrm{H}^p(\bar{X}, \mathsf{R}^q j_* \mathscr{F}) \Rightarrow \mathrm{H}^{p+q}(X, \mathscr{F})$$

degenerates, by b) into isomorphisms

$$\mathrm{H}^i(\bar{X}, j_* \mathscr{F}) \xrightarrow{\sim} \mathrm{H}^i(X, \mathscr{F}),$$

while, by a)

$$\mathrm{H}^i_c(X, \mathscr{F}) = \mathrm{H}^i(\bar{X}, j_! \mathscr{F}) \xrightarrow{\sim} \mathrm{H}^i(\bar{X}, j_* \mathscr{F}).$$

1.19.1 Example

If X is a curve, or if $\bar{X}$ is smooth, X is the complement of a normal-crossings divisor, and $\mathscr{F}$ is tamely ramified, hypothesis a) of 1.19 (no invariants under local monodromy) implies hypothesis b).

Proposition 1.20. *Let X_0 be a smooth affine scheme, purely of dimension n, over $\mathbb{F}_q$, and let $\mathscr{F}_0$ be a smooth E_λ-sheaf, pointwise pure of weight m, on X_0. We assume that the maps $\mathrm{H}^i_c(X, \mathscr{F}) \to \mathrm{H}^i(X, \mathscr{F})$ are isomorphisms (cf. 1.17). Then, $\mathrm{H}^i_c(X, \mathscr{F}) = 0$ for $i \neq n$, and the complex conjugates of the eigenvalues of F^* on $\mathrm{H}^n_c(X, \mathscr{F})$ are of absolute value $q^{(m+n)/2}$.*

Poincaré duality pairs $\mathrm{H}^i_c(X, \mathscr{F})$ (resp. $\mathrm{H}^i_c(X, \mathscr{F}^\vee)$) with $\mathrm{H}^{2n-i}(X, \mathscr{F}^\vee(n))$ (resp. $\mathrm{H}^{2n-i}(X, \mathscr{F}(n))$). According to [2, XIV 3.2], the ordinary H^i groups vanish for $i > n$. By duality, the H^i_c are zero for $i < n$; since $\mathrm{H}^i_c(X, \mathscr{F}) \xrightarrow{\sim} \mathrm{H}^i(X, \mathscr{F})$, these groups are zero for $i \neq n$. Apply 1.15 to $\mathscr{F}_0$ and to $\mathscr{F}_0^\vee(n)$ (of weight $-m-2n$). We find that the complex conjugates α of the eigenvalues of F^* on $\mathrm{H}^n_c(X, \mathscr{F}) = \mathrm{H}^n_c(X, \mathscr{F}^\vee(n))^\vee$ satisfy

$$|\alpha| \leqslant q^{(m+n)/2} \qquad \text{and}$$
$$|\alpha^{-1}| \leqslant q^{((-m-2n)+n)/2} = q^{-(m+n)/2},$$

hence the assertion.

1.21 Remark

The last argument shows that if X_0 is a smooth separated scheme over $\mathbb{F}_q$, if $\mathscr{F}_0$ is a smooth E_λ-sheaf pointwise pure of weight m on X_0, and if $\mathrm{H}^i_c(X, \mathscr{F}) \hookrightarrow \mathrm{H}^i(X, \mathscr{F})$, then the complex conjugates of the eigenvalues of F^* on $\mathrm{H}^i_c(X, \mathscr{F})$ are of absolute value $q^{(m+i)/2}$.

Appendix. The Lang isogeny in the noncommutative case

1.22

Let $G-0$ be a connected algebraic group over $\mathbb{F}_q$ and let $\mathfrak{L}$ be the morphism $x \mapsto Fx \cdot x^{-1}$ from $G-0$ to itself. It is a morphism of G_0-homogeneous spaces if, on the source, $G-0$ acts by left translation $x \mapsto (y \mapsto xy)$, and on the target by $x \mapsto (y \mapsto Fx \cdot y \cdot x^{-1})$. We have $\mathfrak{L}(xy) = \mathfrak{L}(x)$ for $y \in G_0(\mathbb{F}_q)$, and $\mathfrak{L}$ induces an isomorphism $G_0/G_0(\mathbb{F}_q) \xrightarrow{\sim} G_0$.

As in the commutative case, $\mathfrak{L}$ therefore makes G_0 a $G_0(\mathbb{F}_q)$-torsor on G_0, the *Lang torsor* L. If $\rho : G_0(\mathbb{F}_q) \to \mathrm{GL}(n, E_\lambda)$ is a linear representation of $G_0(\mathbb{F}_q)$, we denote by $\mathscr{F}(\rho)$ the E_λ-sheaf $\rho(L)$ (1.2).

1.23

Let $\gamma \in G^F = G_0(\mathbb{F}_q)$, and compute the endomorphism F^* of $\mathscr{F}(\rho)_\gamma$. Let $g \in G$ be such that $\mathfrak{L}(g) = \gamma$, and choose the frame $\rho(g) \in \mathrm{Isom}(E_\lambda^n, \mathscr{F}(\rho)_\gamma)$. For $e \in E_\lambda^n$, we have

$$F(\rho(g)(e)) = \rho(Fg)(e) = \rho(\gamma g)(e) = \rho(g \cdot g^{-1}\gamma g)(e).$$

We will see that $g^{-1}\gamma g \in G_0(\mathbb{F}_q)$, hence

$$F(\rho(g)(e)) = \rho(g)\rho(g^{-1}\gamma g)(e)$$

and

$$\rho(g)^{-1}(F_\gamma^*)^{-1}\rho(g) = \rho(g^{-1}\gamma g): \tag{1.23.1}$$

$\rho(g)$ identifies the inverse of F^* at γ with the automorphism $\rho(g^{-1}\gamma g)$ of E_λ^n. It remains to understand $g^{-1}\gamma g$.

Lemma 1.24. *(i) If $Fg \cdot g^{-1} \in G_0(\mathbb{F}_q)$, we have $g^{-1}(Fg \cdot g^{-1})g = g^{-1}Fg \in G_0(\mathbb{F}_q)$.*

(ii) Let $\gamma \in G_0(\mathbb{F}_q)$, and g such that $Fg \cdot g^{-1} = \gamma$. The conjugation class of $\gamma' = g^{-1}Fg$ in $G_0(\mathbb{F}_q)$ only depends on that of γ.

(iii) The map induced by $\gamma \mapsto \gamma'$ on the set $G_0(\mathbb{F}_q)^\natural$ of conjugacy classes of $G_0(\mathbb{F}_q)$ is bijective. Its inverse is the corresponding map for the opposite group.

(i) If $\gamma = Fg \cdot g^{-1} \in G_0(\mathbb{F}_q)$, the identities $Fg = \gamma g$ and $F\gamma = \gamma$ give $F(g^{-1}Fg) = (Fg)^{-1}FFg = g^{-1}\gamma^{-1}F(\gamma g) = g^{-1}\gamma^{-1}F\gamma Fg = g^{-1}Fg$, so that $g^{-1}Fg \in G_0(\mathbb{F}_q)$.

(ii) For $\alpha, \gamma \in G_0(\mathbb{F}_q)$, the g such that $Fg \cdot g^{-1} = \gamma$ form a right coset under $G_0(\mathbb{F}_q)$, and if $Fg \cdot g^{-1} = \gamma$, we have $F(\alpha g \alpha^{-1})(\alpha g \alpha^{-1})^{-1} = \alpha\gamma\alpha^{-1}$. As γ ranges over a conjugacy class in $G_0(\mathbb{F}_q)$, the g such that $Fg \cdot g^{-1} = \gamma$ therefore range over a double coset under $G_0(\mathbb{F}_q)$, and $\gamma' = g^{-1}Fg$ ranges over a conjugacy class.

(iii) Finally, the inverse of $Fg \cdot g^{-1} \mapsto g^{-1}Fg$ is $g^{-1}Fg \mapsto Fg \cdot g^{-1}$.

1.25

Formula (1.23.1) can be read succinctly: F^* at γ is $\rho(\gamma')^{-1}$. If γ belongs to the identity component of its centralizer, we can take g in $Z(\gamma)$. We then have $\gamma = \gamma'$. If this condition is not met, γ and γ' need not be conjugate.

1.26 An example

For $G_0 = \mathrm{SL}(2)$, q odd, $\alpha \in F_q^\times \smallsetminus \mathbb{F}_q^{\times 2}$, and $\bar\gamma$ is the conjugacy class of $-1(1+N)$, with $N^2 = 0$, then $\bar\gamma'$ is the conjugacy class of $-1 \cdot (1+\alpha N)$, so that $\bar\gamma' \neq \bar\gamma$ if $N \neq 0$.

2 Dictionary

Elementary manipulations of trigonometric sums can often be seen, via the trace formula, as counterparts of statements in cohomology. In this section, I list such statements and their counterparts; they carry the same number, with a $*$ appended to the cohomological statement.

2.1

"A sum of algebraic integers is an algebraic integer" has as its cohomological analogue the following theorem, proved in [16, XXI 5.2.2] (see the use of 2.1* in 1.13).

Theorem (2.1*)**.** *Let X_0 be a separated scheme of finite type over $\mathbb{F}_q$ and let $\mathscr{F}_0$ be an E_λ-sheaf on X_0. If, for all $x \in |X_0|$, the eigenvalues of F_x^* on $\mathscr{F}_0$ are algebraic integers, then the eigenvalues of F^* on $\mathrm{H}_c^i(X, \mathscr{F})$ are algebraic integers.*

2.2

Other integrality results are proved in [16, XXI, 5.2.2 et 5.4]: if $\dim(x_0) \leqslant n$, and α is an eigenvalue of F^* on $\mathrm{H}_c^i(X, \mathscr{F})$, we have:

a) under the assumptions of 2.1*, and if $i > n$, then q^{i-n} divides α;

b) if the inverses of the eigenvalues of F_x^* are algebraic integers, then α^{-1} is integral away from p. More precisely, $q^{\inf(n,i)}\alpha^{-1}$ is an algebraic integer.

For the sheaves considered in 1.9, the eigenvalues of F_x^* are roots of unity, so the assumptions of the theorem and of b) above are satisfied.

2.3

Let $f : A \to B$ be a map from one finite set to another, and ε a function on A. We have

$$\sum_{a \in A} \varepsilon(a) = \sum_{b \in B} \sum_{f(a)=b} \varepsilon(a). \tag{2.3.1}$$

2.3*

Let $f : X \to Y$ be a morphism of separated schemes of finite type over an algebraically closed field k, and let $\mathscr{F}$ be an E_λ-sheaf on X. The Leray spectral sequence for f in cohomology with compact support is

$$E_2^{pq} = \mathrm{H}_c^p(Y, \mathsf{R}^q f_! \mathscr{F}) \Rightarrow \mathrm{H}_c^{p+q}(X, \mathscr{F}). \tag{2.3.1*}$$

Let $f_0 : X_0 \to Y_0$ be a morphism of separated schemes of finite type over $\mathbb{F}_q$ and let $\mathscr{F}_0$ be an E_λ-sheaf on X_0. Between (2.3.1) and (2.3.1*) there is the following compatibility.

a) The sheaf $\mathsf{R}^q f_!\mathscr{F}$ is obtained by extending scalars from $\mathbb{F}_q$ to $\mathbb{F}$ in the sheaf $\mathsf{R}^q f_{0!}\mathscr{F}_0$ on Y_0. As such, it is equipped with a Frobenius correspondence $F^* : F^*\mathsf{R}^q f_!\mathscr{F} \to \mathsf{R}^q f_!\mathscr{F}$. It is obtained by applying the functoriality of $\mathsf{R}f_!$ to the Frobenius correspondence of $\mathscr{F}$: namely the composite

$$F^*\mathsf{R}^q f_!\mathscr{F} \xrightarrow{\sim} \mathsf{R}^q f_! F^*\mathscr{F} \xrightarrow{\sim} \mathsf{R}^q f_!\mathscr{F}.$$

b) The trace formula for $\mathscr{F}_q$ reads

$$\sum_{x\in X_0(\mathbb{F}_q)} \operatorname{tr}(F_x^*, \mathscr{F}_0) = \operatorname{tr}(F^*, \mathrm{H}^\bullet(X, \mathscr{F})); \tag{1}$$

while that for $\mathsf{R}^q f_!\mathscr{F}$ reads

$$\sum_{y\in Y_0(\mathbb{F}_q)} \operatorname{tr}(F_y^*, \mathsf{R}^q f_!\mathscr{F}) = \operatorname{tr}(F^*, \mathrm{H}^\bullet(Y, \mathsf{R}^q f_!\mathscr{F})). \tag{2_q}$$

We have, for $y \in Y(\mathbb{F})$, $(\mathsf{R}^q f_!\mathscr{F})_y = \mathrm{H}_c^q(f^{-1}(y), \mathscr{F})$, and if $y \in Y_0(\mathbb{F}_q)$,

$$\operatorname{tr}(F_y^*, \mathsf{R}^q f_!\mathscr{F}) = \operatorname{tr}(F^*, \mathrm{H}_c^q(f^{-1}(y), \mathscr{F})),$$

hence by the trace formula on the fiber

$$\sum_{\substack{x\in X_0(\mathbb{F}_q)\\ f(x)=y}} \operatorname{tr}(F_x^*, \mathscr{F}_0) = \sum (-1)^q \operatorname{tr}(F_y^*, \mathsf{R}^q f_!\mathscr{F}).$$

Taking the alternating sum of the identities (2_q), we therefore find

$$\sum_{y\in Y_0(\mathbb{F}_q)} \sum_{\substack{x\in X_0(\mathbb{F}_q)\\ f(x)=y}} \operatorname{tr}(F_x^*, \mathscr{F}_0) = \operatorname{tr}(F^*, \mathrm{H}^\bullet(Y, \mathsf{R}^\bullet f_!\mathscr{F})). \tag{2}$$

Equality of the left-hand sides of (1) and (2) follows from (2.3.1); equality of the right-hand sides follows from (2.3.1*) (taking into account that F^* is an endomorphism of the entire spectral sequence).

2.4

Let $(A_i)_{i\in I}$ be a finite family of finite sets, $A = \prod_{i\in I} A_i$, ε_i a function on A_i, and ε the function $a \mapsto \prod \varepsilon_i(a_i)$ on A. We have

$$\sum_{a\in A} \varepsilon(a) = \prod_{i\in I} \sum_{a_i\in A_i} \varepsilon_i(a_i). \tag{2.4.1}$$

2.4*

Let $(X_i)_{i\in I}$ be a finite family of separated schemes of finite type over an algebraically closed field k, let $X = \prod_{i\in I} X_i$, let $\mathscr{F}_i$ be an E_λ-sheaf on X_i and $\mathscr{F}$ the external tensor product $\boxtimes_{i\in I} \mathscr{F}_i = \bigotimes_{i\in I} \mathrm{pr}_i^*(\mathscr{F}_i)$ of the $\mathscr{F}_i$. The Künneth formula gives

$$\mathrm{H}_c^\bullet(X, \mathscr{F}) = \bigotimes_{i\in I} \mathrm{H}_c^\bullet(X_i, \mathscr{F}_i). \tag{2.4.1*}$$

For the isomorphism (2.4.1*) to be canonical and independent of the choice of a total ordering of I, the tensor product on the right must be understood as a graded tensor product, with the Koszul sign rule (Cycle, 1.3).

2.5

Let A be a finite set, let B be a subset of A, and let ε be a function on A. We have

$$\sum_{a\in A}\varepsilon(a)=\sum_{a\in A\smallsetminus B}\varepsilon(a)+\sum_{a\in B}\varepsilon(a). \tag{2.5.1}$$

2.5*

Let x be a separated scheme of finite type over an algebraically closed field k, let Y be a closed subscheme, and let $\mathscr{F}$ be an E_λ-sheaf on X. We have a long exact cohomology sequence

$$\cdots\xrightarrow{\partial}\mathrm{H}^i_c(X\smallsetminus Y,\mathscr{F})\longrightarrow\mathrm{H}^i_c(X,\mathscr{F})\longrightarrow\mathrm{H}^i_c(Y,\mathscr{F})\xrightarrow{\partial}\cdots \tag{2.5.1*}$$

More generally, given a finite filtration of X by closed subsets X_p ($p\in\mathbb{Z}$; assume that $X_p\supset X_{p+1}$, that $X_p=X$ for p sufficiently small, and that $X_p=\varnothing$ for p sufficiently large), there is a spectral sequence

$$E_1^{pq}=\mathrm{H}^{p+1}_c(X_p\smallsetminus X_{p+1},\mathscr{F})\Rightarrow\mathrm{H}^{p+q}_c(X,\mathscr{F}). \tag{2.5.2*}$$

2.6

Let A be a finite set, $(A_i)_{i\in I}$ a finite covering of A and ε a function on A. For $J\subset I$, denote by A_J the intersection of A_j ($j\in J$). We have

$$\sum_{J\subset I}(-1)^{|J|}\sum_{a\in A_J}\varepsilon(a)=0. \tag{2.6.1}$$

2.6*

Let X be a separated scheme of finite type over an algebraically closed field k, $(X_i)_{i\in I}$ a closed (resp. open) finite covering of X by subschemes, and $\mathscr{F}$ an E_λ-sheaf on X. For $J\subset I$, let X_J be the intersection of the X_j ($j\in J$). We have the respective Leray spectral sequences

$$E_1^{pq}=\bigoplus_{|J|=p+1>0}\mathrm{H}^q_c(X_J,\mathscr{F})\otimes_{\mathbb{Z}}\bigwedge^{|J|}\mathbb{Z}^J\Rightarrow\mathrm{H}^{p+q}_c(X,\mathscr{F}) \tag{2.6.1*}$$

$$E_1^{pq}=\bigoplus_{|J|=1-p>0}\mathrm{H}^q_c(X_J,\mathscr{F})\otimes_{\mathbb{Z}}\bigwedge^{|J|}\mathbb{Z}^J\Rightarrow\mathrm{H}^{p+q}_c(X,\mathscr{F}) \tag{2.6.2*}$$

If $J=\varnothing$ were not excluded, there would also be spectral sequences converging to 0. The factors $\bigwedge^{|J|}\mathbb{Z}^J$ are included to avoid choosing a total order on I.

2.7

Let A be a finite commutative group, and $\chi:A\to E_\lambda^\times$ a nontrivial character. We have

$$\sum_{a\in A}\chi(a)=0. \tag{2.7.1}$$

We will prove the cohomological analogue of (2.7.1) by transposing the following proof: if $x \in A$, $a \mapsto xa$ is a permutation of A, and

$$\sum_{a\in A} \chi(a) = \sum_{a\in A} \chi(xa) = \chi(x) \sum_{a\in A} \chi(a) \qquad \text{, whence}$$
$$(\chi(x) - 1) \sum_{a\in A} = 0,$$

and by hypothesis there exists x such that $\chi(x) - 1 \neq 0$.

Theorem (2.7*)**.** *Let G_0 be a connected commutative algebraic group over $\mathbb{F}_q$ and $\chi : G_0(\mathbb{F}_q) \to E_\lambda^\times$ a nontrivial character. We have*

$$\mathrm{H}_c^\bullet(G, \mathscr{F}(\chi)) = 0. \tag{2.7.1*}$$

For x a rational point of G, let t_x be the translation $t_x(g) = xg$ of G. The formula $\mathfrak{L}t_x = t_{\mathfrak{L}(x)}\mathfrak{L}$ expresses that $(t_x, t_{\mathfrak{L}(x)})$ is an automorphism of the diagram $G \xrightarrow{\mathfrak{L}} G$ (G equipped with the torsor of Lang). Let $\rho(g)$ be the automorphism of $(G, \mathscr{F}(\chi))$ induced by it. For $g \in G_0(\mathbb{F}_q)$, i.e. for $\mathfrak{L}(g) = e$, it is the identity on G, and multiplication by $\chi(g)^{-1}$ on $\mathscr{F}(\chi)$.

Let $\rho_H(g)$ denote the automorphism of $\mathrm{H}_c^\bullet(G, \mathscr{F}(\chi))$ induced by $\rho(g)$. A homotopy argument (Lemma 2.8 below) shows that $\rho_H(g) = \rho_H(e)$, and hence is the identity. On the other hand, for $g \in G_0(\mathbb{F}_q)$, $\rho_H(g)$ is multiplication by $(\chi^{-1}(g) :$ on $\mathrm{H}^\bullet(G, \mathscr{F}(\chi))$, multiplication by $(\chi^{-1}(g) - 1)$ is zero. Taking g such that $\chi(g) \neq 1$, we obtain 2.7.

Lemma 2.8. *Let X and Y be two schemes over an algebraically closed field k, with X separated and of finite type and Y connected. Let $\mathscr{F}$ be a sheaf on X and let (ρ, ε) be a family of endomorphisms of $(X, \mathscr{F})$ parametrized by Y:*

$$\rho : Y \times_k X \to Y \times_k X \qquad \textit{is a } Y\textit{-morphism, and}$$
$$\varepsilon : \rho^* \mathrm{pr}_2^* \mathscr{F} \to \mathrm{pr}_2^* \mathscr{F} \qquad \textit{a morphism of sheaves.}$$

Assume that ρ is proper. For $y \in Y(k)$, let $\rho_H(y)^*$ denote the endomorphism of $\mathrm{H}_c^\bullet(X, \mathscr{F})$ induced by $\rho_y : X \to X$ and $\varepsilon_y : \rho_y^* \mathscr{F} \to \mathscr{F}$. Then, $\rho_H(y)^*$ is independent of y.

Indeed, $\mathsf{R}^p \mathrm{pr}_{1!} \mathrm{pr}_2^* \mathscr{F}$ is the constant sheaf on Y with fiber $\mathrm{H}^p(X, \mathscr{F})$, and $\rho_H(y)^*$ is the fiber at y of the endomorphism

$$\mathsf{R}^p \mathrm{pr}_{1!} \mathrm{pr}_2^* \mathscr{F} \xrightarrow{\rho^*} \mathsf{R}^p \mathrm{pr}_{1!} \rho^* \mathrm{pr}_2^* \mathscr{F} \xrightarrow{\varepsilon} \mathsf{R}^p \mathrm{pr}_{1!} \mathrm{pr}_2^* \mathscr{F}$$

of this sheaf.

2.9 Remark

Let G_0 be a connected algebraic group over $\mathbb{F}_q$ and $\rho : G_0(\mathbb{F}_q) \to \mathrm{GL}(V)$ a linear representation such that $V^{G_0(\mathbb{F}_q)} = 0$. Then again $\mathrm{H}_c^\bullet(G, \rho(L)) = 0$.

3 Sums in one variable

3.1

Weil was the first to apply "cohomological" methods to the study of trigonometric sums in one variable; since he had proved the analogue of the Riemann hypothesis for Artin's L functions over function fields,

these methods gave him excellent estimates (of order O(square root of the number of terms)) and an understanding of how these sums behave under "extension of the base field."

The substance of this section is a presentation, in cohomological language, of his results.

3.2

Cohomological methods here lead us to compute the groups $\mathrm{H}^i_c(X, \mathscr{F})$, where $\mathscr{F}_0$ is an E_λ-sheaf on a curve $X - 0$ over $\mathbb{F}_q$. These groups vanish for $i \neq 0, 1, 2$, and for $i = 0, 2$, they have a simple interpretation (1.8 a,b,c). Furthermore, the Euler-Poincaré characteristic $\chi_c(\mathscr{F}) = \sum(-1)^i \dim \mathrm{H}^i_c(X, \mathscr{F})$ (which is also equal to $\chi(\mathscr{F}) = \sum(-1)^i \dim \mathrm{H}^i(X, \mathscr{F})$) can be computed in terms of x, the rank of $\mathscr{F}$ at the generic points of X, and the ramification of $\mathscr{F}$. The essential result is the following.

Let $\bar{X}$ be a smooth connected projective curve of genus g over an algebraically closed field k, let X be the dense open subset of $\bar{X}$ complementary to a finite set S of points, and let $\mathscr{F}$ be a smooth E_λ-sheaf on X. Let $\chi(X) = 2 - 2g - \#S$ be the Euler–Poincaré characteristic of X, and let $\mathrm{rg}(\mathscr{F})$ be the rank of $\mathscr{F}$. For each point $s \in S$, we define an integer $\mathrm{Sw}_s(\mathscr{F})$, the Swan conductor, measuring the wild ramification of $\mathscr{F}$, and

$$\chi_c(\mathscr{F}) = \mathrm{rg}(\mathscr{F}) \cdot \chi(X) - \sum_{s \in S} \mathrm{Sw}_s(\mathscr{F}) \tag{3.2.1}$$

[29].

3.3

Let $\bar{X}$, $j : X \hookrightarrow \bar{X}$ and $\mathscr{F}$ as in 3.2. The Poincaré duality theorem takes the particularly convenient form: $\mathrm{H}^i(\bar{X}, j_*\mathscr{F})$ and $\mathrm{H}^{2-i}(\bar{X}, j_*(\mathscr{F}^\vee(1)))$ are dual to each other (Duality, 1.3).

3.4

Take $k = \mathbb{F}$, and suppose that X, $\bar{X}$, and $\mathscr{F}$ arise from X_0, $\bar{X}_0$, and $\mathscr{F}_0$ over $\mathbb{F}_q$. If $\mathscr{F}_0$ becomes trivial on a finite covering of X_0, Weil proved that the complex conjugates of the eigenvalues of F^* on $\mathrm{H}^i(\bar{X}, j_*\mathscr{F})$ have absolute value $q^{i/2}$. Such sheaves $\mathscr{F}_0$ correspond to Artin L-functions over the function field of $\bar{X}_0$.

3.5

Under the same hypotheses, or more generally if E_λ is the completion at a place λ of a number field E and if $\mathscr{F}_0$ belongs to an infinite compatible system of v-adic representations (v a place of E), we can compute

$$\prod_i \det(-F^*, \mathrm{H}^i(X, \mathscr{F}))^{(-1)^i}$$

from *local* information on $\mathscr{F}_0$. This is explained in [13]. For trivial $\mathscr{F}_0$ on a finite covering of X_0, it is the expression of the constant in the functional equation of an Artin L-function as a product of local constants.

3.5 Example

Let ψ be the character $\exp\left(\frac{2\pi i}{p} \mathrm{tr}_{\mathbb{F}_q/\mathbb{F}_p}\right)$ of $\mathbb{F}_q$; we have $\psi(a^p - a) = 0$. Let X_0 be a smooth projective geometrically irreducible curve of genus g over $\mathbb{F}_q$, and let f be a rational function on X_0, i.e. a morphism

$f : X_0 \to \mathbb{P}^1$, not identically equal to ∞. We are interested in the sum

$$S'_f = \sum_{\substack{x \in X_0(\mathbb{F}_q) \\ f(x) \neq \infty}} \psi(f(x)).$$

This sum is zero for f of the form $g^p - g$. This suggests modifying the sum S'_f as follows:

a) for any closed point x of X_0, set $v_x(f) =$ the order of the pole of f at x if $f(x) = \infty$, and $v_x(f) = 0$ otherwise; also set $v_x^*(f) = \inf v_x(f + g^p - g)$ (the infimum being over g).

b) If $v_x^*(f) = 0$, $x \in X_0(\mathbb{F}_q)$, and $f + g^p - g$ is regular at x, put $\psi(f(x)) = \psi((f + g^p - g)(x))$. Finally set

$$S_f = \sum_{x \in X_0(\mathbb{F}_q)}{}' \psi(f(x)), \tag{3.5.1}$$

where $(-)'$ indicates that the sum runs over those x for which $v_x^*(f) = 0$.

We have $S_f = S_{f+g^p-g}$. We shall verify that if f is not of the form $g^p - g + c^{te}$, then

$$|S_f| \leqslant \left(2g - 2 + \sum_{v_x^*(f) \neq 0} [k(x) : \mathbb{F}_q](1 + v_x^*(f)) \right) q^{1/2}. \tag{3.5.2}$$

We begin by passing from complex coefficients to ℓ-adic coefficients, replacing ψ by a character of the form $\psi_0 \circ \mathrm{tr}_{\mathbb{F}_q/\mathbb{F}_p}$, with $\psi_0 : \mathbb{F}_p \hookrightarrow E_\lambda^\times$. For $j : U_0 \hookrightarrow X_0$ the inclusion of the open where $f \neq \infty$, we then prove that

$$S_f = \sum (-1)^i \,\mathrm{tr}(F^*, \mathrm{H}^i(X, j_* \mathscr{F}(\psi f))). \tag{3.5.3}$$

The trace formula reduces this statement to the following (for $x \in X_0(\mathbb{F}_q)$):

a) If $v_x^*(f) = 0$, then F_x^* on $j_* \mathscr{F}(\psi f)$ is $\psi(f(x))$;

b) If $v_x^*(f) \neq 0$, then $j_* \mathscr{F}(\psi f)$ is ramified at x: $(j_* \mathscr{F}(\psi f))_{\bar{x}} = 0$.

Formula a) follows from (1.7.6) if $v_x(f) = 0$, and the general case reduces to this one by replacing f by $f + g^p - g$: up to isomorphism, this does not change $\mathscr{F}(\psi f)_0$ on the open where f and g are regular (1.3).

Formula b) follows from

$$\mathrm{Sw}_x \mathscr{F}(f, \psi) = v_x^*(f). \tag{3.5.4}$$

After reduction to the case $v_x(f) = v_x^*(f)$ (hence $p \nmid v_x(f)$) and extension of scalars to $\mathbb{F}$, this formula can be found in [34, 4.4].

Finally, we check that the sheaf $\mathscr{F}(\psi f)$ on U is nonconstant if f is not of the form $g^p - g + c^{te}$: since ψ_0 is injective, the triviality of $\mathscr{F}(\psi f) = \mathscr{F}(\psi_0 f)$ (1.8.ii) is equivalent to that of the $\mathbb{F}_q$-torsor defined by the equation; it would be the inverse image of a $\mathbb{F}_q$-torsor on $\mathrm{Spec}(\mathbb{F}_q)$, with equation $T^p - T - \lambda = 0$, and the $\mathbb{F}_p$-torsor equation $T^p - T - (f - \lambda) = 0$ on U_0 would be trivial and f would therefore be of the form $g^p - g + \lambda$. The $\mathrm{H}^i(\bar{X}, j_* \mathscr{F}(\psi f))$ therefore vanish for $i \neq 1$, and formula (3.5.3) reduces to

$$S_f = -\,\mathrm{tr}(F^*, \mathrm{H}^1(\bar{X}, j_* \mathscr{F}(\psi f))) \tag{3.5.5}$$

and, by (3.2.1) and (3.5.4), the dimension of H^1 is $2g - 2 + \sum_{v_x^*(f) > 0} [k(x) : \mathbb{F}_q](1 + v_x^*(f))$; moreover, $-S_f$ is the sum of this many eigenvalues of F^*, each having complex absolute value $q^{1/2}$.

3.6

Suppose that, for an automorphism σ of X_0, we have

$$f(\sigma x) = -f(x).$$

The sum S_f is then real. If σ is an involution, Poincaré duality allows us to say a little more: set $\mathscr{F}_0 = j_*\mathscr{F}(\psi f)$, $\mathscr{G}_0 = j_*\mathscr{F}(\psi(-f))$, we have

a) $\mathscr{F}_0$ and $\mathscr{G}_0$ are in duality,

b) $\sigma^*\mathscr{F}_0 \xrightarrow{\sim} \mathscr{G}_0$ and $\sigma^*\mathscr{G}_0 \xrightarrow{\sim} \mathscr{F}_0$, for natural isomorphisms such that the composite $\mathscr{F}_0 = (\sigma^2)^*\mathscr{F}_0 \xrightarrow{\sim} \sigma^*\mathscr{G}_0 \xrightarrow{\sim} \mathscr{F}_0$ is the identity.

c) the pairing $\mathscr{F}_0 \otimes \mathscr{G}_0 \to E_\lambda$ satisfies $\sigma^*(f \cdot g) = \sigma^*(f) \cdot \sigma^*(g)$.

Passing to cohomology, we find that $\mathrm{H}^1(X, \mathscr{F})$ and $\mathrm{H}^1(X, \mathscr{F})$ are in perfect duality with values in $E_\lambda(1)$, and that the bilinear form $\alpha \cdot \sigma^*\beta$ on $\mathrm{H}^1(X, \mathscr{F})$ is *alternating*: σ^* acts trivially on $E_\lambda(1)$, and

$$\alpha \cdot \sigma^*\beta = \sigma^*(\alpha \cdot \sigma^*\beta) = \sigma^*\alpha \cdot \beta = -\beta \cdot \sigma^*\alpha.$$

We conclude that $\mathrm{H}^1(X, \mathscr{F})$ is of even dimension (we also check easily that each nonzero $v_x^*(f)$ is odd) and that the eigenvalues of F^* on $\mathrm{H}^1(X, \mathscr{F})$ occur in pairs α and q/α.

3.7 Example

This applies to the Kloosterman sums $\sum_{x \in \mathbb{F}_q^\times} \psi\left(x + \frac{a}{x}\right)$ (take $X_0 = \mathbb{P}^1$, $f = x + \frac{a}{x}$, $\sigma x = -x$; the poles of f are 0 and ∞, and at each of them $v_x^*(f) = 1$; the dimension of H^1 is $-2 + 2 + 2 = 2$). We therefore have (for $a \neq 0$)

$$\sum_{\substack{xy=a \\ x,y \in \mathbb{F}_{q^n}}} \exp\left(\frac{2\pi i}{p} \operatorname{tr}_{\mathbb{F}_{q^n}/\mathbb{F}_p}(x+y)\right) = (-\alpha^n + \alpha^{-n}) \qquad , \alpha\bar{\alpha} = q.$$

This result is due to L. Carlitz [9].

We now give an application of a Lang–Weil method.

Proposition 3.8. *Let $P \in \mathbb{F}_q[X_1, \ldots, X_n]$ be a polynomial in n variables, of degree d, which is not of the form $Q^p - Q + C^{te}$. Again setting $\psi(x) = \exp\left(\frac{2\pi i}{p} \operatorname{tr}_{\mathbb{F}_q/\mathbb{F}_p}(x)\right)$, we have*

$$\left| \sum_{x_i \in \mathbb{F}_q} \psi P(x_1, \ldots, x_n) \right| \leqslant (d+1) q^{n - \frac{1}{2}}.$$

For the left-hand side we have the trivial estimate q^n. It is therefore enough to prove 3.8 when $d - 1 < q^{1/2}$; assume therefore that $d < q + 1$, and let P_d be the homogeneous part of degree d of P. Recall:

Lemma 3.9. *A hypersurface of degree d in $\mathbb{P}^r$ ($r \geqslant i$) cannot contain all rational points over $\mathbb{F}_q$ unless $d \geqslant q + 1$.*

We argue by induction: if there exists a rational hyperplane not entirely contained in the hypersurface (this is not the case for $r = 1$), we apply the induction hypothesis to the intersection of the hypersurface with this hyperplane. Otherwise, the degree d is $\geqslant$ the number of rational hyperplanes, $\geqslant q + 1$.

Let us now distinguish two cases.

Case 1: $p \nmid d$**.** Applying the lemma to P_d, we see that, after making a linear change of variables if necessary, we may assume that $P_d(1,0,\dots,0) \neq 0$, i.e. that the coefficient of X_1^d in P is nonzero. A polynomial in 1 variable

$$S(X) = \sum_{i=0}^{d} a_i x^i,$$

with $a_d \neq 0$ ($p \nmid d$) is never of the form $Q^p - Q + C^{te}$, and the (3.5.2) estimate is reduced to

$$\left|\sum \psi(S(x))\right| \leqslant (d-1)q^{1/2}.$$

Applying this estimate to the partial sums obtained by varying only x_1, we find

$$\left|\sum \psi P(x_1,\dots,x_n)\right| = \left|\sum_{x_2,\dots,x_n}\sum_{x_1} \psi P(x_1,\dots,x_n)\right| \leqslant q^{n-1}(d-1)q^{1/2}$$

as promised.

Case 2: $p \mid d$ **($d > 0$).** If P_d is a p-th power, replacing P by $P - (P_d - P_d^{1/p})$ does not change the sum under consideration and lowers the degree: this case is disposed of by induction on d. Otherwise, the differential of P_d is not identically zero; applying 3.9, one can assume, after a linear change of variables if necessary, that it is nonzero at the point $(1,0,\dots,0)$. If we write

$$P_d = \sum_{i=0}^{d} X_1^{d-i} S_i(X_2,\dots,X_n),$$

this means that the linear form S_1 is not identically zero.

The form S_0 is constant, and by replacing P with $P - (S_0 X_1^d - S_0^{1/p} X_1^{d/p})$, we can assume that it is zero. Finally, denote by $-\lambda$ the coefficient of X_1^{d-1} in P. For fixed $x_2,\dots,x_n$, we have

$$P(X_1,x_2,\dots,x_n) = (S_1(x_2,\dots,x_n) - \lambda)X_1^{d-1} + \text{terms of lower degree in } X_1$$

and if $S_1(x_2,\dots,x_n) \neq \lambda$, we therefore have

$$\left|\sum_{x_1} \psi P(x_1,\dots,x_n)\right| \leqslant (d-2)q^{1/2}.$$

In total,

$$\begin{aligned}\left|\sum \psi P(x_1,\dots,x_n)\right| &\leqslant \left|\sum_{S=\lambda} \psi P(x_1,\dots,x_n)\right| + \sum_{S(X_2,\dots,X_n)\neq\lambda} \left|\sum_{x_1} \psi P(x_1,\dots,x_n)\right| \\ &\leqslant q^{n-1} + (q^{n-1} - q^{n-2})(d-2)q^{1/2} \\ &< (d-2)q^{n-1/2} + q^{n-1} \\ &< (d-1)q^{n-1/2}.\end{aligned}$$

Another result of this nature is given by R.A. Smith [37].

4 Gauss and Jacobi sums

4.1

Let k be a finite field of characteristic p, let χ be a character of $k^\times$, and let ψ be a nontrivial character of the additive group of k. We take the following as the definition of Gauss sums:

$$\tau(\chi,\psi) = -\sum_{x\in k^\times} \psi(x)\chi^{-1}(x) \tag{4.1.1}$$

(note the sign). Classically, χ and ψ are complex-valued. We take them to have values in $E_\lambda^\times$ (see the proof of 1.15). Regard $-\tau(\chi,\psi)$ as a sum over the rational points of the scheme $\mathbb{G}_m$ over k. By Section 1, we have $-\tau(\chi,\psi) = \mathrm{tr}(F^*, \mathrm{H}_c^*(\mathbb{G}_m, \mathscr{F}(\psi\chi^{-1}))$. Moreover,

Proposition 4.2. *The cohomology of $\mathbb{G}_m$ with coefficients in $\mathscr{F}(\psi\chi^{-1})$ satisfies*

(i) $\mathrm{H}_c^i = 0$ *for* $i \neq 1$, *and* $\dim \mathrm{H}_c^1 = 1$.

(ii) F^*, *acting on* H_c^1, *is multiplication by* $\tau(\chi,\psi)$.

(iii) If χ *is nontrivial, we have* $\mathrm{H}_c^\bullet \xrightarrow{\sim} \mathrm{H}^\bullet$.

Proof. For any n prime to p, denote by K_n the $\boldsymbol{\mu}_n$-torsor on $\mathbb{G}_m$ defined by the exact Kümmer sequence $0 \to \boldsymbol{\mu}_n \to \mathbb{G}_m \xrightarrow{x^n} \mathbb{G}_m \to 0$. If k has q elements, then over k one has $\boldsymbol{\mu}_{q-1} = k^\times$, and the Lang torsor on $\mathbb{G}_m/k$ is K_{q-1}. Hence $\mathscr{F}(\chi^{-1}) = \chi(K_{q-1})$. Assertion 4.2(ii) follows from (i,iii), which in turn follow from the following geometric statement, where $\mathscr{F}(\psi)$ denotes the sheaf on $\mathbb{G}_m/\mathbb{F}$ obtained by extending scalars from k to $\mathbb{F}$ in $\mathscr{F}(\psi)$ on $\mathbb{G}_m/k$ (1.8.b). □

Proposition 4.3. *Let* $\chi : \boldsymbol{\mu}_n \to E_\lambda^\times$. *The cohomology of* $\mathbb{G}_m$ *with coefficients in* $\mathscr{F}(\psi)\otimes\chi(K_n)$ *satisfies*

(i) $\mathrm{H}_c^i = 0$ *for* $i \neq 1$, *and* $\dim \mathrm{H}_c^1 = 1$.

(ii) If χ *is nontrivial, we have* $\mathrm{H}_c^\bullet \xrightarrow{\sim} \mathrm{H}^\bullet$.

Proof. The sheaf $\mathscr{F}(\psi)$ is the restriction to $\mathbb{G}_m$ of a sheaf locally constant on $\mathbb{G}_a$, wildly ramified at infinity, with Swan conductor 1. The sheaf $\chi(K_n)$ is constant if $\chi = 1$; if $\chi \neq 1$, it is tamely ramified at 0 and ∞.

The sheaf $\mathscr{F}(\psi)\otimes\chi(K_n)$ is therefore ramified at ∞; applying 1.18(b,c), we find that $\mathrm{H}_c^i(\mathbb{G}_m, \mathscr{F}(\psi)\otimes\chi(K_n)) = 0$ for $i \neq 1$. If $\chi \neq 1$, it is ramified at 0 and ∞, and (ii) follows from 1.19.a.

The Swan conductors are 0 at 0 and 1 at ∞. By (3.2.1), the Euler–Poincaré characteristic is therefore -1, which completes the proof. □

4.4 Remark

If χ is nontrivial, 4.2(iii) and Poincaré duality show that $\mathrm{H}_c^1(\mathbb{G}_m, \mathscr{F}(\psi\chi^{-1}))$ and $\mathrm{H}_c^1(\mathbb{G}_m, \mathscr{F}(\psi^{-1}\chi))$ are in duality (duality with values in $E_\lambda(-1)$). We therefore have $\tau(\chi,\psi)\cdot\tau(\chi^{-1},\psi^{-1}) = q$, i.e. $|\tau(\chi,\psi)| = 1$.

4.5

If k is an extension of degree N of $\mathbb{F}_q$, we can also regard (4.1.1) as a sum in N variables over $\mathbb{F}_q$. More generally, let k be an étale algebra over $\mathbb{F}_q$, of degree N over $\mathbb{F}_q$. It is a product of fields k_i of degrees N_i, and we set

$$\varepsilon(k) = (-1)^{\sum(N_i+1)}. \tag{4.5.1}$$

This is the sign of the permutation of $S = \hom_{\mathbb{F}_q}(k, \mathbb{F})$ induced by the Frobenius substitution $\varphi \in \mathrm{Gal}(\mathbb{F}/\mathbb{F}_q)$.

Let $\psi : \mathbb{F}_q \to E_\lambda^\times$ be a nontrivial character, and let $\chi : k^\times \to E_\lambda^\times$. We set

$$\tau_{\mathbb{F}_q}(\chi, \psi) = (-1)^N \sum_{x \in k^\times} \psi \operatorname{tr}_{k/\mathbb{F}_q}(x) \cdot \chi^{-1}(x). \tag{4.5.2}$$

If χ has coordinates $\chi_i : k_i^\times \to E_\lambda^\times$, we have the elementary identity

$$\tau_{\mathbb{F}_q}(\chi, \psi) = \varepsilon(k) \prod \tau(\chi_i, \psi \circ \operatorname{tr}_{k_i/\mathbb{F}_q}). \tag{4.5.3}$$

After some preliminaries, we give in 4.10 a cohomological interpretation of the sums (4.5.2). In 4.12, we will interpret the Hasse–Davenport identity as a twisted form (cf. 1.12) of the following special case of (4.5.3): for $k = \mathbb{F}_q^N$, and χ a character of $\mathbb{F}_q^\times$, we have $\tau_{\mathbb{F}_q}(\chi \circ N_{k/\mathbb{F}_q}, \psi) = \tau(\chi, \psi)^N$.

4.6

Recall that for M a finitely generated projective module over a ring A, the functor $\mathrm{Spec}(B) \mapsto M \otimes_A B$ from affine schemes over $\mathrm{Spec}(A)$ to Ens is represented by the affine scheme $\mathbb{V}(M^\vee)$ (EGA notation), the spectrum of $\mathrm{Sym}_A^\bullet(M^\vee)$. If $M = A^n$, this is the standard affine space of dimension n.

Suppose that M is a unital A-algebra, and let $V = \mathbb{V}(M^\vee)$. By definition, for any B equipped with an A-algebra structure, the set $V(B)$ of points of V with coordinates in B is $M \otimes_A B$. Since the functor $B \mapsto M \otimes_A B$ takes values in unital rings, V is a unital ring scheme over $\mathrm{Spec}(A)$. The norm and trace morphisms $M \otimes_A B \to B$ are functorial in B; they therefore correspond to morphisms of schemes N and T from V to $\mathbb{G}_a$. We shall consider the following schemes obtained from V:

a) V^* is the open subscheme of invertible elements of V (a group scheme under $\cdot$);

b) W is the hyperplane of equation $T = 0$ and $W^* = W \cap V^*$;

c) P is the hyperplane at infinity $V \smallsetminus \{0\}/\mathbb{G}_m$ of the affine space V over $\mathrm{Spec}(A)$. If Q is the hyperplane at infinity of W, $W^*/\mathbb{G}_m$ and $V^*/\mathbb{G}_m$ are open subsets of the projective spaces Q and P over $\mathrm{Spec}(A)$.

$$\begin{array}{ccc} W^* & \hookrightarrow & V^* \\ \downarrow{\scriptstyle\pi} & & \downarrow{\scriptstyle\pi} \\ W^*/\mathbb{G}_m & \hookrightarrow & V^*/\mathbb{G}_m \end{array} \qquad \subset \qquad \begin{array}{ccc} W \smallsetminus \{0\} & \hookrightarrow & V \smallsetminus \{0\} \\ \downarrow{\scriptstyle\pi} & & \downarrow{\scriptstyle\pi} \\ Q & \hookrightarrow & P. \end{array} \tag{4.6.1}$$

If $M = A^I$, I a finite set, then $V \simeq \mathbb{G}_a^I$, $V^* = \mathbb{G}_m^I$, $V^*/\mathbb{G}_m$ is the torus $\mathbb{G}_m^I/(\mathbb{G}_m \text{ diagonal})$, N and T are given by $\prod x_i$ and $\sum x_i$, and Q is therefore the projective hyperplane with equation $\sum x_i = 0$ in P.

The case of interest is that in which M is finite étale over A. The previous description then applies locally to $\mathrm{Spec}(A)$ (for the étale topology) and we can write $V^* = \mathbb{G}_m^I$, for I a locally constant sheaf of finite sets on $\mathrm{Spec}(A)$. If, for example, A is a field with algebraic closure $\bar{A}$, and M is a separable A-algebra, we put $I = \hom_A(M, \bar{A})$, and over $\bar{A}$ we have $V \sim \mathbb{G}_a^I$. Via this isomorphism, N and T are given by $\prod x_i$ and $\sum x_i$.

4.7 The Kummer torsor

Let S be a scheme, let n be an integer invertible on S, and let G be a commutative group scheme with connected fibers (written multiplicatively) over S. The sequence

$$0 \longrightarrow G_n \longrightarrow G \xrightarrow{x^n} G \longrightarrow 0$$

is exact. It defines a G_n-torsor $K_n(G)$ (or simply K_n) on G. For $\chi : G_n \to E_\lambda^\times$ a homomorphism from the étale S-sheaf G_n to the constant sheaf $E_\lambda^\times$, we denote by $\mathscr{K}_n(\chi)$ the E_λ-sheaf $\chi^{-1}(K_n)$.

The K_n torsors form an inverse system of torsors under the projective system of groups G_n (transition morphisms $x \mapsto x^d : G_{nd} \to G_n$). This expresses the commutativity of the diagrams

$$\begin{array}{ccccccccc} 0 & \longrightarrow & G_{nd} & \longrightarrow & G & \xrightarrow{x^{nd}} & G & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle x^d} & & \downarrow{\scriptstyle x^d} & & \| & & \\ 0 & \longrightarrow & G_n & \longrightarrow & G & \xrightarrow{x^n} & G & \longrightarrow & 0. \end{array}$$

We therefore have $\mathscr{K}_n(\chi) = \mathscr{K}_{nd}(\chi \circ x^d)$.

4.8

Apply the construction of 4.6 with $A = \mathbb{F}_q$ and with $M = k$ an étale algebra over $\mathbb{F}_q$. In accordance with our general conventions, we denote by a subscript 0 the $\mathbb{F}_q$-schemes denoted $V, V^*, \ldots$ in 4.6. The same letters without a subscript denote the schemes over $\mathbb{F}$ obtained by extension of scalars.

We put $I = \hom(k, \mathbb{F})$; then $V \sim \mathbb{G}_a^I$ and T is given by $(x_i) \mapsto \sum x_i$.

$$\mathscr{F}(\psi \circ \mathrm{tr}_{k/\mathbb{F}_q}) = T^* \mathscr{F}(\psi) = \bigotimes_i \mathrm{pr}_i^* \mathscr{F}(\psi). \tag{4.8.1}$$

Since $V^* \sim \mathbb{G} + m^I$, a character χ of $V_n^* \sim \boldsymbol{\mu}_n^I$, with values in $E_\lambda^\times$, amounts to a family $(\chi_i)_{i \in I}$ of characters of $\boldsymbol{\mu}_n$ indexed by I. It is defined over $\mathbb{F}_q$ if, for all $\sigma \in \mathrm{Gal}(\mathbb{F}/\mathbb{F}_q)$, we have $\chi_{\sigma_i} = \chi_i \circ \sigma^{-1}$. It then defines a E_λ-sheaf $\mathscr{K}_n((\chi_i)_{i \in I})$ on V_0^*. If the product of the χ_i is trivial, χ factors through a character of $(V_0^*/\mathbb{G}_m)_n$ and $\mathscr{K}_n((\chi_i)_{i \in I})$ is the inverse image of a sheaf, denoted in the same way, on $V - 0^*/\mathbb{G}_m$. This construction is related to the Lang torsor as follows.

Lemma 4.9. *(i) For n sufficiently divisible, we have a commutative diagram*

$$\begin{array}{ccccccccc} 0 & \longrightarrow & (V_0^*)_n & \longrightarrow & V_0^* & \xrightarrow{x^n} & V_0^* & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle \tau} & & \downarrow{\scriptstyle \tau} & & \| & & \\ 0 & \longrightarrow & k^\times & \longrightarrow & V_0^* & \xrightarrow{\mathfrak{L}} & V_0^* & \longrightarrow & 0; \end{array}$$

if χ is a character $\chi : k^\times \to E_\lambda^\times$, we have $\mathscr{F}(\chi) = \mathscr{K}_n(\chi \circ \tau)$.

(ii) For sufficiently divisible n, τ identifies $k^\times$ with the coinvariants of $\mathrm{Gal}(\bar{\mathbb{F}}/F)$ acting on $V_n^* \sim \boldsymbol{\mu}_n^I$.

(iii) For k a field, $N = [k : \mathbb{F}_q]$, $\omega \in I$ an embedding of k in $\mathbb{F}$, and $n = q^N - 1$, the index component ω of $\chi \circ \tau$ is $\chi \circ \omega^{-1}$.

(iv) If χ is nontrivial on each factor of k, the $(\chi \circ \tau)_i$ are all nontrivial.

It is enough to prove the lemma when k is a field of degree N over $\mathbb{F}_q$. In this case, n is "sufficiently divisible" if $q^N - 1 \mid n$. Choose an embedding ω of k into $\mathbb{F}_q$; then I is identified with $\mathbb{Z}/N$: the element $i \in \mathbb{Z}/N$ corresponds to $\omega_i = \omega^{q^i}$. Via the isomorphism $V_0^*(\mathbb{F}) = F^{\times I}$, we have

a) $x \in k^\times$ corresponds to $(\omega_i(x)) \in \mathbb{F}^{\times I}$;

b) $F((x_i)_{i\in\mathbb{Z}/N}) = (x_{i-1}^q)_{i\in\mathbb{Z}/N}$.

A character $\chi = (\chi_i)$ of $V_n^* \sim \boldsymbol{\mu}_n^I$ is defined over $\mathbb{F}_q$ if $\chi_{-i} = \chi_0(x^{q^i})$ $(i \in \mathbb{Z})$. If $q^N - 1 \mid n$, there are $q^N - 1$ such characters: χ_0 factors through $\boldsymbol{\mu}_{q^N-1}$ and determines the χ_i. To prove (ii), it is therefore sufficient to verify (i) and (iii) (or its corollary (iv)) which ensures that $\chi \mapsto \chi \circ \tau$ is injective.

Let us prove (i) and (iii) for $n = q^N - 1$. Write the group of endomorphisms of $V^* \sim \mathbb{G}_m^I$ additively; in particular, denote by n the $x \mapsto x^n$ operator. If α is the cyclic permutation operator $(x_i) \mapsto (x_{i-1})$, we have $q^N - 1 = (q\alpha)^N - 1 = (q\alpha - 1)((q\alpha)^{N-1} + \cdots + 1)$. This determines τ: we have $\tau((x_i)) = \prod_{0\leqslant j<N} x_{i-j}^{q^j}$, and the induced map from $(V_0^*)_n$ to $k^\times$ is [as in a) above] $(x_i) \mapsto \prod x_{-i}^{q^i}$; hence (iii) follows.

Proposition 4.10. *The cohomology of V^* with coefficients in $\mathscr{F}(\chi^{-1} \cdot \psi \operatorname{tr}_{k/\mathbb{F}_q})$ satisfies*

(i) $\mathrm{H}_c^i = 0$ *for* $i \neq N$, *and* $\dim \mathrm{H}_c^N = 1$.

(ii) On H_c^N, F^* *is multiplication by* $\tau_{\mathbb{F}_q}(\chi, \psi)$.

(iii) If χ *is nontrivial on each factor of* k, *we have* $\mathrm{H}_c^\bullet \xrightarrow{\sim} \mathrm{H}^\bullet$.

Applying 4.9(i), over $\mathbb{F}$, if $\chi \circ \tau = (\chi_i)_{i\in I}$, we have $\mathscr{F}(\chi) = \mathscr{K}_n((\chi_i)_{i\in I})$. Points (i) and (iii) therefore follow from the following more geometric statement (for (iii), apply 4.9(iv)), and (ii) follows from the trace formula:

Proposition 4.11. *Let $(\chi_i)_{i\in I}$ be a family of characters of $\boldsymbol{\mu}_n(\mathbb{F})$. The cohomology of $V^* \simeq \mathbb{G}_m^I$ with coefficients in $\mathscr{K}_n((\chi_i)_{i\in I}) \otimes \mathscr{F}(\psi \operatorname{tr}_{k/\mathbb{F}_q})$ satisfies*

(i) $\mathrm{H}_c^i = 0$ *for* $i \neq N$, *and* $\dim \mathrm{H}_c^N = 1$.

(ii) If the χ_i are all nontrivial, we have $\mathrm{H}_c^\bullet \xrightarrow{\sim} \mathrm{H}^\bullet$.

We have $V^* \sim \mathbb{G}_m^I$, $\mathscr{K}((\chi_i)) = \bigotimes_i \mathrm{pr}_i^* \chi_i(K_n(\mathbb{G}_m))$ and $\mathscr{F}(\psi \circ \operatorname{tr}_{\mathbb{F}_q/k}) = T^*\mathscr{F}(\psi) = \bigotimes_i \mathrm{pr}_i^* \mathscr{F}(\psi)$. The Künneth formula then applies, and 4.11 follows from 4.3.

4.12

From 2.4* and (Cycle, 1.3 Example 2), it also follows that the group of permutations σ of I such that $\chi_i = \chi_{\sigma i}$ $(i \in I)$ acts on H_c^N by multiplication by the sign $\varepsilon(\sigma)$. We deduce a second proof of the identity of Hasse-Davenport.

If χ is a character of $\mathbb{F}_q^\times$, the fact that, over $\mathbb{F}$, N is given by $(x_i) \mapsto \prod x_i$ gives $\mathscr{F}(\chi \circ N) = N^*\mathscr{F}(\chi) = \bigotimes_i \mathrm{pr}_i^* \mathscr{F}(\psi)$ and the Künneth formula gives

$$\mathrm{H}_c^\bullet(V^*, \mathscr{F}(\chi^{-1} \circ N, \psi \circ \mathrm{tr})) \sim \mathrm{H}_c^\bullet(\mathbb{G}_m, \mathscr{F}(\chi^{-1}\psi))^{\otimes I},$$

where the tensor product on the right-hand side is taken in the sense of 2.4*. Since $\mathrm{H}_c^1(\mathbb{G}_m, \mathscr{F}(\psi\chi^{-1}))$ is of dimension 1, its tensor power $\otimes I$, in the ordinary sense, depends only on the cardinality n of I. Applying (Cycle, 1.3 Example 2), we obtain a canonical isomorphism

$$\mathrm{H}_c^N\left(V, \mathscr{F}(\chi^{-1} \circ N) \otimes T^*\mathscr{F}(\psi)\right) \sim \mathrm{H}_c^1(\mathbb{G}_m, \mathscr{F}(\psi\chi^{-1})) \otimes_{\mathbb{Z}} \bigwedge^N \mathbb{Z}^I. \tag{4.12.1}$$

To compute the action of F^*, it is most convenient to adopt the Galois point of view and observe that, since the isomorphism (4.12.1) is canonical, it is compatible with the transport-of-structure action of $\mathrm{Gal}(\mathbb{F}/\mathbb{F}_q)$. If $\varepsilon(k)$ is the sign of the permutation φ of I, we find that

$$\begin{aligned}\tau_{\mathbb{F}_q}(\chi\circ N_{k/\mathbb{F}_q},\psi) &= \mathrm{tr}\left(\varphi^{-1}, \mathrm{H}_c^N\left(V^*, N^*\mathscr{F}(\chi^{-1})\otimes T^*\mathscr{F}(\psi)\right)\right)\\ &= \varepsilon(k)\,\mathrm{tr}\left(\varphi^{-1}, \mathrm{H}_c^1(\mathbb{G}_m, \mathscr{F}(\chi^{-1}\psi))\right)^N\\ &= \varepsilon(k)\tau(\chi,\psi)^N,\end{aligned}$$

that is,

$$\tau_{\mathbb{F}_q}\left(\chi\circ N_{k/\mathbb{F}_q},\psi\right) = \varepsilon(k)\tau(\chi,\psi)^N. \tag{4.12.2}$$

If k is a field, φ is a cyclic permutation of I, $\varepsilon(k) = (-1)^{N+1}$, and we obtain the Hasse–Davenport identity:

$$\tau\left(\chi\circ N_{k/\mathbb{F}_q}, \psi\circ \mathrm{tr}_{k/\mathbb{F}_q}\right) = (-1)^{N+1}\tau_{\mathbb{F}_q}\left(\chi\circ N_{k/\mathbb{F}_q},\psi\right) = \tau(\chi,\psi)^N.$$

Lemma 4.13. *For $\chi\circ\tau = (\chi_i)_{i\in I}$ as in 4.9(i), the following conditions are equivalent*

(i) $\chi|\mathbb{F}_q^\times$ is trivial.

(ii) The product of χ_i is trivial.

(iii) $\mathscr{F}(\chi) = \mathscr{K}_n((\chi_i))$ is the inverse image of a unique sheaf on $V^*/\mathbb{G}_m$.

(iv) The inverse image of $\mathscr{F}(\chi)$ on $\mathbb{G}_m$ (embedded in V^* by the structural morphism $\mathbb{F}_q\to k$) is trivial.

(i)⇒(ii). We regard χ as a character of $V^*/\mathbb{G}_m(\mathbb{F}_q) = k^\times/\mathbb{F}_q^\times$, and we take $\mathscr{F}(\chi)$ on $V^*/\mathbb{G}_m$.
(ii)⇒(iii). Likewise, we regard (χ_i) as a character of $(V^*/\mathbb{G}_m)_n$. The uniqueness in (iii) follows from the fact that V^* is a fibration with connected fibers over $V^*/\mathbb{G}_m$, and (iii)⇒(iv) is trivial.
(iv)⇒(i), (ii). This inverse image is $\mathscr{F}(\chi|\mathbb{F}_q^\times)$ and $\mathscr{K}_n(\prod\chi_i)$.

4.14

Let k be an étale algebra over $\mathbb{F}_q$, of dimension $N+1$, and let χ be a nontrivial character of $k^\times$, trivial on $\mathbb{F}_q^\times$. The Jacobi sum $J(\chi)$ is defined by

$$J(\chi) = (-1)^{N-1}\sum_{\substack{x\in k^\times/\mathbb{F}_q^\times\\ \mathrm{tr}(x)=0}}\chi^{-1}(x). \tag{4.14.1}$$

We have the following identity between Gauss sums and Jacobi sums.

Proposition 4.15. *For χ as above and ψ a nontrivial additive character of $\mathbb{F}_q$, we have*

$$qJ(\chi) = \tau_{\mathbb{F}_q}(\chi,\psi).$$

In the special case $k=\mathbb{F}_q^n$, formula (4.5.3) rewrites this as

$$qJ(\chi) = \prod_i \tau(\chi_i,\psi), \tag{4.15.1}$$

or equivalently as

$$\chi_0(-1)J(\chi) = (-1)^{N-1} \sum_{\substack{x_1,\dots,x_N \in \mathbb{F}_q^\times \\ \sum x_i = 1}} \prod_{i=1}^{N} \chi_i^{-1}(x_i) = \tau(\chi_0^{-1},\psi)^{-1} \prod_{i=1}^{N} \tau(\chi_i,\psi)$$

$$\chi_0^{-1} = \prod_{i=1}^{N} \chi_i$$

Proof of 4.15.

$$\tau_{\mathbb{F}_q}(\chi,\psi) = (-1)^{N+1} \sum_{x\in k^\times} \chi(x)^{-1}\psi\,\mathrm{tr}(x) = (-1)^{N+1} \sum_{x\in k^\times/\mathbb{F}_q^\times} \chi(x)^{-1} \sum_{\lambda\in\mathbb{F}_q^\times} \psi(\lambda\,\mathrm{tr}\,x).$$

The sum $\sum_{\lambda\in\mathbb{F}_q^\times} \psi(\lambda\,\mathrm{tr}\,x)$ equals $q-1$ if $\mathrm{tr}(x)=0$, and -1 if $\mathrm{tr}(x)\neq 0$. Therefore,

$$\tau_{\mathbb{F}_q}(\chi,\psi) = (-1)^{N+1} \left(q \sum_{x\in k^\times/\mathbb{F}_q^\times} \chi(x)^{-1} - \sum_{x\in k^\times/\mathbb{F}_q^\times} \chi(x)^{-1} \right).$$

The second term on the right-hand side is zero, since it is the sum of the values of a character, and 4.15 follows. □

Proposition 4.15 therefore has the following cohomological counterpart:

Proposition 4.16. *The cohomology of $W^*/\mathbb{G}_m$ (4.6, 4.8) with coefficients in $\mathscr{F}(\chi^{-1})$ satisfies*

(i) $\mathrm{H}_c^i = 0$ *for* $i \neq N-1$, *and* $\dim \mathrm{H}_c^{N-1} = 1$.

(ii) On H_c^{N-1}, F^* *is multiplication by* $J(\chi)$.

(iii) H_c^{N-1} *is canonically isomorphic to* $\mathrm{H}_c^{N+1}\left(V^*, \mathscr{F}(\chi^{-1}, \psi\circ \mathrm{tr}_{k/\mathbb{F}_q})\right)(1)$.

Assertion (ii) follows from (i) and the trace formula; (i) and (iii) follow from 4.11 and the following more geometric statement.

Proposition 4.17. *Let $(\chi_i)_{i\in I}$ be a family of nontrivial characters of $\boldsymbol{\mu}_n(\mathbb{F})$ whose product is 1. Then* $\mathrm{H}_c^{i-1}\left(W^*/\mathbb{G}_m, \mathscr{K}_m((\chi_i)_{i\in I})\right)$ *is canonically isomorphic to* $\mathrm{H}_c^{i+1}\left(V^*, \mathscr{K}_m((\chi_i)_{i\in I}) \otimes \mathscr{F}(\psi\,\mathrm{tr}_{k/\mathbb{F}_q})\right)(1)$.

The first line of 4.15, namely the projection formula, gives (π as in (4.6.1)).

$$\mathsf{R}^i\pi_!\left(\mathscr{K}_n((\chi_i)_{i\in I}) \otimes \mathscr{F}(\psi\,\mathrm{tr}_{k/\mathbb{F}_q})\right) = \mathscr{K}_n((\chi_i)_{i\in I}) \otimes \mathsf{R}^i\pi_!\mathscr{F}(\psi\,\mathrm{tr}_{k/\mathbb{F}_q}) \tag{4.17.1}$$

(on $V^*/\mathbb{G}_m$). Let us compute the sheaves $\mathsf{R}^i\pi_!\mathscr{F}(\psi\,\mathrm{tr}_{k/\mathbb{F}_q}) = \mathsf{R}^i\pi_!T^*\mathscr{F}(\psi)$. Let $v_0 : \widetilde{V}_0 \to V_0$ be the blow-up of V_0 at $\{0\}$. In the diagram

$$\begin{array}{ccccc} V_0 \smallsetminus \{0\} & \hookrightarrow & \widetilde{V}_0 & \xrightarrow{v_0} & V_0 \\ & \searrow^{\pi} & \downarrow{\scriptstyle \bar{\pi}} & & \\ & & P_0 & & \end{array} \tag{4.17.2}$$

π is a fibration whose fibers are punctured affine lines, $\widetilde{V}_0$ is the corresponding line bundle, and $Z_0 = v_0^{-1}(0)$ is its section 0. The $T^*\mathscr{F}(\psi)$ sheaf on $V - 0 \smallsetminus \{0\}$ extends to $(Tv_0)^*\mathscr{F}(\psi)$ on $\widetilde{V}_0$, and the restriction of this sheaf to Z_0 is the constant sheaf E_λ, because $T_0 v_0$ vanishes on Z_0. The long exact sequence for cohomology with compact supports is therefore

$$\longrightarrow \mathsf{R}^i\pi_!T^*\mathscr{F}(\psi) \longrightarrow \mathsf{R}^i\bar{\pi}_!(Tv)^*\mathscr{F}(\psi) \longrightarrow (E_\lambda \text{ for } i = 0,\ 0 \text{ otherwise}) \longrightarrow \tag{4.17.3}$$

The inverse image $\bar{\pi}^{-1}(Q_0)$ is the blow-up $\widetilde{W_0}$ of W_0 at 0; T_0V_0 vanishes on $\widetilde{W_0}$; hence $(Tv)^*\mathscr{F}(\psi) = E_\lambda$ on $\pi^{-1}(Q_0)$ and, since $\bar{\pi}$ is an affine-line fibration,

$$\mathsf{R}^i\bar{\pi}_!(Tv)^*\mathscr{F}(\psi)|Q = \begin{cases} 0 & \text{for } i \neq 2 \\ E_\lambda(-1) & \text{for } i = 2. \end{cases} \tag{4.17.4}$$

If $x \in P$, $x \notin Q$, the line $D = \pi^{-1}(x)$ is mapped isomorphically onto $\mathbb{G}_a$ by Tv; therefore (by 2.7*)

$$\mathrm{H}_c^\bullet(D, (Tv)^*\mathscr{F}(\psi)) = \mathrm{H}^\bullet(\mathbb{G}_a, \mathscr{F}(\psi)) = 0 \qquad \text{and}$$

$$\mathsf{R}^i\bar{\pi}_!(Tv)^*\mathscr{F}(\psi) = \begin{cases} 0 & \text{for } i \neq 2 \\ E_\lambda(-1)_Q & \text{for } i = 2 \end{cases} \tag{4.17.5}$$

Combining (4.17.3) and (4.17.5), we finally find

$$\mathsf{R}^i\pi_!T^*\mathscr{F}(\psi) = \begin{cases} 0 & \text{for } i \neq 1, 2 \\ E_\lambda & \text{for } i = 1 \\ E_\lambda(-1)_Q & \text{for } i = 2. \end{cases} \tag{4.17.6}$$

4.18

Let us compute the compactly supported cohomology of the sheaf $\mathscr{K}_n((\chi_i)) \otimes T^*\mathscr{F}(\psi)$ on V^* using the Leray spectral sequence of $\pi : V^* \to V^*/\mathbb{G}_m$. Applying (4.17.1) and (4.17.6), we obtain as initial terms $E_2^{p,1} = \mathrm{H}_c^p(V^*/\mathbb{G}_m, \mathscr{K}_n(\chi_i)) = 0$ (because $(\chi_i) \neq 0$) and $E_2^{p,2} = \mathrm{H}_c^p(W^*/\mathbb{G}_m, \mathscr{K}(\chi_i))(-1)$.

The spectral sequence reduces to an isomorphism, and 4.17 follows.

4.19

The sheaves $\mathscr{K}_n((\chi_i)_{i\in I})$ make sense over any field, or even over any base scheme. This allows us to generalize 4.16(i). With the notation of 4.6, suppose that M is finite étale of constant rank N over A, and let n be invertible in A. Let a be the projection of $W^*/\mathbb{G}_m$ to $\mathrm{Spec}(A)$. Let also χ be a character (morphism of sheaves) $\chi : (V^*/\mathbb{G}_m)_n \to E_\lambda^\times$, and $\mathscr{K}_n(\chi)$ the sheaf corresponding. Locally for the étale topology, we can regard χ as a family of characters $(\chi_i)_{i\in I}$ of $\boldsymbol{\mu}_n$, whose product is trivial.

Proposition 4.20. *(i) If χ is everywhere nontrivial, we have $\mathsf{R}^i a_!(\mathscr{K}_n(\chi)) = 0$ for $i \neq N-1$, and $\mathsf{R}^{N-1}a_!(\mathscr{K}_n(\chi))$ is smooth of rank 1.*

(ii) An automorphism σ of M which preserves χ acts on this $\mathsf{R}^{N-1}a_!$ by multiplication by the sign $\varepsilon(\sigma)$ of σ, seen as a permutation of I.

(iii) If the χ_i are all nontrivial, we have $\mathsf{R}a_! \xrightarrow{\sim} \mathsf{R}a_*$.

Proof. The scheme $W^*/\mathbb{G}_m$ is the complement of a relative normal-crossings divisor in the scheme Q, which is proper and smooth over $\mathrm{Spec}(A)$, and $\mathscr{K}_n(\chi)$ is locally constant on $W^*/\mathbb{G}_m$ and is tamely ramified along the boundary. Consequently, the $\mathsf{R}^i a_!$ and $\mathsf{R}^i a_*$ are smooth sheaves, compatible with every change of base. A standard argument then reduces us to the case in which A is a finite field, and (i) follows from 4.17 and 4.11(i). To prove (ii), use the compatibility of the action of σ with the isomorphism 4.17, together with 4.12. For (iii), note that if the χ_i are all nontrivial, then $\mathscr{K}_n(\chi)$ on $W^*/\mathbb{G}_m \subset Q$ is ramified along every divisor at infinity, and apply 1.19.1. □

5 Hecke characters

5.1

Let F be a number field (of finite degree over $\mathbb{Q}$) and let k be a field of characteristic 0. Here are several equivalent descriptions of an *algebraic* homomorphism $\alpha : F^\times \to k^\times$.

(i) Let $\{e_i\}$ be a basis of F over $\mathbb{Q}$. The homomorphism α is algebraic if it is given by a formula $\alpha(\sum x^i e_i) = A(x^i)$, $A \in k(X^i)$.

This means that α agrees on $F^\times$ with a rational map defined over k from $\mathrm{R}_{F/\mathbb{Q}}(\mathbb{G}_m)$ to $\mathbb{G}_m$. By the Zariski density of $F^\times$, and because a rational homomorphism is defined everywhere, such a map is a homomorphism of group schemes:

(ii) α is induced by a homomorphism of group schemes over k

$$\mathrm{R}_{F/\mathbb{Q}}(\mathbb{G}_m) \otimes_{\mathbb{Q}} k \to \mathbb{G}_m.$$

If k is a number field, the adjunction property of restriction of scalars R shows that this is equivalent to

(iii) (k a number field) α is induced by a homomorphism of group schemes over $\mathbb{Q}$: $\mathrm{R}_{F/\mathbb{Q}}(\mathbb{G}_m) \to \mathrm{R}_{k/\mathbb{Q}}(\mathbb{G}_m)$.

Let $\bar{k}$ be an algebraic closure of k, and let $I = \hom(F, \bar{k})$. Over $\bar{k}$, the character group of $\mathrm{R}_{F/\mathbb{Q}}(\mathbb{G}_m)$ is $\mathbb{Z}^I$, with basis the embeddings of F into $\bar{k}$. The characters defined over k are those invariant under $\mathrm{Gal}(\bar{k}/k)$; they can be described either as those sending $F^\times$ into $k^\times \subset \bar{k}$, or in terms of orbits of $\mathrm{Gal}(\bar{k}/k)$ on I, which in turn correspond to the factors of $F \otimes k$.

(iv) α is of the form $\alpha = \prod_{\omega \in I} \omega^{n_\omega}$. The allowed families of exponents (n_ω) are those such that $n_\omega = n_{\omega'}$ for ω and ω' in the same orbit of $\mathrm{Gal}(\bar{k}/k)$. Equivalently, these are those such that $\prod_\omega (x)^{n_\omega} \in k$ for every $x \in F$.

(v) Write $F \otimes k = \prod_{j \in J} F_j$, where the F_j are fields. Then α can be written $\alpha = \prod N_{F_j/k}^{m_j}$.

In the special case where k contains a normal closure of F, these expressions become: $\alpha = \prod \omega^{n_\omega}$, where ω runs over the $[F : \mathbb{Q}]$ embeddings of F into k.

5.2

Let k be a number field, and let α be an algebraic homomorphism from $F^\times$ to $k^\times$. There is then a unique homomorphism, also denoted α, of the group $I(F)$ of fractional ideals of F to that of k, such that $\alpha((x)) = (\alpha(x))$. Uniqueness follows from the fact that every ideal a has a power that is principal, and that $I(k)$ is torsion-free. To prove existence, we use for example 5.1(v): we have $\alpha(a) = \prod N_{F_j/k}^{m_j}((a))$.

5.3

Let us recall the definition of algebraic Hecke characters, also called Weil Hecke characters (or grössencharaktere) of type A_0. Let F be a number field, let $\mathfrak{m}$ be an ideal of F (i.e., of the ring of integers of F), let $I_{\mathfrak{m}}$ be the group of fractional ideals of F prime to $\mathfrak{m}$, and let k be a field of characteristic 0. A homomorphism $\chi : I_{\mathfrak{m}} \to k^\times$ is an *algebraic Hecke character* (of conductor $\leqslant \mathfrak{m}$) if there exists an algebraic homomorphism $\chi_{\mathrm{alg}} : F^\times \to k^\times$ satisfying

$$\text{For } x \in F^\times, \text{ prime to } \mathfrak{m}, \text{ totally positive, and } \equiv 1 \pmod{\mathfrak{m}}, \text{ one has } \chi((x)) = \chi_{\mathrm{alg}}(x). \qquad (*)$$

By the density of the set of x in $(*)$, χ_{alg} is entirely determined by χ. This is the *algebraic part* of χ. If $\chi((x)) = \chi_{\mathrm{alg}}(x)$ for x totally positive and $\equiv 1 \pmod{\mathfrak{m}'}$, χ extends to a Hecke character of conductor $\leqslant \inf(\mathfrak{m}, \mathfrak{m}')$: $I_{\mathfrak{m}+\mathfrak{m}'} \to k^\times$. We identify Hecke characters that coincide on their common domain of definition, and we call *conductor* of χ the smallest $\mathfrak{m}'$ such that χ is of conductor $\leqslant \mathfrak{m}'$.

5.4 Remark

If an algebraic Hecke character χ takes its values in a subfield k' of k, it is already a Hecke character with values in k': it suffices to observe that $\chi_{\mathrm{alg}} : \mathrm{R}_{F/\mathbb{Q}}(\mathbb{G}_m) \to \mathbb{G}_m$ is already defined over k', and this follows from the Zariski density in $\mathrm{R}_{F/\mathbb{Q}}(\mathbb{G}_m)$ of the set of totally positive $x \equiv 1 \pmod{\mathfrak{m}}$. We can always take for k' a subfield of k of finite degree over $\mathbb{Q}$.

5.5

If ε is a totally positive unit $\equiv 1 \pmod{\mathfrak{m}}$, we have $\chi_{\mathrm{alg}}(\varepsilon) = \chi((\varepsilon)) = 1$. The homomorphism χ_{alg} therefore factors through the quotient $T_{\mathfrak{m}}$ of $\mathrm{R}_{F/\mathbb{Q}}(\mathbb{G}_m)$ by the Zariski closure of the group $E_{\mathfrak{m}} \subset F^\times$ of totally positive units $\equiv 1 \pmod{\mathfrak{m}}$.

According to Serre [35, II.3], if k is an algebraic closure of $\mathbb{Q}$, and $\mathfrak{m}$ is large enough, the characters $\prod \omega^{n_\omega}$ of $\mathrm{R}_{F/\mathbb{Q}}(\mathbb{G}_m)$ of the form χ_{alg} are characterized as follows: there must exist an integer N, the *weight* of χ (or χ_{alg}), such that for any element σ of $\mathrm{Gal}(k/\mathbb{Q})$ conjugate to complex conjugation, we have $n_\omega + n_{\sigma\omega} = N$. If F_1 is the largest subfield of F which is a quadratic extension that is totally imaginary over a totally real field F_1', this amounts to saying that χ_{alg} is of the form $\chi_1 \circ N_{F/F_1}$, and that $\chi_1 | F_1 = (N_{F_1/\mathbb{Q}})^N$.

If χ is of weight N, for any ideal $\mathfrak{a}$ of F, $\chi(\mathfrak{a})$ is a algebraic number all of whose conjugates have absolute value $N(\mathfrak{a})^{N/2}$ [35, II.3 prop.2].

5.6

For a fixed number field k, additional conditions are imposed on χ_{alg}. For any ideal $\mathfrak{a}$ of F prime to the conductor, we have in fact

$$\chi_{\mathrm{alg}}(\mathfrak{a}) = (\chi(\mathfrak{a})), \qquad (5.6.1)$$

so that $\chi_{\mathrm{alg}}(\mathfrak{a})$ is principal. Since the group of fractional ideals of k is torsion-free, it is enough to prove the n-th power of (5.6.1), for a suitable $n \neq 0$; this allows us to replace $\mathfrak{a}$ by $\mathfrak{a}^n$, therefore to assume $\mathfrak{a} = (x)$, with x totally positive $\equiv 1 \pmod{\mathfrak{m}}$. All that remains is to use the definitions.

Together with 5.5, this shows that χ_{alg} determines the valuations of $\chi(\mathfrak{a})$ at all places of k.

5.7

Serre's group $S_{\mathfrak{m}}$ can be characterized as the group of multiplicative type whose group of characters (on any field) is the group of algebraic Hecke characters of conductor $\leqslant \mathfrak{m}$ (see [35, II 2.1 et 2.2]). Its relation with ℓ-adic representations is explained in [35, II 2.3].

Theorem 5.8 ([35])**.** *Let χ be an algebraic Hecke character of F with values in E_λ, for E_λ a finite extension of $\mathbb{Q}_\ell$. There is then a unique homomorphism $\chi_\lambda : \mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}} \to E_\lambda$, such that*

(i) χ_λ is unramified outside the conductor $\mathfrak{f}$ of χ and outside ℓ.

(ii) For $\mathfrak{p}$ a prime ideal of F prime to $\mathfrak{f}$ and to ℓ, and $F_\mathfrak{p} \in \mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}}$ the geometric Frobenius at $\mathfrak{p}$, we have

$$\chi_\lambda(F_\mathfrak{p}) = \chi(\mathfrak{p}).$$

5.9

At the end of this section, we give a criterion for a λ-adic representation to arise from a Hecke character, and in the next section we apply it to Jacobi sums. We thereby recover, in a somewhat generalized form, Weil's results [42, 44], with the second part of Weil's proof replaced by a ℓ-adic cohomology argument.

Theorem 5.10. *Let F and k be two number fields, let λ be a place of k of residue characteristic ℓ, and let $\chi_\lambda : \mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}} \to k_\lambda^\times$ be a homomorphism, unramified outside ℓ and a finite set S of places. We assume that there exists a set T of places (containing S and the places above ℓ), of density 0, and an algebraic homomorphism $\chi_0 : F^\times \to k^\times$ such that*

(i) For $\bar{k}$ an algebraic closure of k, $\chi_0 : F^\times \to k^\times \hookrightarrow \bar{k}^\times$ is of the type considered in 5.5, of weight N;

(ii) For $\mathfrak{p}$ prime $\notin T$, $\chi_\lambda(F_\mathfrak{p})$ lies in $k^\times$, $(\chi_\lambda(F_\mathfrak{p})) = \chi_0(\mathfrak{p})$, and all complex conjugates of $\chi_\lambda(F_\mathfrak{p})$ have absolute value $(N\mathfrak{p})^{N/2}$.

Then χ_λ is defined (5.8) by an algebraic Hecke character of F with values in k, whose algebraic part is χ_0.

Let χ' be an algebraic Hecke character with values in a finite Galois extension k' of k, of algebraic part χ_0 (5.5). After enlarging T if necessary, we may suppose that the conductor of χ' is supported in T. Let λ' be a place of k' above λ, and let $\chi_{\lambda'}$ be the composite $\mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}} \to k_\lambda^\times \to {k'}_{\lambda'}^\times$, and $\chi'_{\lambda'} : \mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}} \to {k'}_{\lambda'}^\times$ defined by χ' (5.8). Set $\varepsilon = \chi_{\lambda'} \cdot {\chi'}_{\lambda'}^{-1}$.

Hypothesis (ii), together with 5.5, 5.6, and 5.8, ensures that for $\mathfrak{p} \notin T$, we have $\varepsilon(F_\mathfrak{p}) \in {k'}^\times$, and that in every completion of k' this number has absolute value 1. It follows that $\varepsilon(F_\mathfrak{p})$ belongs to the finite group $\boldsymbol{\mu}$ of roots of unity in k'. By the Chebotarev density theorem and the density-zero hypothesis on T, the $F_\mathfrak{p}$ ($\mathfrak{p} \notin T$) are dense in $\mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}}$, so that $\varepsilon(\sigma) \in \mu$ for all $\sigma \in \mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}}$: the character ε is a finite order character $\mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}} \to \mu$. By class field theory, it corresponds to a finite-order character of the idèle class group of F, i.e. to an algebraic Hecke character with trivial algebraic part. After correcting χ' by this character, we are reduced to the case in which $\chi_{\lambda'} = \chi'_{\lambda'}$, and it remains to show that χ', a priori taking values in k', in fact takes values in k. If $\sigma \in \mathrm{Gal}(k'/k)$, χ' and ${\chi'}^\sigma$ coincide on every prime ideal $\mathfrak{p} \notin T$, since $\chi'(\mathfrak{p}) = \chi'_{\lambda'}(F_\mathfrak{p}) = \chi_{\lambda'}(F_\mathfrak{p}) \in k^\times$. The characters $\chi'_{\lambda'}$, and ${\chi'_{\lambda'}}^\sigma$, coincide on a dense subset of $\mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}}$ and hence are equal. Thus $\chi' = {\chi'}^\sigma$, so χ' takes values in k.

6 Hecke characters defined by Jacobi sums

The idea of this section is as follows. Consider a Gauss sum $\tau_{\mathbb{F}_q}(\chi,\psi)$. Both this sum and the corresponding sheaf $\mathscr{F}(\chi^{-1}\psi)$ are tied in two ways to the characteristic p and to the base field $\mathbb{F}_q$:

a) because the additive character ψ and the sheaf (ψ) occur in it;

b) because $\mathscr{F}(\chi)$ is defined from the exact Lang sequence

$$0 \longrightarrow k^\times \longrightarrow V^* \longrightarrow V^* \longrightarrow 0.$$

These present two difficulties if we wish to lift the corresponding cohomological constructions to a number field F and find ℓ-adic representations of $\mathrm{Gal}(\bar{F}/F)$ whose Frobenius eigenvalues are Gauss sums.

If χ is trivial on $\mathbb{F}_q^\times$, the sum $\tau_{\mathbb{F}_q}(\chi,\psi)$ is independent of ψ and is q times a Jacobi sum. The latter is related to the cohomology of $W^*/\mathbb{G}_m$, with coefficients in a sheaf obtained from χ: thus ψ, and with it difficulty a), disappear. To resolve b), it suffices to describe the sheaves in question by means of exact Kümmer sequences (which make sense in every characteristic). This is possible by 4.9.

Once the ℓ-adic representations have been found, we use 5.10 and Stickelberger's theorem to show that they come from algebraic Hecke characters.

6.1

If E is a field with algebraic closure $\bar{E}$, and λ is a character, of order dividing n, of $\mu_d(\bar{E})$, we denote by ${}_n\lambda$ the character of $\mu_n(\bar{E})$ such that λ and ${}_n\lambda$ induce the same character of $\widehat{\mathbb{Z}}(1)_{\bar{E}} = \varinjlim \mu_n(\bar{E})$. The same notation is used when λ is a character of $\widehat{\mathbb{Z}}(1)_{\bar{E}}$.

Let F and k be two number fields, $\bar{F}$ an algebraic closure of F, I a finite set equipped with an action of $\mathrm{Gal}(\bar{F}/F)$ and $\lambda = (\lambda_i)_{i\in I}$ a family of characters $\lambda_i : \widehat{\mathbb{Z}}(1)_{\bar{F}} \to k^\times$. It is assumed that $\lambda_i \neq 1$ $(i \in I)$, that the product of λ_i is trivial and that the family λ is defined over F, i.e. that for every $\sigma \in \mathrm{Gal}(\bar{F}/F)$, we have $\lambda_{\sigma(i)} = \lambda_i \circ \sigma^{-1}$.

The Galois set I is the set of homomorphisms into $\bar{F}$ of an algebra E separable over F. If C is the set of orbits of $\mathrm{Gal}(\bar{F}/F)$ in I, we have a decomposition of E as a product of fields $E = \prod_{\alpha\in C} E_\alpha$, where α is identified with the set of embeddings of E_α in $\bar{F}$. If the characters λ_i, for $i \in \alpha$, are of order d_α, the field E_α contains the d_α-th roots of 1 and there exists $\lambda_\alpha : \mu_{d_\alpha}(E_\alpha) \hookrightarrow k^\times$ such that, if $i \in \alpha$ corresponds to the embedding σ_i of E_α in $\bar{F}$, then ${}_{d_\alpha}\lambda_i = \lambda_\alpha \sigma_i^{-1}$.

6.2

Let $n > 0$ be a multiple of the d_α, let Σ be the set of places of F at which E/F ramifies or which divide n, let μ be a place of k of residue characteristic ℓ, and let A be the ring of elements of F integral outside Σ and ℓ. The integral closure M of A is finite étale of rank $N = |I|$ over A. With the notation of 4.6, 4.8, ${}_n\lambda_i$ define

$${}_n\lambda : (V^*/\mathbb{G}_m)_n \to k^\times \subset k_\mu^\times.$$

Let a be the projection of $W^*/\mathbb{G}_m$ onto $\mathrm{Spec}(A)$. By 4.20, the sheaf $\mathsf{R}^{N-2}a_!\mathscr{K}_n({}_n\lambda)$ is smooth of rank one; it defines an ℓ-adic representation

$$j_\mu[\lambda] : \mathrm{Gal}(\bar{F}/F)^{\mathrm{ab}} \to k_\mu^\times$$

(or simply j_μ) unramified outside σ and ℓ.

6.3

Let us compute $j_\mu(F_\mathfrak{p})$. By 4.20, it suffices to do so after reduction modulo $\mathfrak{p}$. Put $f = A/\mathfrak{p}$, $e = M/\mathfrak{p}M$, and let $\bar{f}$ be the algebraic closure of f determined by a place of $\bar{F}$ above $\mathfrak{p}$. We still have $I = \hom_f(e, \bar{f})$. After reduction, ${}_n\lambda$ still has a description as in 6.1:

a) Let D be the set of orbits of $\mathrm{Gal}(\bar{f}/f)$ in I. The decomposition of e as a product of fields has the form $e = \prod_{\beta\in D} e_\beta$, where σ_i $(i \in \beta)$ are identified with the embeddings of e_β into F. For $\beta \in D$, denote by $\alpha(\beta)$ the element of C containing β, and put $d_\beta = d_{\alpha(\beta)}$. Let

$$\lambda_\beta : \mu_{d_\beta}(e_\beta) \xleftarrow{\sim} \mu_{d_\beta}(E_{\alpha(\beta)}) \xrightarrow{\lambda_{d(\beta)}} k^\times.$$

b) If $i \in I$ corresponds to the embedding σ_i of e_β into $\bar{f}$, the reduction ${}_{d\beta}\bar{\lambda}_i : \mu_{d\beta}(\bar{f}) \to k^\times$ of ${}_{d\beta}\lambda_i$, itself the reduction of ${}_{d\beta}\lambda_i$, is $\lambda_\beta \circ \sigma_i^{-1}$.

Let q_β be the number of elements of e_β, $\chi_\beta =_{(q_{\beta-1})} \lambda_\beta$, and $\chi : e^\times \to k^\times$ the character with coordinates χ_β. On the affine space over $A/\mathfrak{p}$ defined by e (4.6), or rather on the torus $e_\beta^\times$, we have isomorphisms $\mathscr{K}_n((_n\bar{\lambda}_i)_{i\in\beta}) = \mathscr{K}_{d_\beta}((\lambda_\beta \circ \sigma_i^{-1})_{i\in\beta}) = \mathscr{K}_{q_{\beta-1}}((\chi_\beta \circ \sigma_i^{-1})_{i\in I}) = \mathscr{F}(\chi_\beta)$ (4.9). On $e^\times$, we therefore have $\mathscr{K}_n((_n\bar{\lambda}_i)_{i\in\beta}) = \mathscr{F}(\chi)$, and this isomorphism descends to the reduction modulo $\mathfrak{p}$ of $V^*/\mathbb{G}_m$. It follows that

Proposition 6.4. *With the notations of 6.2 and 6.3, $j_\mu(F_\mathfrak{p})$ is the Jacobi sum $J(\chi)$.*

Let us rewrite the formulas linking $(\lambda_i)_{i\in I}$ to $(\chi_\beta)_{\beta\in B}$: for $i \in \beta \subset \alpha$,

$$\begin{aligned} {}_{d_\alpha}\lambda_i &= \lambda_\alpha \circ \sigma_i^{-1} && \lambda_\alpha : \mu_{d_\alpha}(E_\alpha) \to k^\times \\ \lambda_\beta &= \text{reduction of } \lambda_\alpha && : \mu_{d_\alpha}(e_\beta) \to k^\times \\ \chi_\beta &=_{q_{\beta-1}} \lambda_\beta : x \mapsto \lambda_\beta(x^{(q_\beta-1)/d_\alpha}) && : e_\beta^\times \to k^\times \end{aligned}$$

Theorem 6.5. *The representation j_μ is defined by an algebraic Hecke character of F with values in $k^\times$.*

We shall verify this using 5.10. Here we follow Weil's proof [42, 44], using Stickelberger's theorem, and I shall give only a few indications.

6.6

Given $j : \mathrm{Gal}(\bar{F}/F) \to k_\lambda^\times$ and a finite extension F'/F, one verifies using 5.10 that j is defined by a Hecke character if and only if $j|\,\mathrm{Gal}(\bar{F}/F')$ is. This remark allows us, in 6.5, to reduce to the case where Galois acts trivially on I and where F contains the n-th roots of unity. We may then reduce to the case $F = \mathbb{Q}(\sqrt[n]{1})$ and take $k = F$. In this case, each ${}_n\lambda_i$ is defined by $a_i \in \mathbb{Z}/n$: it is $x \mapsto x^{a_i} : \mu_n \to k^\times$. We have $\sum a_i = 0$, and $a_i \neq 0$.

6.7

In a number field, the places of degree greater than 1 always form a set of density 0. By applying 5.10, we may therefore disregard them and use Stickelberger only for a prime field. Let p be prime, let $0 < a < p-1$, and let $\widetilde{x} : \mathbb{F}_p^\times \to \mathbb{Q}_p^\times$ be the "multiplicative lift" character; put $g = -\sum_{x\in\mathbb{F}_p^\times} \widetilde{x}^{-a}\zeta^z \in \mathbb{Q}_p(\zeta)$, for ζ a p-th root of 1. Again denote by x the integer in $[0, p-1]$ lifting x, and expand $\zeta^x = (1+\pi)x$ by the binomial

formula. We find $g = -\sum_{0=0}^{p-1} A_i \pi^i$ with $A_i \in \mathbb{Z}_p$, whose reduction $\bmod p$ is the sum $\sum_{x\in\mathbb{F}_p^\times} x^{-a}\binom{x}{i}$. For b not divisible by $p-1$, we have $\sum_{x\in\mathbb{F}_p^\times} x^b = 0$. If $i < a$, $\binom{x}{i}$ is a polynomial in x of degree $i < a$, whence $A_i \equiv 0 \pmod p$. Likewise, $A_a \equiv \frac{p-1}{a!} \pmod p$, and $g \sim \frac{\pi^a}{a!}$: the valuation of g is given by $v(g)/v(p) = \frac{a}{p-1}$.

6.8

Let σ_i ($i \in (\mathbb{Z}/n)^\times$) be the element of $\mathrm{Gal}(\mathbb{Q}(\sqrt[n]{1})/\mathbb{Q})$ such that $\sigma_i(\zeta) = \zeta^i$ for $\zeta^n = 1$, and write the group of algebraic homomorphisms $\mathbb{Q}(\sqrt[n]{1})^\times \to \mathbb{Q}(\sqrt[n]{1})^\times$ additively. For λ as in 6.6, defined by a family $(a_i)_{i\in I}$ of nonzero integers $\bmod n$ whose sum is zero, 5.10, (4.15.1) and 6.7 show that $j_\mu[\lambda]$ is defined by an algebraic Hecke character $j[a]$ and that, if N denotes the norm, its algebraic part is given by

$$(Nj[a])_{\mathrm{alg}} = \sum_{i\in(\mathbb{Z}/n)^\times} \sum_{j\in I} \left\lfloor \frac{ia_j}{n} \right\rfloor \sigma_i^{-1} \tag{6.8.1}$$

where $\lfloor\cdot\rfloor$ is the fractional part.

6.9

The most interesting case is that in which $F \subset \mathbb{Q}(\sqrt[n]{1})$ and the family of ${}_n\lambda_i$ is constructed as follows:

a) Take a finite family $(Aj)_{j\in J}$ of orbits of $\mathrm{Gal}(\sqrt[n]{1}/F) = H \subset (\mathbb{Z}/n)^\times$ in $\mathbb{Z}/n$. Assume that $A_j \neq \{0\}$ and that $\sum_{j\in J}\sum_{a\in A_j} a = 0$.

b) Take $I = \sqcup_{j\in J} A_j$; Galois acts on each A_j.

c) Take $\bar{F} \supset \mathbb{Q}(\sqrt[n]{1})$, $k = \mathbb{Q}(\sqrt[n]{1})$ and, if $i \in I$ corresponds to $a \in A_j \subset (\mathbb{Z}/n)^\times$, ${}_n\lambda_i(x) = x^a$.

Using 4.20, one verifies that a general j_μ (relative to F_1) is obtained from a j_μ as above (for $F \subset \mathbb{Q}(\sqrt[n]{1})$, with F_1 an extension of F) by restriction to $\mathrm{Gal}(\bar{F}/F_1)$ and multiplication by a character of order two.

For $a \in \mathrm{Gal}(k/\mathbb{Q}) = (\mathbb{Z}/n)^\times$, a transforms the family of A_j into the family of aA_j. If $a \in H$, the family of A_j is therefore preserved, and the $j_\mu(F_\mathfrak{p})$ are invariant under H:

Proposition 6.10. *Under the assumptions of 6.9, j_μ is defined by a character that is an algebraic Hecke character of F with values in F.*

Let us again take $F = \mathbb{Q}(\sqrt[n]{1})$ and consider the Hecke characters $j[a]$ defined by a family $(a_i)_{i\in I}$, $i \in \mathbb{Z}/n$, $a_i \neq 0$, $\sum a_i = 0$. The following theorem was obtained independently by Vishik.

Theorem 6.11. *Every algebraic Hecke character of $\mathbb{Q}(\sqrt[n]{1})$ has a power, with exponent a, in the group generated by the $j[a]$ and the norm.*

Since we work "up to torsion," only the algebraic part of the Hecke characters under consideration matters. Applying (6.8.1) to $j[a]$, with $a =$ an element of $\mathbb{Z}/n$ repeated n times, we are reduced to the following lemma.

Lemma 6.12. *Write $\sum x_j\sigma_j$ for the elements of the group algebra $\mathbb{Q}[(\mathbb{Z}/n)^\times]$, and let x be the subgroup consisting of those for which $x_j + x_{-j} = C\frac{te}{}$. Then X is generated over $\mathbb{Q}$ by $N = \sum\sigma_j$ and by the elements $g_a = \sum \left\lfloor \frac{ia}{n} \right\rfloor \sigma) i^{-1}$ ($a \in \mathbb{Z}/n$, $a \neq 0$).*

Both X and $Y = \langle N, (g_a)\rangle$ are ideals of the group algebra, and it suffices to check that they are annihilated by the same complex characters χ of $(\mathbb{Z}/n)^\times$. This amounts to saying that a odd character ($\chi(j) = -\chi(-j)$) never annihilates all the g_a. If χ is primitive, we have

$$\chi(g_1) = \sum \frac{i}{n}\chi^{-1}(i) = -L(\chi, 0) \neq 0.$$

In the general case, if χ comes from a primitive character of $(\mathbb{Z}/n)^\times$, $\chi(g_{n/d})$ reduces to an analogous sum over $(\mathbb{Z}/n)^\times$, hence the lemma.

7 Generalized Kloosterman sums

7.1

Let $\mathbb{F}_q$ be a finite field with q elements, and let ψ be a nontrivial additive character. In this section, we undertake a cohomological study of generalized Kloosterman sums

$$\mathrm{K}_{n,a} = \sum_{x_1\cdots x_n = a} \psi(x_1 + \cdots + x_n) \qquad (n \geqslant 1). \tag{7.1.1}$$

For $a = 0$, this sum is elementary (see 7.7):

$$\mathrm{K}_{n,0} = (-1)^{n-1}. \tag{7.1.2}$$

The interesting case is $a \neq 0$. The x_i then belong to $\mathbb{F}_q^\times$. In this case we shall prove the bound

$$|K_{n,a}| \leqslant nq^{\frac{n-1}{2}}. \tag{7.1.3}$$

Our essential tools will be the cohomological counterparts of the following identities:

$$\begin{aligned} \mathrm{K}_{n,a} &= \sum_{x_1} \psi(x_i) \sum_{x_2\cdots x_n = a/x_1} \psi(x_2 + \cdots + x_n) \qquad (7.1.4)\\ &= \sum_{x\in\mathbb{F}_q^\times} \psi(x)\mathrm{K}_{n-1,a/x} \qquad (a \neq 0, n \geqslant 2) \\ \sum_a \mathrm{K}_{n,a} &= \sum_a \sum_{x_1\cdots x_n = a} \psi\left(\sum x_i\right) = \sum_{x_1,\ldots,x_n} \psi\left(\sum x_i\right) = 0 \qquad (7.1.5) \end{aligned}$$

For χ a nontrivial character of $\mathbb{F}_q^\times$,

$$\sum \chi(a)\mathrm{K}_{n,a} = \sum_{x_1,\ldots,x_n} \chi\left(\prod x_i\right)\cdot\psi\left(\sum x_i\right) = (-\tau(\chi^{-1}, \psi))^n \tag{7.1.6}$$

(Gauss sum).

7.2

Let k be an étale algebra of degree n over $\mathbb{F}_q$, and let $\varepsilon(k)$ be as in (4.5.1). Put

$$\mathrm{K}_{k,a} = \sum_{N_{k/\mathbb{F}_q}(x) = a} \psi\,\mathrm{tr}(x).$$

We likewise have

$$\mathrm{K}_{k,0} = (-1)^{n-1} \cdot \varepsilon(k) \tag{7.2.1}$$

$$\sum_a \mathrm{K}_{k,a} = 0 \tag{7.2.2}$$

$$\sum_a \chi(a)\mathrm{K}_{k,a} = (-1)^n \tau_{\mathbb{F}_q}\left(\chi^{-1} \circ N_{k/\mathbb{F}_q}, \psi\right). \tag{7.2.3}$$

By Fourier inversion on $\mathbb{F}_q^\times$, we deduce an expression of $\mathrm{K}_{k,a}$ in terms of Gauss sums:

$$\mathrm{K}_{k,a} = \frac{1}{q-1}\sum_\chi \chi(a) \sum_{b\in\mathbb{F}_q^\times} \chi^{-1}(b)\mathrm{K}_{k,b}$$

$$(-1)^n\mathrm{K}_{k,a} = \frac{1}{q-1}\left(\varepsilon(k) + \sum_{\chi\neq 1} \chi(a)\tau_{\mathbb{F}_q}\left(\chi \circ N_{k/\mathbb{F}_q}, \psi\right)\right). \tag{7.2.4}$$

The Hasse–Davenport identity now makes it possible to compare $\mathrm{K}_{k,a}$ with $\mathrm{K}_{n,a} = \mathrm{K}_{\mathbb{F}_{q^n},a}$:

$$\mathrm{K}_{k,a} = \varepsilon(k)\mathrm{K}_{n,a}. \tag{7.2.5}$$

I know of no cohomological interpretation of (7.2.4), but I shall give one for (7.2.5). Let us return to the sums $\mathrm{K}_{n,a}$.

7.3

Let $\mathbb{F}$ be an algebraic closure of $\mathbb{F}_q$ and, for $a \in \mathbb{F}$, let V_a^{n-1}, or simply V_a, be the hypersurface in $\mathbb{A}^n$ with equation $x_1 \cdots x_n = a$. As usual, we shall regard ψ as taking ℓ-adic rather than complex values. With the notation of 1.8(ii), (7.1.3) follows from

Theorem 7.4. *The cohomology of V_a^{n-1} with coefficients in $\mathscr{F}(\psi(\sum x_i))$ satisfies*

(i) $\mathrm{H}_c^i = 0$ *for* $i \neq n-1$;

(ii) $\mathrm{H}_c^\bullet \xrightarrow{\sim} \mathrm{H}^\bullet$;

(iii) for $a \neq 0$, $\dim \mathrm{H}_c^{n-1} = n$;

(iv) for $a = 0$, H_c^{n-1} *is canonically isomorphic to* E_λ.

7.5

As usual, this theorem also controls the dependence of $\mathrm{K}_{n,a}$ on q: for each $a \in \mathbb{F}_q^\times$, there are n Frobenius eigenvalues $\alpha_1, \ldots, \alpha_n$, of complex absolute value $q^{\frac{n-1}{2}}$, such that

$$\sum_{\substack{x_1\cdots x_n = a \\ x_i \in \mathbb{F}_{q^m}}} \psi \circ \mathrm{tr}\left(\sum x_i\right) = (-1)^{n-1}\left(\alpha_1^m + \cdots + \alpha_n^m\right).$$

For even n, $x \mapsto -x$ is an involution of V_a, which transforms $\mathscr{F}(\psi)$ into its dual. Arguing as in 3.6, we deduce a canonical nondegenerate alternating form on $\mathrm{H}_c^{n-1}(V_a, \mathscr{F}(\psi))$, with values in $\mathbb{Q}_\ell(-(n-1))$, and hence the following.

Corollary 7.6. *With the notations of 7.5, if n is even, the α_i group together into $\frac{n}{2}$ pairs of roots $\alpha, \bar{\alpha}$ whose product is q^{n-1}.*

7.7

Let us verify the case $a = 0$ of 7.5. The hypersurface V_0 is the union of the coordinate hyperplanes $x_i = 0$. Let us compute the Leray spectral sequence (2.6.1*) for this covering of V_0, for cohomology with or without supports and with coefficients in $\mathscr{F}(\psi)$. By 2.7*, all the initial terms vanish except the cohomology of the intersection $\{0\}$ of all the coordinate hyperplanes. What remains is an isomorphism $\mathrm{H}^0_c \xrightarrow{\sim} \mathrm{H}^0 = E_\lambda$ which justifies 7.4.

We shall prove 7.4 and 7.8 below by simultaneous induction on n, using the spectral sequence of which (7.1.4) is the counterpart. This requires control, as a varies, of $\mathrm{K}_{n,a}$.

Let $\pi : \mathbb{A}^n \to \mathbb{A}$ be the map "product of the coordinates," and let σ be the sum of the coordinates. The hypersurfaces V_a are the fibers of π.

Theorem 7.8. *(i) The sheaf $\mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma)$ is smooth of rank n on $\mathbb{A}^1 \smallsetminus \{0\}$.*

(ii) Its extension by 0 to $\mathbb{P}^1$ is the direct image of its restriction to $\mathbb{A}^1 \smallsetminus \{0\}$.

(iii) At 0, the monodromy is unipotent, with a single Jordan block.

(iv) At ∞, wild inertia acts without fixed points $\neq 0$, and the Swan conductor is 1.

(v) We have $\mathsf{R}^i\pi_!\mathscr{F}(\psi\sigma) \xrightarrow{\sim} \mathsf{R}^i\pi_*\mathscr{F}(\psi\sigma)$ (zero for $i \neq n-1$).

Proof. that 7.4 (for a given value of n) implies 7.8 (for the same value of n).

The fiber of $\mathsf{R}^i\pi_!\mathscr{F}(\psi\sigma)$ at a is $\mathrm{H}^i_c(V_a, \mathscr{F}(\psi\sigma))$, and on the dense open subset of $\mathbb{A}^1$ where the $\mathsf{R}^i\pi_!\mathscr{F}(\psi^{-1}\sigma)$ are locally constant, the fiber of $\mathsf{R}^i\pi_*\mathscr{F}(\psi\sigma)$ is $\mathrm{H}^i(V_a, \mathscr{F}(\psi\sigma))$ (Finiteness Theorem 2.1). The hypothesis 7.4(n) therefore gives us the following.

Lemma 7.9. *(i) $\mathsf{R}^i\pi_!\mathscr{F}(\psi\sigma) = 0$ for $i \neq n-1$.*

(ii) For $i = n-1$, the fiber of this sheaf at any point $a \neq 0$ has constant rank n. At 0, it has rank 1.

(iii) On a dense open U, we have $\mathsf{R}^i\pi_!\mathscr{F}(\psi) \xrightarrow{\sim} \mathsf{R}^i\pi_*\mathscr{F}(\psi)$.

7.10

We shall now use the Leray spectral sequence of π for cohomology with or without compact supports, with coefficients in $\mathscr{F}(\psi\sigma)$. The abutment is known: $\mathrm{H}^\bullet_c(\mathbb{A}^n, \mathscr{F}(\psi\sigma)) = \mathrm{H}^\bullet(\mathbb{A}^n, \mathscr{F}(\psi\sigma)) = 0$ (2.7*). For cohomology with compact supports, 7.9(i) ensures that $E_2^{pq} = 0$ for $q \neq n-1$. The terms E_2 are therefore all zero:

$$\mathrm{H}^p_c(\mathbb{A}^1, \mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma)) = 0. \tag{7.10.1}$$

For $p = 0$, this means that $\mathsf{R}^{n-1}\pi+!\mathscr{F}(\psi\sigma)$ has no sections with point support. In view of the constancy of rank in 7.9(ii), we obtain

$$\begin{array}{l}\text{The sheaf } \mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma) \text{ on } \mathbb{A}^1 \text{ is smooth on } \mathbb{A}^1 \smallsetminus \{0\}, \text{ and is} \\ \text{a subsheaf of the direct image } \mathscr{G} \text{ of its restriction to } \mathbb{A}^1 \smallsetminus \{0\}.\end{array} \tag{7.10.2}$$

The long exact cohomology sequence of

$$0 \longrightarrow \mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma) \longrightarrow \mathscr{G} \longrightarrow \mathscr{Q} \longrightarrow 0.$$

where the support of $\mathscr{Q}$ is concentrated at 0, gives

$$\mathrm{H}^0_c(\mathbb{A}^1, \mathscr{G}) \longrightarrow \mathscr{Q}_0 \longrightarrow \mathrm{H}^1_c(\mathbb{A}^1, \mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma)).$$

Since the outer terms vanish, $\mathscr{Q} = 0$ and

$$\mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma) \text{ is the direct image of its restriction to } \mathbb{A}^1 \smallsetminus \{0\}. \tag{7.10.3}$$

Let j be the inclusion of $\mathbb{A}^1$ into $\mathbb{P}^1$. The "derived-category version" of the Leray spectral sequences is

$$\mathsf{H}^\bullet(\mathbb{P}^1, j_!\mathsf{R}\pi_!\mathscr{F}(\psi\sigma)) = \mathsf{H}^\bullet_c(\mathbb{A}^1, \mathsf{R}\pi_!\mathscr{F}(\psi\sigma)) = \mathrm{H}^\bullet_c(\mathbb{A}^n, \mathscr{F}(\psi\sigma)) = 0$$
$$\mathsf{H}^\bullet(\mathbb{P}^1, \mathsf{R}j_*\mathsf{R}\pi_*\mathscr{F}(\psi\sigma)) = \mathsf{H}^\bullet(\mathbb{A}^1, \mathsf{R}\pi_*\mathscr{F}(\psi\sigma)) = \mathrm{H}^\bullet(\mathbb{A}^n, \mathscr{F}(\psi\sigma)) = 0.$$

Let Δ be the mapping cylinder of $j_!\mathsf{R}\pi_!\mathscr{F}(\psi\sigma) \to \mathsf{R}j_*\mathsf{R}\pi_*\mathscr{F}(\psi\sigma)$. According to 7.9(iii), the cohomology sheaves of this complex of sheaves have finite support. On the other hand, the long exact sequence in cohomology of the triangle $(j_!\mathsf{R}\pi_!\mathscr{F}(\psi\sigma), \mathsf{R}j_*\mathsf{R}\pi_*\mathscr{F}(\psi\sigma), \Delta)$ shows that $\mathsf{H}^\bullet(\mathbb{P}^1, \Delta) = 0$. We have $\mathsf{H}^\bullet(\mathbb{P}^1, \Delta) = \mathrm{H}^0(\mathbb{P}^1, \mathscr{H}^\bullet(\Delta))$, and finally $\Delta = 0$:

$$j_!\mathsf{R}\pi_!\mathscr{F}(\psi\sigma) \xrightarrow{\sim} \mathsf{R}j_*\mathsf{R}\pi_*\mathscr{F}(\psi\sigma).$$

In particular, $\mathsf{R}\pi_!\mathscr{F}(\psi\sigma) \xrightarrow{\sim} \mathsf{R}\pi_*\mathscr{F}(\psi\sigma)$ and, since these complexes of sheaves have only one nonzero cohomology sheaf,

$$j_!\mathsf{R}\pi_!\mathscr{F}(\psi\sigma) \xrightarrow{\sim} j_*\mathsf{R}\pi_!\mathscr{F}(\psi\sigma). \tag{7.10.4}$$

This completes the proof of (i)(ii)(v).

7.11

Let Sw_0 and Sw_∞ be the Swan conductors at 0 and at ∞ of $\mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma)$. We have $\chi_c(\mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma)) = 0$ (7.10.1) and the formula of Euler–Poincaré (3.2.1) reduces to

$$\mathrm{Sw}_0 + \mathrm{Sw}_\infty = 1: \tag{7.11.1}$$

one of these conductors is 0 (tame ramification), and the other is 1.

7.12

Let $\mathscr{G}$ be a sheaf of rank 1 on $\mathbb{G}_m$, of Kummer type 4.7 ($\mathscr{G} = \mathscr{K}_n(\chi)$) and nonconstant ($\chi \neq 1$). The sheaf $\mathscr{F}(\psi\sigma) \otimes \pi^*\mathscr{G}$ on $V^* = \pi^{-1}(\mathbb{G}_m) = \mathbb{A}^n \smallsetminus \pi^{-1}(0)$ is then of the type encountered in the study of Gauss sums, and 4.11(ii) gives us

$$\mathrm{H}^\bullet_c(V^*, \pi^*\mathscr{G} \otimes \mathscr{F}(\psi\sigma)) \xrightarrow{\sim} \mathrm{H}^\bullet(V^*, \pi^*\mathscr{G} \otimes \mathscr{F}(\psi\sigma)). \tag{7.12.1}$$

The Leray spectral sequence of π transforms this statement into

$$\mathrm{H}^\bullet_c(\mathbb{G}_m, \mathscr{G} \otimes \mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma)) \xrightarrow{\sim} \mathrm{H}^\bullet(\mathbb{G}_m, \mathscr{G} \otimes \mathsf{R}^{n-1}\pi_*\mathscr{F}(\psi\sigma)). \tag{7.12.2}$$

Let i be the inclusion of $\mathbb{G}_m$ into $\mathbb{P}^1$, and let Δ be the mapping cylinder of $\delta : i_!(\mathscr{G} \otimes \mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi)) \to \mathsf{R}i_*(\mathscr{G} \otimes \mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma))$ (where $\mathsf{R}^{n-1}\pi_! = \mathsf{R}^{n-1}\pi_*$). Reasoning as in 7.10, we deduce from (7.12.2) that $\Delta = 0$. In particular

$$\text{At 0 and at } \infty, \text{ inertia acts without fixed points} \neq 0 \text{ on } \mathscr{G} \otimes \mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma). \tag{7.12.3}$$

At ∞, this holds even if $\mathscr{G}$ is trivial (7.10.4), so wild inertia acts without a fixed point. In particular, the ramification is wild: by 7.11, we have $\mathrm{Sw}_\infty = 1$, and the ramification at 0 is tame.

At 0, (7.12.3) forces the ramification – which is tame – of $\mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma)$ to be unipotent. By (7.10.3) and 7.9(ii), there is a single Jordan block. This completes the proof of 7.8(n).

7.13

For $n = 1$, 7.4 is trivial. To complete the proof of 7.4 and 7.8, we still have to prove that 7.8, for a given value of n, implies 7.4 for $n + 1$. The case $a = 0$ having been treated (7.7), we assume that $a = 0$. We shall write $x_0, \dots, x_n$ for the coordinates of $\mathbb{A}^{n+1}$. Let $g = x_0 : V_a \to \mathbb{G}_m$, τ the involution $x \mapsto ax^{-1}$ of $\mathbb{G}_m$, and let π, as above, be the product of the coordinates: $\mathbb{A}^{n+1} \to \mathbb{A}^1$, with σ their sum. We shall denote by $\mathscr{F}(\psi\sigma)$ the sheaf $\mathscr{F}(\psi(\sum x_i))$ both on $\mathbb{A}^{n+1}$ and on $\mathbb{A}^n$.

7.14

Let us write down the Leray spectral sequence for g. Since the sheaf $\mathscr{F}(\psi\sigma)$ on $\mathbb{A}^{n+1}$ is the external tensor product of the sheaves $\mathscr{F}(\psi)$ on $\mathbb{A}^1$ and $\mathscr{F}(\psi\sigma)$ on $\mathbb{A}^n$, we find (cf. (7.1.4)).

$$'E_2^{pq} = \mathrm{H}_c^p(\mathbb{G}_m, \mathscr{F}(\psi) \otimes \tau^* \mathsf{R}^q\pi_! \mathscr{F}(\psi\sigma)) \Rightarrow \mathrm{H}_c^{p+q}(V_a, \mathscr{F}(\psi\sigma))$$
$$''E_2^{pq} = \mathrm{H}^p(\mathbb{G}_m, \mathscr{F}(\psi) \otimes \tau^* \mathsf{R}^q\pi_* \mathscr{F}(\psi\sigma)) \Rightarrow \mathrm{H}^{p+q}(V_a, \mathscr{F}(\psi\sigma)).$$

By hypothesis, $\mathsf{R}^q\pi_!\mathscr{F}(\psi\sigma) \xrightarrow{\sim} \mathsf{R}^q\pi_*\mathscr{F}(\psi\sigma)$, and this sheaf is zero for $q \neq n-1$. The sheaf $\mathscr{F}(\psi)$ on $\mathbb{G}_m$ is wildly ramified at ∞ and unramified at 0, while $\tau^*\mathsf{R}^q\pi_!\mathscr{F}(\psi\sigma)$ is wildly ramified at 0 (without invariants under wild inertia, and with Swan conductor 1) and tamely ramified at ∞. Their tensor product is therefore

a) wildly ramified at 0 and ∞, without invariants under wild inertia;

b) of Swan conductor 1 at 0 and n (the rank of $\mathsf{R}^q\pi_!\mathscr{F}(\psi)$) at ∞.

We have ${}'E_2^{pq} \xrightarrow{\sim} {}''E_2^{pq}$, and ${}'E_2^{pq} = 0$ except for $p = 1$ and $q = n-1$. The Euler-Poincaré formula finally gives

$$\dim {}'E_2^{pq} = 1 + n;$$

this completes the proof. □

7.15 Remark

The isomorphism obtained in 7.14

$$\mathrm{H}_c^n(V_a^n, \mathscr{F}(\psi\sigma)) = \mathrm{H}_c^1(\mathbb{G}_m, \mathscr{F}(\psi) \otimes \tau^* \mathsf{R}^{n-1}\pi_! \mathscr{F}(\psi\sigma)) \tag{7.15.1}$$

allows us, with the notation of 7.5, to calculate the product $\det(F)$ of the Frobenius eigenvalues α_i. The formalism of [13] applies, since $\mathscr{F}(\psi)$ and $\mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi\sigma)$ belong to infinite compatible systems of ℓ-adic representations. This reduces us to local problems, which can be simplified by noting that (cf. [13, 9.5])

a) the global constants for $\mathscr{F}(\psi)$ and $\tau^*\mathsf{R}^{n-1}\pi_!\mathscr{F}(\psi)$ are easy to calculated easily, since the cohomology of these sheaves is elementary.

b) at every point, for either of these sheaves, the corresponding ℓ-adic representation of the decomposition group has unramified semisimplification.

The result, for the sum with n variables, is that

$$\det\left(F, \mathrm{H}_c^{n-1}(V_a^{n-1}, \mathscr{F}(\psi))\right) = q^{\frac{n(n-1)}{2}}. \tag{7.15.2}$$

7.16 Remark

For $p = 2$, the sheaf (ψ) is orthogonal. For $a \neq 0$ and n odd, we deduce from 7.4(ii) and Poincaré duality a symmetric bilinear form on $\mathrm{H}_c^{n-1}(V_a^{n-1}, \mathscr{F}(\psi))$ with values in $\bar{\mathbb{Q}}_\ell(1-n)$. With respect to this form, F is an orthogonal similitude of multiplier q^{n-1}, and $q^{\frac{1-n}{2}}F$ belongs to the special orthogonal group, by (7.15.2). One of the eigenvalues of F is therefore $q^{\frac{1-n}{2}}$, and the others occur in pairs of roots α, $\bar{\alpha}$ whose product is q^{n-1}.

For $n = 3$, L. Carlitz [8] obtained a more precise result, equivalent to the following proposition.

Proposition 7.17. *For $p = 2$, and $\psi(x) = (-1)^{\mathrm{tr}_{\mathbb{F}_q/\mathbb{F}_q}(x)}$, we have an isomorphism*

$$\mathrm{H}_c^2(V_a^2, \mathscr{F}(\psi\sigma)) = \mathrm{Sym}^2 \mathrm{H}_c^1(V_a^1, \mathscr{F}(\psi\sigma)).$$

The second tensor power of $\mathrm{H}_c^1(V_a^1, \mathscr{F}(\psi\sigma))$ is $\mathrm{H}_c^1(V_a^1 \times V_a^1, \mathscr{F}(\psi\sigma) \boxtimes \mathscr{F}(\psi\sigma))$ (Künneth), with the symmetry $x \otimes y \mapsto y \otimes x$ represented geometrically by $-\tau^*$, where τ is the automorphism $(x, y) \mapsto (y, x)$ of $V_a \times V_a$. If X' is the quotient of $V_a^1 \times V_a^1$ by $\{\mathrm{id}, \tau\}$ and π is the projection of $V_a^1 \times V_a^1$ onto X', the group $\mathrm{Sym}^2 \mathrm{H}_c^1(V_a^1, \mathscr{F}(\psi\sigma))$ is therefore identified with the cohomology of X' with coefficients in the part anti-invariant under τ of $\pi_*(\mathscr{F}(\psi\sigma) \boxtimes \mathscr{F}(\psi\sigma))$. Denote by s the function on X' such that $s\pi = \sigma\mathrm{pr}_1 + \sigma\mathrm{pr}_2$. We have $\mathscr{F}(\psi\sigma) \boxtimes \mathscr{F}(\psi\sigma) = \mathscr{F}(\psi(\sigma\mathrm{pr}_1 + \sigma\mathrm{pr}_2)) = \mathscr{F}(\psi s\pi) = \pi^*\mathscr{F}(\psi s)$ (an isomorphism compatible with τ). On the image $\pi(\Delta)$ of the diagonal, the desired sheaf of anti-invariants is therefore zero, while on the complement $X = X' \smallsetminus \pi(\Delta)$ it is the tensor product of $\mathscr{F}(\psi s)$ by $\varepsilon(P)$, where ε is the unique character of order 2 of $\{1, \tau\}$, and P the $\{1, \tau\}$-torsor on X given by the double covering induced by $V_a^1 \times V_a^1$. We have

$$\mathrm{Sym}^2 \mathrm{H}_c^1(V_a^1, \mathscr{F}(\psi\sigma)) = \mathrm{H}_c^2(X, \mathscr{F}(\psi\sigma) \otimes \varepsilon(P)). \tag{7.17.1}$$

Let us compute X, s and $\varepsilon(P)$. On $V_a^1 \times V_a^1$, put $x_1 = x_1 \circ \mathrm{pr}_1$, $x_2 = x_2 \circ \mathrm{pr}_2$, $x_1' = x_1 \circ \mathrm{pr}_2$, $x_2' = x_2 \circ \mathrm{pr}_2$. We have $x_1x_2 = x_1'x_2' = a$. Identify functions on X' with functions on X invariant under τ. Let $s_1 = x_1 + x_1'$, $s_2 = x_2 + x_2'$, $p_1 = x_1x_1'$, $p_2 = x_2x_2'$. We have $s_1p_2 = as_2$, $s_2p_1 = as_1$ and X is defined in X' by $s_1 \neq 0$, $s_2 \neq 0$. On X, we therefore have $p_1 = as_1s_2^{-1}$, and (s_1, s_2) identifies x with $\mathbb{G}_m \times \mathbb{G}_m$. On X, the covering P has equation $T^2 - s_1T + as_1s_2^{-1}$ (take T to be the coordinate x_1). If $T = s_1t$, this is rewritten $t^2 - t + as_1^{-1}s_2^{-1}$. We therefore have $\varepsilon(P) = \mathscr{F}(\psi(as_1^{-1}s_2^{-1}))$. Since $s = s_1 + s - 2$, we have $\mathscr{F}(\psi s) \otimes \varepsilon(P) = \mathscr{F}(\psi(s_1 + s_2 + as_1^{-1}s_2^{-1}))$ and the right-hand side of (7.17.1) is identified with the left-hand side of 7.17.

Remark $\mathrm{H}_c^1(V_a^1, \mathscr{F}(\psi\sigma))$ is also the first cohomology group of the elliptic curve obtained by completing the affine curve with equations

$$y^2 - y = x_1 + x_2$$
$$x_1x_2 = a;$$

its modular invariant is $j = a^{-2}$.

7.18 Remark

For χ a multiplicative character of $\mathbb{F}_q^\times$, and $a \neq 0$, the method of 7.14 applies to the study of the sum

$$s = \sum_{x_0 \cdots x_n = a} \chi(x_0)\psi(x_0 + \cdots + x_n)$$

(replace the sheaf $\mathscr{F}(\psi)$ on $\mathbb{G}_m$ by $\mathscr{F}(\chi \cdot \psi)$). We again find a cohomology group of dimension $n + 1$, and $|S| \leqslant (n + 1)q^{n/2}$. Such sums were considered by Salie and Mordell [28].

One may hope that our methods make it possible to study the sums

$$S_{k,\chi,a} = \sum_{N(x)=a} \chi(x)\psi\,\mathrm{tr}(x)$$

(k an étale algebra over $\mathbb{F}_q$, $a \in \mathbb{F}_q^\times$, χ a character of $k^\times$). The analog of 7.4 (for $a \neq 0$) should be true.

7.19

The symmetric group S_n acts on $\mathbb{A}^n$, preserving V_a and the map σ, and hence also the sheaf $(\psi\sigma)$, the inverse image under σ of the sheaf (ψ) on $\mathbb{G}_a$. It therefore acts on $\mathrm{H}_c^{n-1}(V_a, \mathscr{F}(\psi\sigma))$. Formula (7.2.5) admits the following cohomological interpretation.

Proposition 7.20. *The action of S_n on $\mathrm{H}_c^{n-1}(V_a, \mathscr{F}(\psi\sigma))$ is multiplication by the sign character.*

It suffices to show that a transposition τ acts by multiplication by -1. Since $\tau^2 = 1$, the only possible eigenvalues of τ are ± 1. Let V_a/τ be the quotient of V_a for $\{\mathrm{id}, \tau\}$. The map σ, and hence the sheaf $(\psi\sigma)$, descend to the quotient, and the subspace of $\mathrm{H}_c^{n-1}(V_a, \mathscr{F}(\psi))$ fixed by τ is $\mathrm{H}_c^{n-1}(V_a/\tau, \mathscr{F}(\psi\sigma))$. We must prove that this cohomology is zero.

Suppose $a \neq 0$. For $\tau = (1,2)$ the quotient V_a/τ is identified with $\mathbb{G}_a \times \mathbb{G}_m^{n-2}$, the quotient map being $(x_1, x_2, x_3, \ldots, x_n) \mapsto (x_1 + x_2, x_3, \ldots, x_n)$. Indeed, x_1 and x_2 are determined up to order by $x_1 + x_2$ and $x_1 x_2 = a/x_3 \cdots x_n$. In the coordinates $(t, x_3, \ldots, x_n)$, the sheaf takes the form $\mathscr{F}(\psi(t + x_3 + \cdots + x_n)) = \mathscr{F}(\psi(t)) \otimes \mathscr{F}(\psi(x_3 + \cdots + x_n))$. The Künneth formula and $\mathrm{H}_0^\bullet(\mathbb{G}_a, \mathscr{F}(\psi)) = 0$ therefore give the required vanishing.

For $a = 0$, we can deduce 7.20 from calculation 7.7.

7.21

The sums $\mathrm{K}_{n,a}$ in this section were studied by S. Sperber, in his thesis, and in [38] by methods p-adic methods inspired by Dwork and by Bombieri's article [6]. For $p \neq 2$, these methods determine the dependence on q in 7.5, the functional equation $\alpha_i = q^{n-1}\beta_i^{-1}$ between the Frobenius eigenvalues for the sums $\mathrm{K}_{n,a}$ and $\mathrm{K}_{n,b}$ if $b = (-1)^n a$ (see 7.6), and the value 7.15 of the product of the roots. For $p \geqslant n+3$, they also determine the p-adic valuations of the roots. The result is very beautiful: if we arrange the roots α_i in a suitable order, with $0 \leqslant i \leqslant n$, $\alpha_i q^{-i}$ are units. The restrictions on p are probably not essential.

8 Other applications

8.1

The identity 1.9.4 can sometimes be used to calculate the number of rational points of an algebraic variety over $\mathbb{F}_q$. In most cases where an exact result has been obtained, cohomology is expressed in terms of algebraic cycles; this is the case for rational surfaces, quadrics, smooth intersections of two quadrics of odd dimension, flag varieties.... This is not, however, always the case; in Lusztig's beautiful article [27], algebraic cycles do not appear.

8.2

For reductive groups, cohomology can be calculated by lifting to characteristic 0: if B is a Borel subgroup of G, G is a B-torsor over G/B; the cohomology of the smooth projective variety G/B is invariant under

specialization, and we use the Leray spectral sequence of $G \to G/B$ to prove the same result for G. It can be expressed conveniently in terms of *the* maximal torus T of G and the action *of the* Weyl group W on T (for the definition *of the* maximal torus, cf. [7, VIII §2 Rem.2] or [10, p.105]). It is the exterior algebra on its primitive part, which agrees up to a shift with the quotient $I(\mathrm{H}^\bullet(BG, \mathbb{Q}_\ell))$ of the cohomology of BG formed by the "indecomposable elements," and $\mathrm{H}^\bullet(BG, \mathbb{Q}_\ell) = \mathrm{H}^\bullet(BT, \mathbb{Q}_\ell)^W$. If X is the group of characters of T, we have altogether

$$\mathrm{H}^\bullet(G, \mathbb{Q}_\ell) = \bigwedge \left(I \left(\mathrm{Sym}^\bullet(X \otimes \mathbb{Q}_\ell(-1))^W \right) [-1] \right).$$

If G is defined over a finite field $\mathbb{F}_q$, $\mathrm{Gal}(\mathbb{F}/\mathbb{F}_q)$ acts on X and this isomorphism is Galois-compatible. Passing to cohomology with compact supports, we recover the classical formulas for the number of rational points of G. If $F^* : X \to X$ is defined by the Frobenius morphism $F : T \to T$, and $\deg_G(F)$ is the degree $q^{\dim G}$ of $F : G \to G$, we have

$$|G_0(\mathbb{F}_q)| = \deg_G(F) \cdot \det \left(1 - {F^*}^{-1}, I(\mathrm{Sym}^\bullet(X \otimes \mathbb{Q})^W) \right). \tag{8.2.1}$$

The same formula applies to the Ree and Suzuki groups; these groups are of the form G^F (reductive G, F^2 a Frobenius), and it suffices to verify that the Lefschetz trace formula holds for F acting on G. If B is a Borel subgroup stable by F, we verify it directly for F acting on B; for the action on G/B, which is proper and smooth, we can invoke the general theorems.

8.3

The trace formula was used by Deligne–Lusztig [10], Kazhdan [25] and Springer [39] in the study of complex representations of finite groups $G_0(\mathbb{F}_q)$, for G_0 reductive over $\mathbb{F}_q$. The work of Kazhdan and Springer contains admirable examples of how the trace formula permits "analytic continuation" from a split situation to a nonsplit situation (see 1.13).

Chapter 7

Finiteness theorems in ℓ-adic cohomology

1 Statement of the theorems

Throughout this exposé, S will be a Noetherian scheme and A a left Noetherian torsion ring annihilated by an integer invertible on S. Our main result is the following.

Theorem 1.1. *Suppose that S is regular of dimension 0 or 1. Let $f : X \to Y$ be a morphism of S-schemes of finite type, and let $\mathscr{F}$ be a constructible sheaf of left A-modules on X. Then the sheaves $\mathsf{R}^i f_* \mathscr{F}$ are constructible.*

The proof will be given in Section 2 and in 3.10.

1.2 Remark

In characteristic 0, this result is less general than [2, XIX paragraphe 5], which proves the conclusion of the theorem for every morphism of finite type of excellent schemes of characteristic 0. The proof of [2, XIX] uses, on the one hand, resolution of singularities and, on the other, the assumption that the schemes have equal characteristic (in order to deduce the "purity theorem" from resolution).

1.3 Remark

We shall say that a complex $K \in \mathrm{Ob}\,\mathsf{D}(X, A)$ is *constructible* if its cohomology sheaves are constructible, and shall use a subscript c for the subcategory of $\mathsf{D}(X, A)$ (or D^+, D^-, D^b) consisting of constructible complexes. In the language of derived categories, which we shall use freely, 1.1 says that $\mathsf{R}f_* : \mathsf{D}^+(X, A) \to \mathsf{D}^+(Y, A)$ sends D^+_c into D^+_c. More explicitly:

a) For K concentrated in a sheaf $\mathscr{F}$ in degree 0, one has $\mathscr{H}^i \mathsf{R}f_* K = \mathsf{R}^i f_* \mathscr{F}$; the derived statement therefore implies the theorem.

b) Conversely, one invokes the spectral sequence

$$E_1^{pq} = \mathsf{R}^q f_* \mathscr{H}^p(K) \Rightarrow \mathscr{H}^{p+q} \mathsf{R}f_* K.$$

Speaking the language of derived categories has the advantage of replacing, by the simple transitivity formula $\mathsf{R}(fg)_* = \mathsf{R}f_*\mathsf{R}g_*$, the Leray spectral sequence $E_2^{pq} = \mathsf{R}^p f_* \mathsf{R}^q g_* \Rightarrow \mathsf{R}^{p+q}(fg)_*$.

Under the hypotheses of 1.1, it follows from [2] that $\mathsf{R}f_*$ has finite cohomological dimension. This makes it possible above to replace D^+ by D, D^-, or D^b.

1.4 Ideas of the proof

a) Poincaré duality treats the case where X is smooth, $\mathscr{F}$ is locally constant, and $Y = S$. The dimension hypothesis is seen naïvely when calculating the $\mathsf{R}\mathscr{H}om$ on S.

b) Factor f as gj: g proper and j an open immersion. One has $\mathsf{R}f_* = \mathsf{R}g_*\mathsf{R}j_*$, and the finiteness theorem for proper morphisms controls $\mathsf{R}g_*$. By dévissage, one reduces to assuming that x is smooth, $\mathscr{F}$ is locally constant, f is an open immersion, and Y is proper over S.

c) Naively, an induction on $\dim X$ (with a change of S) makes it possible to suppose that the theorem is true outside a part of Y finite over S. Denoting the structure morphisms by $a : X \to S$ and $b : Y \to S$, one then shows that if the theorem were false for $\mathscr{F}$ and $\mathsf{R}f_*$, it would also be false for $\mathscr{F}$ and $\mathsf{R}b_*\mathsf{R}f_* = \mathsf{R}a_*$: a contradiction.

Corollary 1.5. *Under the hypotheses of the theorem, the categories* $\mathsf{D}_c(X, A)$ *and* $\mathsf{D}_c(Y, A)$ *are taken into one another by the* 4 *operations* $\mathsf{R}f_*$, $\mathsf{R}f_!$, f^*, $\mathsf{R}f^!$.

The case of $\mathsf{R}f_*$ is treated above, that of $\mathsf{R}f_!$ in [2, XVII 5.3], and that of f^* is clear. It remains to consider $\mathsf{R}f^!$. The problem is local, which makes it possible to suppose that f factors as $X \xrightarrow{i} Z \xrightarrow{g} Y$ (i a closed immersion and g smooth, purely of relative dimension n). Poincaré duality $\mathsf{R}g_!K(n)[2n]$ and the transitivity $\mathsf{R}f^! = \mathsf{R}i^!\mathsf{R}g^!$ reduce us to proving 1.5 for i. For every $L \in \mathsf{D}(Z, A)$, if j is the inclusion into Z of $U = Z \smallsetminus X$, then $i_*\mathsf{R}i^!L$ is the mapping cylinder of $K \to \mathsf{R}j_*j^*K$, and 1.5 for i follows from 1.1 for j.

Corollary 1.6. *Let* X *be as in the theorem, and suppose that* A *is commutative. Then, if* $\mathscr{F}$ *and* $\mathscr{G}$ *are constructible sheaves of* A*-modules on* X*, the* $\mathscr{E}xt^i_A(\mathscr{F}, \mathscr{G})$ *are constructible:* $\mathsf{R}\mathscr{H}om$ *sends* $\mathsf{D}^-_c(X, A) \times \mathsf{D}^+_c(X, A)$ *into* $\mathsf{D}^+_c(X, A)$.

By dévissage of $\mathscr{F}$, we reduce to assuming that $\mathscr{F}$ has the form $j_!\mathscr{F}_1$ ($j : Y \hookrightarrow X$ a locally closed immersion and $\mathscr{F}_1$ locally constant on Y). One then has

$$\mathsf{R}\mathscr{H}om(j_!\mathscr{F}_1, \mathscr{G}) = \mathsf{R}j_*\,\mathscr{H}om(\mathscr{F}_1, \mathsf{R}j^!\mathscr{G}):$$

by 1.3, we are reduced to the case where $\mathscr{F}$ is locally constant—or even constant, since the problem is local. For $\mathscr{F}$ locally constant and constructible, one has $\mathscr{H}om(\mathscr{F}, \mathscr{G})_x = \hom(\mathscr{F}_x, \mathscr{G}_x)$, and likewise for $\mathsf{R}\mathscr{H}om$. For $\mathscr{F}$ constant, the $\mathscr{E}xt^i$ can therefore be calculated using a projective resolution of finite type of its constant value, and the $\mathscr{E}xt^i$ are constructible if $\mathscr{G}$ is—whence the corollary.

1.7 Remark

Since $\mathsf{R}f_*$ has finite cohomological dimension, it takes complexes of finite tor-dimension (resp. $\leqslant d$) to complexes of finite tor-dimension (resp. $\leqslant d$) [2, XVII 5.2.11]. [2, XVII 5.2.10] and the proof of 1.5 then show that finite tor-dimension is stable under the 4 operations $\mathsf{R}f_*$, $\mathsf{R}f_!$, f^*, $\mathsf{R}f^!$. A variant of the argument of 1.6 (apply dévissage to K along a partition of x so that the cohomology sheaves become locally constant, then localize so as to replace K by a finite complex of locally free sheaves of finite type) then shows that, for A commutative, $\mathsf{R}\mathscr{H}om$ induces

$$\mathsf{R}\mathscr{H}om : \mathsf{D}^b_{\mathrm{ctf}}(X, A) \times \mathsf{D}^b_{\mathrm{tf}}(X, A) \to \mathsf{D}^+_{\mathrm{tf}}(X, A)$$

(t.f.: finite tor-dimension).

1.8

Under the hypotheses of the theorem, the same method allows us to prove a local biduality theorem $K \xrightarrow{\sim} DDK$ (Section 4). We also prove a finiteness theorem for vanishing-cycle sheaves. For arbitrary S, one still obtains a "generic" theorem:

Theorem 1.9. *Let $f : X \to Y$ be a morphism of S-schemes of finite type, and let $\mathscr{F}$ be a constructible sheaf of A-modules on X. There is a dense open subset U of S such that*

(i) Above U, the $\mathsf{R}^i f_* \mathscr{F}$ are constructible, and all but finitely many of them vanish.

(ii) Formation of the $\mathsf{R}^i f_* \mathscr{F}$ is compatible with every base change $S' \to U \subset S$.

For S the spectrum of a field, one has $U = S$.

If S is the spectrum of a field, a passage-to-the-limit argument gives compatibility with S-base changes for the $\mathsf{R}^i f_*$ for every quasi-compact quasi-separated morphism of S-schemes and every sheaf $\mathscr{F}$.

Corollary 1.10. *Let x be a scheme of finite type over a separably closed k, and let $\mathscr{F}$ be a constructible sheaf of A-modules. Then the $\mathrm{H}^i(X, \mathscr{F})$ are of finite type.*

This is the special case $S = \mathrm{Spec}(k)$, $Y = S$.

Corollary 1.11. *Let X and Y be two schemes of finite type over a separably closed k, and let $K \in \mathrm{Ob}\, \mathsf{D}^-(X, A^\circ)$, $L \in \mathrm{Ob}\, \mathsf{D}^-(Y, A)$ be complexes of sheaves of right and left modules. The Künneth arrow*

$$\mathsf{R}\Gamma(X, K) \overset{\mathsf{L}}{\otimes} \mathsf{R}\Gamma(Y, L) \to \mathsf{R}\Gamma(X \times Y, \mathrm{pr}_1^* K \overset{\mathsf{L}}{\otimes} \mathrm{pr}_2^* L)$$

is an isomorphism.

Proceed as in [2, XVII 5.4.3]:

$$\begin{array}{ccc} X \times Y & \xrightarrow{\mathrm{pr}_1} & X \\ \downarrow{\scriptstyle \mathrm{pr}_2} & & \downarrow{\scriptstyle a} \\ Y & \xrightarrow{b} & \mathrm{Spec}(k) \end{array}$$

base change by b shows that $\mathsf{R}\mathrm{pr}_{2,*}\mathrm{pr}_1^* K$ is $b^* \mathsf{R}\Gamma(X, K)$. One then has (cf. [2, XVII 5.2.11] and the proof)

$$\begin{aligned} \mathsf{R}\Gamma(X \times Y, \mathrm{pr}_1^* K \overset{\mathsf{L}}{\otimes} \mathrm{pr}_2^* L) &= \mathsf{R}\Gamma(Y, \mathsf{R}\mathrm{pr}_{2,*}(\mathrm{pr}_1^* K \overset{\mathsf{L}}{\otimes} \mathrm{pr}_2^* L)) \\ &= \mathsf{R}\Gamma(Y, (\mathsf{R}\mathrm{pr}_{2,*}\mathrm{pr}_1^* K) \overset{\mathsf{L}}{\otimes} L) \\ &= \mathsf{R}\Gamma(Y, b^* \mathsf{R}\Gamma(X, K) \overset{\mathsf{L}}{\otimes} L) \\ &= \mathsf{R}\Gamma(X, K) \overset{\mathsf{L}}{\otimes} \mathsf{R}\Gamma(Y, L) \end{aligned}$$

1.12

Finally, as a local counterpart of 1.9(ii), we shall prove a generic local acyclicity theorem (2.13).

2 Generic theorems

In this section, we prove 1.9 and the generic local acyclicity theorem 2.13. To prove 1.9, we immediately reduce to the case where S is integral. Let η be its generic point.

2.1

We begin by proving 1.9 under the following additional assumptions: X is smooth over S, purely of relative dimension n, $A = \mathbb{Z}/m$, $\mathscr{F}$ is locally constant, and $Y = S$. Let $\mathscr{F}' = \mathscr{H}om(\mathscr{F}, \mathbb{Z}/m)$. We shall show that if the $\mathsf{R}^i f_! \mathscr{F}'$ are locally constant, the conclusions of 1.9 hold with $U = S$. Recall that if $\mathscr{L}$ is a constructible locally constant sheaf, the $\mathscr{E}xt^i(\mathscr{L}, \mathscr{G})$ may be computed fiber by fiber, and are constructible if $\mathscr{G}$ is. Recall also that $\mathbb{Z}/m$ is an injective $\mathbb{Z}/m$-module and is the dualizing module, so that $\mathscr{F} = \mathsf{R}\mathscr{H}om(\mathscr{F}', \mathbb{Z}/m)$. Poincaré duality

$$\mathsf{R}f_* \, \mathsf{R}\mathscr{H}om(K, \mathsf{R}f^! L) = \mathsf{R}\mathscr{H}om(\mathsf{R}f_! K, L),$$

for $K = \mathscr{F}'$, $L = \mathbb{Z}/m$, $\mathsf{R}f^! L = \mathbb{Z}/m[2n](n)$, therefore gives

$$\mathsf{R}^{2n-i} f_* \mathscr{F} = \mathscr{H}om(\mathsf{R}^i f_! \mathscr{F}', \mathbb{Z}/m)(-n).$$

The sheaf on the right is locally constant and its formation commutes with every base change, which proves the assertion.

2.2

Let us prove 1.9 under the additional assumptions that X is smooth over S, $\mathscr{F}$ is locally constant, and $Y = S$.

a) By decomposing X into connected components, we reduce to the case where it is purely of some relative dimension n over S.

b) By decomposing A as a product, we reduce to the case where $\ell^m A = 0$, with ℓ a prime invertible on S; we then filter $\mathscr{F}$ by the $\ell^k \mathscr{F}$ and use the corresponding spectral sequence to reduce to the case $\ell \mathscr{F} = 0$. We may then replace A by $A/\ell A$ and assume that $\ell A = 0$.

c) After replacing S by a suitable U, we may assume that there exists a finite étale Galois covering X_1/X, with Galois group G, such that the inverse image $\mathscr{F}_1$ of $\mathscr{F}$ on X_1 is a constant sheaf, with constant value F. Writing f_1 for the projection of X_1 onto S, we then have

$$\mathsf{R}^i f_{1*} \mathscr{F}_1 = (\mathsf{R}^i f_{1*} \mathbb{Z}/\ell) \otimes_{\mathbb{Z}/\ell} F.$$

We also have the Hochschild–Serre spectral sequence (or the Leray spectral sequence for the covering X_1/X)

$$\underline{\mathrm{H}}^p(G, \mathsf{R}^q f_{1*} \mathscr{F}_1) \Rightarrow \mathsf{R}^{p+q} f_* \mathscr{F}.$$

By 2.1, after shrinking U if necessary, we may assume that the $\mathsf{R}^i f_{1*} \mathbb{Z}/\ell$ are locally constant and that their formation commutes with every base change. The same property then holds for the $\mathsf{R}^i f_* \mathscr{F}$. Finally, if $\bar{\eta}$ is a geometric point localized at the generic point η of S, almost all the $\mathsf{R}^i f_* \mathscr{F}$ vanish, because the $(\mathsf{R}^i f_* \mathscr{F})_{\bar{\eta}} = \mathrm{H}^i(X_{\bar{\eta}}, \mathscr{F})$ do.

2.3

We prove by induction on n that

$$\begin{array}{c} \text{The conclusions of 1.9 hold when } \dim X_\eta \leqslant n \\ \text{and } f \text{ is an open immersion with dense image.} \end{array} \qquad (*_n)$$

For $n = 0$, after shrinking S if necessary, we have $X = Y$: $(*_0)$ is clear. Assume $(*_{n-1})$, and prove $(*_n)$. In $(*_{n-1})$, "open immersion" may be replaced by "immersion," as is seen by factoring it as an open immersion followed by a closed immersion.

Lemma 2.4. *After shrinking S if necessary, the conclusions of 1.9 hold over $Y' \subset Y$, where the complement Y_1 of Y' is finite over S.*

The assertion is local on Y, which we may assume affine: $Y \subset \mathbb{A}^n_S$. The induction hypothesis $(*_{n-1})$ applies to

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & \searrow & \downarrow \mathrm{pr}_i \\ & & \mathbb{A}^1_S \end{array}$$

Thus, for each i, there exists a dense open subset U_i of $\mathbb{A}^1_S$ such that the conclusions of 1.9 hold over $\mathrm{pr}_i^{-1}(U_i)$; they hold over the union of the $\mathrm{pr}_i^{-1}(U_i)$, and 2.4 follows.

2.6

Let us prove $(*_n)$ when X is smooth over S and $\mathscr{F}$ is locally constant on X. Since the problem is local on Y, we may first assume Y affine and then projective (replacing Y by its closure in a projective space). Let $i : Y_1 \hookrightarrow Y$ and $j : Y' \to Y$ be as in 2.4.

$$\begin{array}{ccccc} X & \hookrightarrow & Y & \xleftarrow{i} & Y_1 \\ & \searrow^{a} & \downarrow{\scriptstyle b} & \swarrow_{b_1} & \\ & & S & & \end{array}$$

After shrinking S if necessary, we know that $j^*\mathsf{R}f_*\mathscr{F}$ is constructible and that its formation commutes with every base change in S; we also know that $\mathsf{R}a_*\mathscr{F} = \mathsf{R}b_*\mathsf{R}f_*\mathscr{F}$ is constructible and that its formation commutes with every base change.

Apply $\mathsf{R}b_*$ to the triangle defined by the exact sequence

$$0 \longrightarrow j_!j^*\mathsf{R}f_*\mathscr{F} \longrightarrow \mathsf{R}f_*\mathscr{F} \longrightarrow i_!i^*\mathsf{R}f_*\mathscr{F} \longrightarrow 0: \tag{1}$$

we obtain a triangle

$$\longrightarrow \mathsf{R}b_*j_!j^*\mathsf{R}f_*\mathscr{F} \longrightarrow \mathsf{R}a_*\mathscr{F} \longrightarrow b_{1*}i^*\mathsf{R}f_*\mathscr{F} \longrightarrow \tag{2}$$

in which the first two terms are constructible and their formation commutes with every base change in S (for the first, by the finiteness theorem for the proper morphism b). The same therefore holds for the third. Since b_1 is finite, it follows that $i^*\mathsf{R}f_*\mathscr{F}$ is constructible and its formation commutes with every base change in S; the same holds for $\mathsf{R}f_*\mathscr{F}$ by (1).

2.7

Let us prove $(*_n)$ in general. We first reduce to the case where X contains a dense open subset V smooth over S. When S is the spectrum of a perfect field, it is enough to replace X by X_{red} (and Y by Y_{red}). In general, we must shrink S, make a finite, radicial, surjective base change $S' \to S$, and replace X and Y by X_{red} and Y_{red}. Since the étale topology is insensitive to finite, radicial, surjective morphisms, this is harmless. After shrinking V, we may assume that $\mathscr{F}$ is locally constant on V.

$$V \xhookrightarrow{i} X \xhookrightarrow{f} Y.$$

Define Δ by the triangle

$$\longrightarrow \mathscr{F} \longrightarrow \mathsf{R}j_*j^*\mathscr{F} \longrightarrow \Delta \longrightarrow . \tag{1}$$

The cohomology sheaves of Δ are supported on $X \smallsetminus V$, and $\dim(X \smallsetminus V)_\eta < n$. The induction hypothesis therefore allows us to assume that $\mathsf{R}f_*\Delta$ is constructible. Applying $\mathsf{R}f_*$ to the triangle (1), we obtain a triangle

$$\longrightarrow \mathsf{R}f_*\mathscr{F} \longrightarrow \mathsf{R}(fj)_*j^*\mathscr{F} \longrightarrow \mathsf{R}f_*\Delta \longrightarrow$$

in which two of the vertices are constructible and their formation commutes with every base change in S. The same therefore holds for the third.

2.8

Let us prove 1.9. The problem is local on Y, which we may assume affine. Taking an affine covering of X and invoking the Leray spectral sequence, we reduce to the case where X is affine as well. This ensures that we can factor f as an open immersion followed by a proper morphism: $f = gj$, hence $\mathsf{R}f_* = \mathsf{R}g_*\mathsf{R}j_*$. The open immersion is covered by $(*_n)$, and the proper morphism by the finiteness theorem.

The following corollaries are proved as in Section 1.

Corollary 2.9. *Under the hypotheses of the theorem, for K in $\mathsf{D}^b_c(X, A)$ or $\mathsf{D}^b_c(Y, A)$ respectively, there exists a nonempty open subset U of S over which $\mathsf{R}f_*K$, $\mathsf{R}f_!K$, f^*K, and $\mathsf{R}f^!K$ belong to $\mathsf{D}^b_c(Y, A)$ or $\mathsf{D}^b_c(X, A)$, and their formation commutes with every base change $S' \to U \subset S$.*

Corollary 2.10. *Let X be as in the theorem, and suppose that A is commutative. Then, if $\mathscr{F}$ and $\mathscr{G}$ are constructible sheaves of A-modules on X, over a dense open subset U of S, the $\mathscr{E}x\ell^i_A(\mathscr{F}, \mathscr{G})$ are again constructible and their formation commutes with every base change $S' \to U \subset S$.*

2.11

If x is a geometric point of a scheme X, we denote by X_x the strict henselization of X at x. For $f : X \to S$ and t a geometric point of S, we denote by X_t the geometric fiber of X at t. Finally, for x a geometric point of X and t a geometric point of $S_{f(x)}$, $(X_x)_t$ is the fiber at t of $X_x \to S_{f(x)}$.

Definition 2.12. *Let $f : X \to S$ and $K \in \mathrm{Ob}\,\mathsf{D}^+(X, A)$. We say that f is* locally acyclic at x relative to *K if, for every geometric point t of $S_{f(x)}$, we have $K_x = \mathsf{R}\Gamma(X_x, K) \xrightarrow{\sim} \mathsf{R}\Gamma(X_{x,t}, K)$. We say that f is* locally acyclic relative to *K if this holds for every x, and* universally locally acyclic relative to *K if it remains true after every base change $S' \to S$.*

Theorem 2.13. *Let $f : X \to S$ be a morphism of finite type and let $\mathscr{F}$ be constructible on X. There exists a dense open subset U of S over which f is universally locally acyclic relative to $\mathscr{F}$.*

We shall use the following result, proved in the appendix.

Lemma 2.14. *Let $X \xrightarrow{f} S_1 \xrightarrow{g} S_2$. If g is smooth and f is universally locally acyclic relative to K, then so is gf.*

We reduce to the case where S is integral, with generic point η, and argue by induction on $\dim X_\eta$. We first deduce from the induction hypothesis that

$$\text{After shrinking } S, \text{ there exists } T \subset X, \text{ finite over } S, \text{ such that } f \text{ is universally locally acyclic outside } T. \tag{A}$$

Since this question is local, we localize on X and factor f as $X \xrightarrow{u} \mathbb{A}^1_S \xrightarrow{S}$. The induction hypothesis applies to u, and we conclude by 2.14 and the usual arguments.

To prove the theorem, we may assume that X is proper, since the problem is local. We shrink S so that the $\mathsf{R}^i f_* \mathscr{F}$ are locally constant and (A) applies, and use the following lemma.

Lemma 2.15. *Let $f : X \to S$ be proper and let $\mathscr{F}$ be constructible. Suppose that the $\mathsf{R}^i f_* \mathscr{F}$ are locally constant and that, outside $T \subset X$ finite over S, f is locally acyclic relative to $\mathscr{F}$. Then f is locally acyclic relative to $\mathscr{F}$.*

Let s be a geometric point of S, let S_s be the strict localization of S at s, and let t be a geometric point of S_s. Let $X_{(s)}$ be the inverse image of X on S_s, let $\bar{j} : X_t \to X_{(s)}$, and let $i : X_s \hookrightarrow X_{(s)}$. Again denoting by $\mathscr{F}$ the inverse image of $\mathscr{F}$ on $X_{(s)}$ or X_t, we must prove that $i^*\mathscr{F} \xrightarrow{\sim} i^*\mathsf{R}\bar{j}_*\mathscr{F}$. Let Δ be the mapping cylinder of this map. Its cohomology sheaves are supported on T_s. To prove that $\Delta = 0$, it therefore suffices to prove that $\mathsf{R}\Gamma(X_s, \Delta) = 0$. This is the mapping cylinder of $(\mathsf{R}f_*\mathscr{F})_s = \mathsf{R}\Gamma(X_s, \mathscr{F}) \to \mathsf{R}\Gamma(X_s, i^*\mathsf{R}\bar{j}_*\mathscr{F}) = \mathsf{R}\Gamma(X_{(s)}, \mathsf{R}\bar{j}_*\mathscr{F}) = \mathsf{R}\Gamma(X_t, \mathscr{F}) = (\mathsf{R}f_*\mathscr{F})_t$. By hypothesis this specialization morphism is an isomorphism, and $\Delta = 0$.

Corollary 2.16. *When S is the spectrum of a field, every S-scheme X is universally locally acyclic relative to K, for every $K \in \operatorname{Ob} \mathsf{D}^+(X, A)$.*

This follows from 2.13 by passage to the limit (which is possible because the U of 2.13 is always equal to S.

3 Proof of 1.1 and constructibility of the vanishing-cycle sheaves

3.1

Let S be a strictly local trait (the spectrum of a henselian discrete valuation ring with separably closed residue field). Denote its closed and generic points by s and η, and let $\bar{\eta}$ be a geometric point localized at η (a separable closure of $k(\eta)$). Let X be over S and let $\mathscr{F}$ be a sheaf on X_η. Recall the definition of the vanishing-cycle sheaves $\mathsf{R}^i\Psi_\eta(\mathscr{F})$ (sheaves on X_s, endowed with an action of $\mathrm{Gal}(\bar{\eta}/\eta)$). Let $i : X_s \hookrightarrow X$, $j : X_\eta \hookrightarrow X$, and let $\bar{j}$ be the composite $X_{\bar{\eta}} \to X_\eta \hookrightarrow X$; then

$$\mathsf{R}^i\Psi_\eta(\mathscr{F}) = i^*\mathsf{R}^i\bar{j}_*(\bar{j}^*\mathscr{F}).$$

Here is the main theorem of this subsection. It improves [16, XIII 2.3.1, 2.4.2].

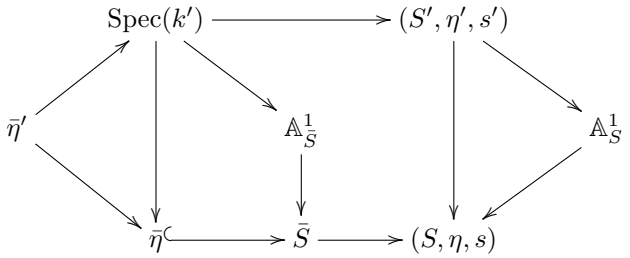
Theorem 3.2. *Suppose that X is of finite type over S and that $\mathscr{F}$ is constructible. Then the vanishing-cycle sheaves $\mathsf{R}^i\Psi_\eta(\mathscr{F})$ are constructible.*

We argue by induction on the dimension n of X_η. We may moreover assume—and do assume—that X_η is dense in X (replacing X by $\bar{X}_\eta$ does not change the $\mathsf{R}^i\Psi$, which are supported on $\bar{X}_\eta$).

Lemma 3.3. *If 3.2 holds when $X_\eta < n$, and if $\dim X_\eta = n$, then there exist constructible subsheaves $\mathscr{G}_i$ of the $\mathsf{R}^i\Psi_\eta(\mathscr{F})$ such that the supports of the local sections of $\mathsf{R}^i\Psi_\eta(\mathscr{F})/\mathscr{G}$ are finite.*

Let s' be a geometric generic point of the affine line over s, and let S' be the strict localization at s' of

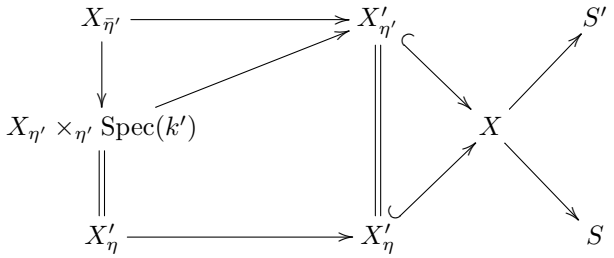
the affine line $\mathbb{A}^1_S$ over S. It is again a strictly local trait, and uniformizers for S are uniformizers on S'.



Let $k' = k(\bar\eta) \otimes_{k(\eta)} k(\eta')$. If $\bar S$ is the normalization of S in $\bar\eta$, then k' is the fraction field of the strict localization of $\mathbb{A}^1_{\bar S}$ at s'; it is therefore a field, and $\mathrm{Gal}(\bar\eta/\eta) = \mathrm{Gal}(k'/\eta')$. Let $\bar\eta'$ be the spectrum of an algebraic closure of k'. The Galois group $P = \mathrm{Gal}(\bar\eta'/k')$ is a pro-p group, where p is the characteristic exponent of $k(s)$.

Lemma 3.4. *For every scheme X' over S', and every sheaf $\mathscr{F}$ on $X'_\eta = X'_{\eta'}$, the vanishing-cycle sheaves for X'/S' and for X'/S are related by $\mathsf{R}^i\Psi_\eta(\mathscr{F}) = \mathsf{R}^i\Psi_{\eta'}(\mathscr{F})^P$.*

The following diagram compares the morphisms used in the definition of $\mathsf{R}\Psi$ for X'/S' and X'/S:



and the lemma follows from the Hochschild–Serre spectral sequence, since P is a pro-p group and p is invertible in A.

Let us prove 3.3. The question is local; this allows us to assume that X is affine, $X \subset \mathbb{A}^n_S$. Let f be one of the projections $X \subset \mathbb{A}^n_S \to \mathbb{A}^1_S$. Let X' be the "localization" $X_{\mathbb{A}^1_S} S'$ of x, and let $\mathscr{F}'$ be the inverse image of $\mathscr{F}$ on x'.

$$\begin{array}{ccccc} \mathscr{F}' \text{ on } X' & \longrightarrow & S' & & \\ \downarrow{\scriptstyle\lambda} & & \downarrow{\scriptstyle\lambda} & & \\ \mathscr{F} \text{ on } X & \xrightarrow{f} & \mathbb{A}^1_S & \longrightarrow & S. \end{array}$$

On $X'_s = X'_{s'}$, we have

$$\lambda^* \mathsf{R}^i\Psi_\eta(\mathscr{F}) = \mathsf{R}^i\Psi_\eta(\mathscr{F}') = \mathsf{R}^i\Psi_{\eta'}(\mathscr{F}')^P:$$

this sheaf is constructible because the induction hypothesis applies to X'/S', and we use the following lemma, applied to $X_s \subset \mathbb{A}^n_S$ and to the vanishing-cycle sheaves.

Lemma 3.5. *Let $\mathbb{A}^n$ be affine n-space over a field k, let $X \subset \mathbb{A}^n$, let $]sF$ be a sheaf of A-modules on X, and let $\bar\eta$ be a geometric generic point of $\mathbb{A}^1$. Let $X_{\bar\eta,i}$ be the geometric generic fiber of $X \subset \mathbb{A}^n \xrightarrow{\mathrm{pr}_i} \mathbb{A}^1$, and let $\mathscr{F}_{\bar\eta,i}$ be the restriction of $\mathscr{F}$ to $X_{\bar\eta,i}$. If the $\mathscr{F}_{\bar\eta,i}$ are constructible, there exists a constructible $\mathscr{F}' \subset \mathscr{F}$ such that the local sections of $\mathscr{F}/\mathscr{F}'$ have finite support.*

By passage to the limit, for each i

a) There exists an étale neighborhood U of $\bar{\eta}$ and a constructible sheaf $\mathscr{H}$ on $X_{U,i} = X \times_{\mathbb{A}^1,\mathrm{pr}_i} U$ whose restriction $\mathscr{F}_{\bar{\eta},i}$ to $X_{\bar{\eta},i}$ is the given one.

b) For a suitable U, the isomorphism $\mathscr{H}_{\bar{\eta},i} \xrightarrow{\sim} \mathscr{F}_{\bar{\eta},i}$ comes from $u : \mathscr{H} \to \mathscr{F}_{U,i}$, where $\mathscr{F}_{U,i}$ is the inverse image of $\mathscr{F}$ on $X_{U,i}$. Let $\varphi : X_{U,i} \to X$. The morphism u defines $v_i : \varphi_!\mathscr{H} \to \mathscr{F}$, with image $\mathscr{F}'_i$. We have $(\mathscr{F}/\mathscr{F}'_i)_{\bar{\eta},i} = 0$, and for $\mathscr{F}'$ we take the sum of the $\mathscr{F}'_i$.

3.6

Let us prove 3.2 in dimension n. We may assume that X is affine (because the problem is local on X_s), and then projective over S (by taking the closure of X in a projective embedding). We then have a spectral sequence [16, I 2.2.3] (the Leray spectral sequence for $\bar{j}$, taking into account the base-change theorem for the proper morphism $X \to S$).

$$E_2^{pq} = \mathrm{H}^p(X_s, \mathsf{R}^i\Psi_\eta(\mathscr{F})) \Rightarrow \mathrm{H}^{p+q}(X_{\bar{\eta}}, \mathscr{F}). \tag{1}$$

Let $\mathscr{G}^q \subset \mathsf{R}^q\Psi_\eta(\mathscr{F})$ be as in 3.3, and let $\mathscr{H}^q$ be the quotient sheaf. We have $\mathrm{H}^i(X_s, \mathscr{H}^q) = 0$ for $i \neq 0$, and for $\mathscr{H}^q$, hence $\mathsf{R}^q\Psi_\eta(\mathscr{F})$, to be constructible, it suffices that $\mathrm{H}^0(X_s, \mathscr{H}^q)$ be of finite type.

Compute (1) modulo modules of finite type (i.e. in the quotient of the category of A-modules by the thick subcategory of A-modules of finite type). The long cohomology exact sequence deduced from $0 \to \mathscr{G}^q \to \mathsf{R}^q\Psi_\eta(\mathscr{F}) \to \mathscr{H}^q \to 0$, together with 1.10 applied to $\mathscr{G}^q$, gives $E_2^{pq} \sim \mathrm{H}^q(X_s, \mathscr{H}^q)$. In particular, $E_2^{pq} \sim 0$ for $p \neq 0$, $E_2^{0q} \sim \mathrm{H}^q(X_{\bar{\eta}}, \mathscr{F}) \sim 0$, and this completes the proof.

Parallel arguments give the following result, which improves [16, XIII 2.1.12, 2.4.2].

Proposition 3.7. *The formation of the vanishing-cycle sheaves commutes with changes of traits.*

Let $g : (S', \eta', s') \to (S, \eta, s)$ be a (surjective) morphism of strictly local traits, let X/S, let $\mathscr{F}$ be on X_η, of torsion prime to the residual characteristic, and let $(X', \mathscr{F}')$ be their inverse images on S'. Again denoting by g the morphisms parallel to g, such as $X'_{s'} \to X_s$, we must prove that

$$g^*\mathsf{R}\Psi_\eta(\mathscr{F}) \xrightarrow{\sim} \mathsf{R}\Psi_{\eta'}(\mathscr{F}'). \tag{3.7.1}$$

This morphism is defined by the commutative diagram

$$\begin{array}{ccccc} X'_{s'} & \xrightarrow{i'} & X' & \xleftarrow{\bar{j}'} & X'_{\eta'} \\ \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle g} \\ X_s & \xrightarrow{i} & X & \xleftarrow{\bar{j}} & X_{\bar{\eta}} \end{array}$$

A passage to the limit reduces us to the case where X is of finite type over S, and we argue by induction on $\dim X_\eta$. Since the question is local, we may assume that X is affine, and then projective. Assume (3.7.1) when $\dim X_\eta < n$. When $\dim X_\eta = n$, it then follows from the following two assertions, where Δ is the mapping cylinder of (3.7.1).

(A) The support of the local sections of the cohomology sheaves of Δ is finite.

(B) $\mathsf{R}\Gamma(X_s, \Delta) = 0$, hence $\Delta = 0$, by (A).

3.8

The proof of (A) parallels that of 3.3. We localize on X and consider maps $X \to \mathbb{A}^1_S$; denoting by $S(x)$ the strict henselization of $\mathbb{A}^1_S$ at the generic point of the special fiber, we apply the induction hypothesis to $X_1/S(x)$ ($X_1 = X \times_{\mathbb{A}^1} S(x)$) and to $S'(x)$. Taking invariants under a pro-p group, we find that Δ vanishes on the geometric generic fiber of $X_{s'} \to \mathbb{A}^1_s$. Since this holds locally on X and for every projection, we obtain (A).

3.9

For (B), the properness of X over S ensures that

$$\mathsf{R}\Gamma(X'_{s'}, \mathsf{R}\Psi_{\eta'}(\mathscr{F}')) = \mathsf{R}\Gamma(X'_{\bar{\eta}}, \mathscr{F}')$$

and

$$\mathsf{R}\Gamma(X_s, \mathsf{R}\Psi_{\eta}(\mathscr{F})) = \mathsf{R}\Gamma(X_{\bar{\eta}}, \mathscr{F}).$$

We have $\mathsf{R}\Gamma(X_s, \mathsf{R}\Psi_\eta(\mathscr{F})) \xrightarrow{\sim} \mathsf{R}\Gamma(X'_{s'}, g^*\mathsf{R}\Psi_\eta(\mathscr{F}))$ (invariance under change of the separably closed base field); thus $\mathsf{R}\Gamma(X'_{s'}, \Delta)$ is the mapping cylinder of $\mathsf{R}\Gamma(X_{\bar{\eta}}, \mathscr{F}) \to \mathsf{R}\Gamma(X'_{\bar{\eta}}, \mathscr{F}')$, an isomorphism by the same invariance theorem.

3.10

Let us prove 1.1. We reduce to the case where S is connected, hence integral. If $\dim S = 0$ (S is the spectrum of a field), apply 1.9, 1.10. If S has dimension 1, Theorem 1.9 ensures that the $\mathsf{R}^i f_* \mathscr{F}$ are constructible over the complement of a finite set T of points of S. It remains to see that their restrictions to the Y_t ($t \in T$) are constructible. It suffices to see this after localization at t: we may assume that S is a strictly local trait. The essential case is the following.

Lemma 3.11. *Let X be of finite type over S, let $j : X_\eta \hookrightarrow X$, $i : X_s \hookrightarrow X$, and let $\mathscr{F}$ be constructible on X_η. Then $i^*\mathsf{R}j_*\mathscr{F}$ is constructible.*

Let $I = \mathrm{Gal}(\bar{\eta}/\eta)$ be the inertia group. It is known to be an extension of $\widehat{\mathbb{Z}}_{p'}(1)$ by a pro-p group P (p being the characteristic exponent of the residue field). The Hochschild–Serre spectral sequence gives

$$E_2^{pq} = \mathscr{H}^p(I, \mathsf{R}^q\Psi_\eta(\mathscr{F})) \Rightarrow i^*\mathsf{R}^{p+q}j_*\mathscr{F}.$$

Let $R^q_t = \mathsf{R}^q\Psi_\eta(\mathscr{F})^P$ (t for tame). If σ is a generator of $\widehat{\mathbb{Z}}_{p'}(1)$, then $E_2^{0q} = \ker(\sigma - 1, R^q_t)$, $E_2^{1q} = \mathrm{coker}(\sigma - 1, R^q_t)$, and $E_2^{pq} = 0$ for $p \neq 0, 1$. These sheaves are constructible because the vanishing-cycle sheaves are, and 3.11 follows.

3.12

Let us treat the general case, with S still a strictly henselian trait. If $X = X_\eta$, then f is the composite $X \to Y_\eta \to Y$, and we apply 1.9 and 3.11. In the general case, let $j : X_\eta \hookrightarrow X$ and let Δ be the mapping cylinder of $\mathscr{F} \to \mathsf{R}j_*j^*\mathscr{F}$. Its cohomology sheaves are supported on X_s; by 1.9 applied to $X_s \to Y_{s'}$, $\mathsf{R}f_*\Delta$ is therefore constructible. The complex $\mathsf{R}f_*\mathsf{R}j_*j^*\mathscr{F} = \mathsf{R}(fj)_*j^*\mathscr{F}$ is also constructible, and we conclude from the triangle

$$\longrightarrow \mathsf{R}f_*\mathscr{F} \longrightarrow \mathsf{R}f_*\mathsf{R}j_*j^*\mathscr{F} \longrightarrow \mathsf{R}f_*\Delta \longrightarrow .$$

4 Local biduality

4.1

Let S be regular of dimension 0 or 1, and put $K_S = A$ (the constant sheaf with value A). For $K \in \mathrm{Ob}\,\mathsf{D}^b_{\mathrm{ctf}}(S, A)$, put $DK = \mathsf{R}\mathscr{H}om(K, K_S) \in \mathrm{Ob}\,\mathsf{D}^+(S, A^\circ)$ (a complex of sheaves of right A-modules). We still have $DK \in \mathrm{Ob}\,\mathsf{D}^b_{\mathrm{ctf}}(S, A^0)$, and an explicit calculation, possible because S has dimension 1, shows that $K \xrightarrow{\sim} DDK$ (for $A = \mathbb{Z}/n$, Duality 1.4).

4.2

We assume that A is commutative, an assumption that is probably unnecessary. For $a : X \to S$ of finite type over S, put $K_X = \mathsf{R}a^! K_S$. For $K \in \mathrm{Ob}\,\mathsf{D}^b_{\mathrm{ctf}}(S, A)$, put $DK = \mathsf{R}\mathscr{H}om(K, K_X) \in \mathrm{Ob}\,\mathsf{D}^b_{\mathrm{ctf}}(X, A)$. Our main result is the following.

Theorem 4.3. *We have $K \xrightarrow{\sim} DDK$ ($K \in \mathrm{Ob}\,\mathsf{D}^b_{\mathrm{ctf}}(X, A)$).*

Lemma 4.4. *If a is proper, then $\mathsf{R}a_* K \xrightarrow{\sim} \mathsf{R}a_* DDK$.*

Poincaré duality

$$\mathsf{R}a_! \, \mathsf{R}\mathscr{H}om(K, \mathsf{R}a^! K_S) = \mathsf{R}\mathscr{H}om(\mathsf{R}a_! K, K_S)$$

gives us an isomorphism $\mathsf{R}a_* D = D\mathsf{R}a_! = D\mathsf{R}a_*$. The lemma follows from the commutativity of the diagram (Duality, 1.2)

$$\begin{array}{ccc} \mathsf{R}a_* K & \longrightarrow & \mathsf{R}a_* DDK \\ \downarrow \wr & & \downarrow \wr \\ DD\mathsf{R}a_* K & \xrightarrow{\sim} & D\mathsf{R}a_* DK. \end{array}$$

4.5

By localization, it is enough to treat the cases where S is the spectrum of a field or a trait. When S is the spectrum of a field, we argue by induction on $\dim X$. Since the problem is local, we may assume that X is proper. Moreover, the induction hypothesis, by the usual arguments, ensures that the mapping cylinder Δ of $K \to DDK$ has skyscraper cohomology sheaves. The lemma then ensures that $\mathsf{R}a_* \Delta = 0$, hence that $\Delta = 0$.

4.6

When S is a trait, we already know that 4.3 holds on the generic fiber (4.5). We may also assume that X is proper over S, and we argue by induction on $\dim X_s$, with X proper over S. The mapping cylinder δ again has skyscraper cohomology sheaves on X_s, and we conclude as above.

4.7

Suppose that $A = \mathbb{Z}/m$. We then have a variant of the preceding theory in which K is arbitrary in $\mathsf{D}^b_c(X, A)$. The complex $\mathsf{R}a^! \mathbb{Z}/m$ has finite injective dimension [2, XVIII 3.1.7]. This ensures that DK still belongs to $\mathsf{D}^b_c(X, A)$. To prove local biduality over S, we use the fact that $\mathbb{Z}/m$ is the dualizing $\mathbb{Z}/m$-module. We then proceed as above.

5 Appendix, by L. Illusie

In this appendix, which takes up certain parts of the late [21, II], and a letter from P. Deligne to the author, we prove 2.14, as well as various generalizations and variants of the specialization theorems [2, XVI 2.1] and (Étale cohomology 5.1.7).

The schemes and morphisms considered will be assumed quasi-compact and quasi-separated. If X is a scheme and x a geometric point of X, we denote by $X(x)$ the strict localization of X at x.

Fix a base scheme S and a sheaf of rings A on S (not necessarily commutative or noetherian). If X is an S-scheme, we write $\mathsf{D}(X)$ for $\mathsf{D}(X, A_X)$.

5.1 Cohomological properness

Proposition 5.1.1. *Let $f : X \to Y$ be an S-morphism and let $E \in \mathrm{Ob}\,\mathsf{D}^+(X)$. The following conditions are equivalent:*

(i) The formation of $\mathsf{R}f_*E$ commutes with every finite base change $S' \to S$.

(ii) The formation of $\mathsf{R}f_*E$ commutes with every quasi-finite base change (or inverse limit of quasi-finite morphisms) $S' \to S$.

(iii) For every specialization arrow $i : t \to S(s)$ (Étale cohomology, 5.1.2), if $\widetilde{S}$ denotes the normalization in $k(\bar{t})$ of the integral scheme that is the closure of $i(t)$ in $S(s)$ (by [20, IV, 6.15.5, 18.6.11, 18.8.16], $\bar{S}$ is therefore local and integral, with closed point radicial over s), if $\bar{f} : \bar{X} \to \bar{Y}$ is the morphism deduced from f by the base change $\bar{S} \to S$, and if $f_s : X_s \to Y_s$ is the fiber of f at s, then the base-change arrow

$$(\mathsf{R}\bar{f}_*(E|\bar{X}))|Y_s \to \mathsf{R}f_{s*}(E|X_s)$$

is an isomorphism.

The equivalence of (i) and (ii) follows from Zariski's Main Theorem, and it is clear that (ii) implies (iii). Let us prove that (iii) implies (ii). For every $S' \to S$ that is an inverse limit of quasi-finite morphisms, and every geometric point s of S', denote by $C(S', s)$ the cone of the base-change arrow

$$(\mathsf{R}f'_*(E|X'))|Y_s \to \mathsf{R}f_{s*}(E|X_s),$$

where $f' : X' \to Y'$ is deduced from f by the base change $S' \to S$, and $f_s : X_s \to Y_s$ is the fiber of f at s. We must prove that, for every (S', s) as above, $C(S', s)$ is acyclic. We shall prove by induction on N that $\mathrm{H}^i\, C(S', s) = 0$ for $i \leqslant N$. By the Main Theorem, passage to the limit, and elimination of radicial morphisms, we may assume that S and S' are strictly local, that S' is integral with closed point s, and that $S' \to S$ is finite. Let t be a geometric generic point of S', and let $\bar{S}$ be the normalization of S' in $k(t)$. Let $\bar{S}_\bullet$ be the simplicial scheme that is the coskeleton of $S' \to S'$ ($\bar{S}_0 = \bar{S}, \ldots \bar{S}_n = (\bar{S}/S')^{n+1}, \ldots$), and let $X_\bullet = X \times_S \bar{S}_\bullet$. Let $g_\bullet : \bar{X}_\bullet \to X'$ be the canonical projection. Put $G|X' = G'$. The bicomplex $g_{\bullet *} g_\bullet^* G'$, whose columns are the $g_{n*} g_n^* G'$, is a resolution of G' [2, VIII 8]. We may therefore represent $C(S', s)$ by a bicomplex whose columns identify with the $C(\bar{S}_n, s)$. By (iii), $C(\bar{S}_0, s) = C(\bar{S}, s)$ is acyclic. On the other hand, for $n > 0$, we have $\mathrm{H}^i(\bar{S}_n, s) = 0$ for $i \leqslant N$ by the induction hypothesis. It follows that $\mathrm{H}^i\, C(S', s) = 0$ for $i \leqslant N + 1$, which completes the proof.

5.1.2 Remark

Let (f, E) satisfy condition (i) of 5.1.1.

a) If $E \in \mathrm{Ob}\,\mathsf{D}^b(X)$ and f_* has finite cohomological dimension, then for every $F \in \mathrm{Ob}\,\mathsf{D}^-(S, A^\circ)$, the canonical arrow

$$\mathsf{R}f_*(E) \overset{\mathsf{L}}{\otimes}_A q^*F \to \mathsf{R}f_*(E \overset{\mathsf{L}}{\otimes}_A p^*F), \qquad (*)$$

where $p : X \to S$ and $q : Y \to S$ are the projections, is an isomorphism. The same conclusion holds with $E \in \mathrm{Ob}\,\mathsf{D}^-(X)$.

Indeed, by dévissage, it is enough to verify the assertion for F of the form $i_!A_{S'}$, with $i : S' \to S$ quasi-finite. By the Main Theorem, we reduce to the case where i is finite, and the conclusion is then equivalent to the commutation of $\mathsf{R}f_*(E)$ with base change by i.

b) Suppose that A is noetherian and constructible. Then, for every constructible $F \in \mathrm{Ob}\,\mathsf{D}^b(S, A^\circ)$ of finite tor-dimension, the arrow $(*)$ above is an isomorphism.

Indeed, by dévissage, we reduce to the case where F is of the form $i_!M$, with $i : S' \to S$ locally closed, A locally constant on S', and M constructible, of finite tor-dimension, and with locally constant cohomology on S'. After base change from S to S', we are thus reduced to the case where F is perfect [5, I], hence finally, by localization and dévissage, to the case $F = A$, for which the conclusion is immediate.

5.1.3

Let $f : X \to Y$ be an S-morphism and let $E \in \mathrm{Ob}\,\mathsf{D}^+(X)$. We say that (f, E) is *cohomologically proper* rel. to S if the formation of $\mathsf{R}f_*E$ commutes with every base change $S' \to S$. Equivalently, after every base change $S' \to S$, the formation of $\mathsf{R}f'_*E'$ (where $f' = f \times_S S'$ and $E' =$ the inverse image of E on $X \times_S S'$) commutes with every finite base change $S'' \to S'$ (cf. [2, XII 6.1]). Here are some examples of cohomological properness (for a study of the analogous notion for sheaves of sets or of noncommutative groups, the reader may consult [23, XIII]).

1. Suppose that A is torsion and f is proper. Then, for every $E \in \mathrm{Ob}\,\mathsf{D}^+(X)$, (f, E) is cohomologically proper rel. to S (proper base-change theorem, [2, XII 5.1]).

2. Suppose that S is finite, that X and Y are of finite type over S, and that A is annihilated by an integer invertible on S. Then, for every $E \in \mathrm{Ob}\,\mathsf{D}^+(X)$, (f, E) is cohomologically proper rel. to S (1.9).

3. Suppose that A is constant, noetherian, and annihilated by an integer n invertible on S, and that $f : X = Y \smallsetminus D \to Y$ is the inclusion of the complement of a divisor D on Y with normal crossings relative to S [23, XIII 2.1]. Let E be a sheaf of A-modules on X satisfying one of the following conditions:

   (i) E is constructible locally constant and tamely ramified along D;

   (ii) E is, locally for the étale topology on Y and on S, the inverse image of a sheaf of A-modules on S.

   Then (f, E) is cohomologically proper rel. to S, and $\mathsf{R}f_*E$ is constructible (compare [23, XIII 2.4]).

Let us sketch the proof in case (i). The question is local near a point y of Y. We may assume that D is a sum of smooth divisors, $D = \sum_{i=1}^m D_i$. By the relative Abhyankar lemma [23, XIII 5.5], near y we may trivialize E by a finite covering $\widetilde{Y} \to Y$ of the form $\widetilde{Y} = Y[T_1, \ldots, T_r]/(T_1^{n_1} - t_1, \ldots, T_r^{n_r} - t_r)$, where the t_i are local equations of the smooth divisors passing through y, and the n_i are integers prime to the char. of $k(y)$. The inverse image $\widetilde{D}$ of D in Y still has normal crossings rel. to S, and if $g : \widetilde{X} = \widetilde{Y} \smallsetminus \widetilde{D} \to X$ is

the projection, g^*E is constant. Since E injects into g_*g^*E and the quotient is tamely ramified, an easy dévissage reduces us to the case where E is constant. Denote the projections by $p : X \to S$, $q : Y \to S$, and, for $1 \leqslant i \leqslant m$, let $f_i : Y \smallsetminus D_i \to D$ be the canonical inclusion. From the relative purity theorem [2, XVI 3.7], one easily deduces by induction on m that, for every locally constant A-module M on S, the canonical arrow

$$\mathsf{R}f_*(\mathbb{Z}/n)\overset{\mathsf{L}}{\otimes}q^*M \to \mathsf{R}f_*(p^*M) \tag{5.1.3.1}$$

is an isomorphism, and that on the other hand we have:

$$\begin{aligned} f_{i*}(\mathbb{Z}/n) &= \mathbb{Z}/n, \\ \mathsf{R}^1 f_{i*}(\mathbb{Z}/n) &= (\mathbb{Z}/n)(-1)_{D_i}, \end{aligned} \tag{5.1.3.2}$$

where a canonical isomorphism is given by the fundamental class $\mathrm{cl}(D_i)$ (Cycle 2.1.4),

$$\begin{aligned} \mathsf{R}^q f_{i*}(\mathbb{Z}/n) &= 0 \text{ for } q > 1, \\ \mathsf{R}f_*(\mathbb{Z}/n) &= \bigotimes_i^{\mathsf{L}} \mathsf{R}f_{i*}(\mathbb{Z}/n) \text{ , i.e.:} \\ \mathsf{R}^1 f_*(\mathbb{Z}/n) &= \bigoplus_{i=1}^{m} (\mathbb{Z}/n)(-1)_{D_i}, \\ \textstyle\bigwedge^{\bullet} \mathsf{R}^1 f_*(\mathbb{Z}/n) &\xrightarrow{\sim} \mathsf{R}^{\bullet} f_*(\mathbb{Z}/n). \end{aligned}$$

The conclusion of 3, in case (i), therefore follows from (5.1.3.1) and (5.1.3.2). In case (ii), by passage to the limit we reduce to the case where $E = p^*M$, with M constructible, and then, by dévissage and base change (using (i)), to the already treated case where M is constant.

It follows from the preceding proof that (5.1.3.1) is an isomorphism for every $M \in \mathrm{Ob}\,\mathsf{D}^+(S)$.

One may compare the formulas (5.1.3.2) with the analogous formulas in integral cohomology when $S = \mathrm{Spec}(\mathbb{C})$ (see, for example, [12, 3.1]), which follow from the fact that, locally for the classical topology, the complement of D has the homotopy type of a torus.

By passage to the limit, one deduces from (5.1.3.2) similar formulas in ℓ-adic cohomology, i.e. with $\mathbb{Z}/n$ replaced by $\mathbb{Z}_\ell$ (ℓ a prime invertible on S). Suppose that $q : Y \to S$ is proper and smooth. It then follows from the Weil conjectures [14, 15] that the Leray spectral sequence

$$E_2^{ij} = \mathsf{R}^i q_* \mathsf{R}^j f_* \mathbb{Z}_\ell \Rightarrow \mathsf{R}^{\bullet} p_* \mathbb{Z}_\ell$$

degenerates at E_3 modulo torsion [11, §6]. The same phenomenon occurs in integral cohomology when $S = \mathrm{Spec}(\mathbb{C})$; see (loc. cit.) and [12, 3.2.13].

5.2 Specialization and cospecialization

Let $f : X \to S$ and $E \in \mathrm{Ob}\,\mathsf{D}^+(X)$.

5.2.1

Suppose that the formation of $\mathsf{R}f_*E$ commutes with every finite base change. For every specialization $u : t \to S(s)$ of geometric points of S, we then define an arrow, called the *specialization arrow*,

$$\mathrm{sp}(u) : \mathsf{R}\Gamma(X_s, E|X_s) \to \mathsf{R}\Gamma(X_t, E|X_t), \tag{5.2.1.1}$$

as follows. Let, as in 5.1.1(iii), $\bar{S}$ be the normalization in $k(t)$ of the closure of $u(t)$ in $S(s)$, and let $\bar{f} : \bar{X} \to \bar{S}$ be the morphism deduced from f by the base change $\bar{S} \to S$. By the immediate implication (i)⇒(iii) of 5.1.1, the base-change arrow

$$\mathsf{R}\Gamma(\bar{X}, E|\bar{X}) = \mathsf{R}\bar{f}_*(E|\bar{X})_s \to \mathsf{R}\Gamma(X_s, E|X_s) \tag{5.2.1.2}$$

is an isomorphism. We define (5.2.1.1) as the composite of the inverse of (5.2.1.2) with the restriction arrow

$$\mathsf{R}\Gamma(\bar{X}, E|\bar{X}) \to \mathsf{R}\Gamma(X_t, E|X_t). \tag{5.2.1.3}$$

5.2.2

Suppose that f is locally acyclic rel. to E (2.12). For every specialization $u : t \to S(s)$ of geometric points of S, we then define an arrow, called the *cospecialization arrow*,

$$\mathrm{cosp}(u) : \mathsf{R}\Gamma(X_t, E|X_t) \to \mathsf{R}\Gamma(X_s, E|X_s), \tag{5.2.2.1}$$

as follows. Let $g : X_t \to X$ and $g' : \bar{X} \to X$ be the canonical arrows. Viewed vis-à-vis these two maps, the canonical arrow

$$\mathsf{R}g'_*(E|\bar{X}) \to \mathsf{R}g_*(E|X_t) \tag{5.2.2.2}$$

is an isomorphism by the local-acyclicity hypothesis. Indeed, we may assume that S is strictly local and integral, with closed point s, and that t is a geometric generic point. Compute the fiber of (5.2.2.2) at a geometric point x of X, with image y in S. After replacing S by the strict localization of S at y, we may assume that $y = s$. Since $\bar{S} \to S$ is an inverse limit of finite morphisms and is radicial at s, we find that $\mathsf{R}g'_*(E|\bar{X})_x = E_x$ and that the fiber of (5.2.2.2) at x identifies with the restriction $E_x = \mathsf{R}\Gamma(X(x), E) \to \mathsf{R}\Gamma(X(x)_t, E|X(x)_t)$, which is an isomorphism by hypothesis. Applying $\mathsf{R}\Gamma(X, -)$ to (5.2.2.2), we deduce that the restriction arrow (5.2.1.3) is an isomorphism. We define (5.2.2.1) as the composite of the inverse of (5.2.1.3) with the base-change arrow (5.2.1.2).

5.2.3

If $s'' \xrightarrow{u'} s' \xrightarrow{u} s$ are specialization arrows of geometric points of S, one verifies that

$$\mathrm{sp}(u')\,\mathrm{sp}(u'') = \mathrm{sp}(uu'),$$
$$\mathrm{cosp}(u)\,\mathrm{cosp}(u') = \mathrm{cosp}(uu'),$$

whenever both sides are defined.

5.2.4

Suppose that the formation of $\mathsf{R}f_*E$ commutes with every finite base change and that f is locally acyclic rel. to E. It follows from the definitions that, for every specialization $u : t \to S(s)$ of geometric points of S, the arrows $\mathrm{sp}(u)$ and $\mathrm{cosp}(u)$ are isomorphisms, inverse to one another.

The preceding hypotheses hold in particular when A is noetherian and annihilated by an integer n invertible on S, when f is proper and smooth, and when E has locally constant cohomology (cohomological properness of proper morphisms (5.1.3), and local acyclicity of smooth morphisms [2, XV]). This recovers the "specialization theorem" [2, XVI 2.1].

On the other hand, 5.1.1 has the following consequence:

Proposition 5.2.5. *Suppose that f is locally acyclic relative to E and that, for every specialization $u : t \to S(s)$, the cospecialization arrow $\mathrm{cosp}(u)$ is an isomorphism. Then the formation of $\mathsf{R}f_*E$ commutes with every finite base change.*

In view of 5.2.4, 5.2.5 generalizes (Étale cohomology 5.1.7).

Corollary 5.2.6. *Suppose that f is locally acyclic rel. to E. Let x be a geometric point of X, with image s in S, and denote by $f_{(x)} : X(x) \to S(s)$ the morphism induced by f. Then the formation of $\mathsf{R}f_{(x)_*}(E|X(x))$ commutes with every finite base change $S' \to S(s)$.*

By 5.2.5, it is enough to verify that the cospecialization arrows for $(f_{(x)}, E|X(x))$ are isomorphisms. By the transitivity of the cospecialization arrows (5.2.3), it is enough to show that if $u : t \to S(s)$ is a specialization, then $\mathrm{cosp}(u) : \mathsf{R}\Gamma(X(x)_t, E|X(x)_t) \to \mathsf{R}\Gamma(X(x)_s, E|X(x)_s)$ is an isomorphism. But since s is closed in $S(s)$, $X(x)_s$ is strictly local with closed point x, $\mathsf{R}\Gamma(X(x)_s, E|X(x)_s) = E_x$, and $\mathrm{cosp}(u)$ is an isomorphism, inverse to the restriction isomorphism $E_x \to \mathsf{R}\Gamma(X(x)_t, E|X(x)_t)$.

Corollary 5.2.7. *Let $f : X \to Y$ be an S-morphism, let $p : X \to S$, $q : Y \to S$ be the projections, and let $E \in \mathrm{Ob}\,\mathsf{D}^+(X)$. Suppose that A is locally constant, that f is locally acyclic rel. to E, and that q is locally acyclic at every geometric point y of Y rel. to every sheaf locally constant in a neighborhood of y. Then p is locally acyclic relative to E.*

Let x be a geometric point of x, with images y and s in Y and S, let $t \to S(s)$ be a specialization, and let $f_{(x)} : X(x) \to Y(y)$ be the morphism induced by f. We must show that the restriction

$$E_x \to \mathsf{R}\Gamma(X(x)_t, E|X(x)_t) \qquad (*)$$

is an isomorphism. We may assume that A is constant. By 5.2.4 and 5.2.5, for every specialization $z \to Y(y)$, the specialization arrow

$$E_x = \mathsf{R}f_{(x)_*}(E|X(x))_y \to \mathsf{R}f_{(x)_*}(E|X(x)|_z = \mathsf{R}\Gamma(X(x)_z, E|X(x)_z)$$

is an isomorphism; in other words, $\mathsf{R}f_{(x)_*}(E|X(x))$ is constant with value E_x. The acyclicity hypothesis on q therefore plays the decisive rôle and ensures that the restriction

$$E_x \to \mathsf{R}\Gamma(Y(y)_y, (E_x)|Y(y)_t) = \mathsf{R}\Gamma\left(Y(y)_t, \mathsf{R}f_{(x)_*}(E|X(x))|Y(y)_t\right)$$

is an isomorphism. But this arrow identifies with $(*)$, which proves the assertion.

The hypothesis of 5.2.7 on q holds in particular when q is smooth and A is annihilated by an integer n invertible on S [2, XV]. On the other hand, if the hypotheses of 5.2.7 hold after every base change $S' \to S$, then it follows that p is universally locally acyclic rel. to E. These remarks imply, in particular, the statement of 2.14.

Corollary 5.2.8. *Let $f : X \to S$ and $E \in \mathrm{Ob}\,\mathsf{D}^+(X)$. Suppose that f is universally locally acyclic rel. to E, that the formation of $\mathsf{R}f_*E$ commutes with every finite base change, and that, for every morphism $s' \to s$, where s is a geometric point of S and s' is the spectrum of a separably closed field, the base-change arrow $\mathsf{R}\Gamma(X_s, E|X_s) \to \mathsf{R}\Gamma(X_{s'}, E|X_{s'})$ is an isomorphism. Then (f, E) is cohomologically proper (5.1.3).*

Let $f' : X' \to S'$ be the morphism deduced from f by a base change $S' \to S$; we must show that the formation of $\mathsf{R}f'_*(E|X')$ commutes with every finite base change. By 5.2.5, it is enough to show that, for every specialization $u' : t' \to S'(s')$, the cospecialization arrow $\mathrm{cosp}(u')$: $\mathsf{R}\Gamma(X'_{t'}, E|X'_{t'}) \to \mathsf{R}\Gamma(X'_{s'}, E|X'_{s'})$

is an isomorphism. Let s (resp. t) be the geometric point that is the image of s (resp. t) in S, and let $u : t \to S(s)$ be the specialization defined by u'. One readily sees that there is a commutative square

$$\begin{array}{ccc} \mathsf{R}\Gamma(X_t, E|X_t) & \xrightarrow{\mathrm{cosp}(u)} & \mathsf{R}\Gamma(X_s, E|X_s) \\ \downarrow & & \downarrow \\ \mathsf{R}\Gamma(X'_{t'}, E|X'_{t'}) & \xrightarrow{\mathrm{cosp}(u')} & \mathsf{R}\Gamma(X'_{s'}, E|X'_{s'}) \end{array}$$

in which the vertical arrows are the base-change arrows. By hypothesis, these are isomorphisms. On the other hand, (5.2.4) $\mathrm{cosp}(u)$ is an isomorphism, hence $\mathrm{cosp}(u')$ is an isomorphism, which completes the proof.

Here is an example of an application of 5.2.8. Suppose that A is annihilated by an integer n invertible on S, and that f is locally of finite type and universally locally acyclic. Let x be a geometric point of X, with image s in S, and let $f_{(x)} : X(x) \to S(s)$ be the morphism induced by f. It follows from 5.2.6 and 1.9 (by passage to the limit) that the hypotheses of 5.2.8 are satisfied by the pair $(f_{(x)}, E|X(x))$, which is therefore cohomologically proper.

5.2.9

Suppose that A is constant. Let $f : X \to S$, and let $E \in \mathrm{Ob}\,\mathsf{D}^+(X)$ be a complex of finite tor-dimension. We say that f is *strongly locally acyclic* rel. to E if, for every geometric point x of X, with image s in S, every specialization $t \to S(s)$, and every A°-module M, the restriction arrow

$$E_x \overset{\mathsf{L}}{\otimes}_A M \to \mathsf{R}\Gamma(X(x)_t, (E|X(x)_t) \overset{\mathsf{L}}{\otimes}_A M)$$

is an isomorphism. I do not know whether "locally acyclic" implies "strongly locally acyclic."

Proposition 5.2.10. *Under the hypotheses of 5.2.9, suppose that A is noetherian and torsion, that S is noetherian, and that f is strongly locally acyclic rel. to E. Then, for every diagram with cartesian squares*

$$\begin{array}{ccccc} X & \xleftarrow{j} & X' & \xleftarrow{j'} & X'' \\ \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f'} & & \downarrow{\scriptstyle f''} \\ S & \xleftarrow{i} & S' & \xleftarrow{i'} & S'', \end{array}$$

with i quasi-finite and i' an open immersion, and every $F \in \mathrm{Ob}\,\mathsf{D}^+(S'', A^\circ)$, the canonical arrow

$$j^* E \overset{\mathsf{L}}{\otimes} f'^* \mathsf{R}i'_* F \to \mathsf{R}j'_*((jj')^* E \overset{\mathsf{L}}{\otimes} f''^* F) \qquad (*)$$

is an isomorphism.

Compare this statement with [2, XV 1.17].

Let us prove 5.2.10. We readily reduce to the case where $S = S'$ is strictly local, and to F constructible and concentrated in degree 0. We then resolve F on the right by finite sums of sheaves of the form $u_* M$, where $u : t \to S$ is a geometric point and M is an A°-module. The hypothesis, vis-à-vis this resolution, implies that $(*)$ is an isomorphism for $F = u_* M$, and the result follows.

Chapter 8

Derived categories

1 Triangulated categories: definitions and examples

1.1 Definition of triangulated categories

1.1.0

Let $\mathcal{A}$ be an additive category and let T be an additive automorphism of $\mathcal{A}$. For two objects X and Y of $\mathcal{A}$, we set

$$\hom^i(X,Y) = \hom_{\mathcal{A}}(X, T^i(Y)) \qquad i \in \mathbb{Z}$$

Let X, Y, and Z be three objects of $\mathcal{A}$, let $\alpha \in \hom^i(X,Y)$, and let $\beta \in \hom^j(X,Y)$. We define the composite $\beta \circ \alpha$ belonging to $\hom^{i+j}(X,Z)$ by

$$\beta \circ \alpha = \beta \circ T^i(\alpha).$$

One checks that this gives a new category whose groups of morphisms between objects are graded. By an abuse of language, this new category will be called the category $\mathcal{A}$ graded by the translation functor T.

Let $\mathcal{A}$ be a category graded by a translation functor T. Whenever a morphism is named or denoted without its degree being specified, it will always mean a morphism of degree zero.

Let $\mathcal{A}$ and $\mathcal{A}'$ be two additive categories graded by the functors T and T', and let F be an additive functor from $\mathcal{A}$ to $\mathcal{A}'$. We say that F *is graded* if an isomorphism of functors* has been specified:

$$F \circ T = T' \circ F$$

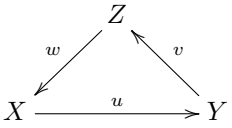
The definition of morphisms of graded functors is given in 4.1.1.

Let $\mathcal{A}$ be an additive category graded by the functor T. A triangle is a collection of three objects X, Y, Z and three morphisms $u : X \to Y$, $v : Y \to Z$, $w : Z \to T(X)$ ($\deg w = 1$). We use either the

by Jean-Louis Verdier

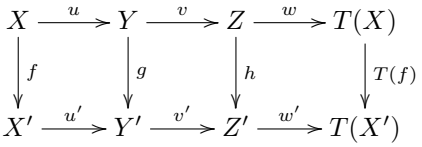
*Text amended in 1976: the original text required an equality $F \circ T = T' \circ F$. The case of functors in several variables is discussed in [2, XVIII 0.2]. It raises a problem of signs.

notation (X, Y, Z, u, v, w) or the following diagram for a triangle:



$\deg(w) = 1$

Let (X, Y, Z, u, v, w) and (X', Y', Z', u', v', w') be two triangles of $\mathcal{A}$. A morphism from the first triangle to the second is a collection of three morphisms $f : X \to X'$, $g : Y \to Y'$, $h : Z \to Z'$ such that the following diagram is commutative:



1.1.1

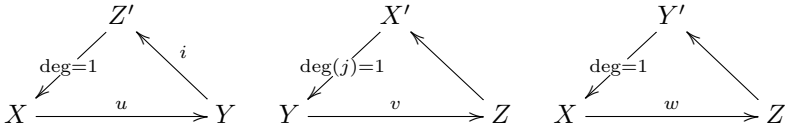
A *triangulated category* is an additive category graded by a translation functor and equipped with a family of triangles, called the family of distinguished triangles. This family must also satisfy the following axioms.

TR1 Every triangle isomorphic to a distinguished triangle is distinguished. Every morphism $u : X \to Y$ is contained in a distinguished triangle (X, Y, Z, u, v, w). The triangle $(X, X, 0, \mathrm{id}_{X'}, 0, 0)$ is distinguished.

TR2 A triangle (X, Y, Z, u, v, w) is distinguished if and only if $(Y, Z, T(X), v, w, -T(u))$ is distinguished.

TR3 If (X, Y, Z, u, v, w) and (X', Y', Z', u', v', w') are distinguished, then for every morphism $(f, g) : u \to u'$, there exists a morphism $h : Z \to Z'$ such that (f, g, h) is a morphism of triangles.

TR4



If these are three distinguished triangles such that $w = v \circ u$, then there exist two morphisms $f : Z' \to Y'$, $g : Y' \to X'$ such that

1. (id_X, v, f) is a morphism of triangles;
2. (u, id_Z, g) is a morphism of triangles;
3. $(Z', Y', X', f, g, T(i)j)$ is a distinguished triangle.

If $\mathcal{C}$ and $\mathcal{C}'$ are two triangulated categories, an *exact functor* from $\mathcal{C}$ to $\mathcal{C}'$ is an additive graded functor that takes distinguished triangles to distinguished triangles. Morphisms of exact functors are morphisms of graded functors.

The following property follows immediately from axioms TR1, TR2, and TR3.

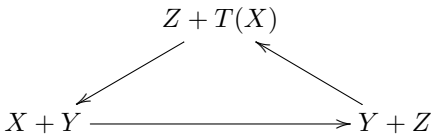
Proposition 1.1.2. *Let (X, Y, Z, u, v, w) be a distinguished triangle and let M be an object of a triangulated category. Then the following sequences are exact:*

$$\cdots \longrightarrow \hom^i(M, X) \xrightarrow{\hom(M,u)} \hom^i(M, Y) \xrightarrow{\hom(M,v)} \hom^i(M, Z) \xrightarrow{\hom(M,w)} \hom^{i+1}(M, X) \longrightarrow \cdots$$

$$\cdots \longrightarrow \hom^i(Z, M) \xrightarrow{\hom(v,M)} \hom^i(Y, M) \xrightarrow{\hom(u,M)} \hom^i(X, M) \xrightarrow{\hom(w,M)} \hom^{i+1}(Z, M) \longrightarrow \cdots$$

From this proposition one obtains statements of the following kind:

- If (f, g, h) is a morphism of distinguished triangles and f, g are isomorphisms.
- The distinguished triangles constructed on a morphism (TR1) are all isomorphic (*but the isomorphisms are not, in general, uniquely determined*).
- When one of the morphisms in a distinguished triangle has a kernel or a cokernel, the latter splits; that is, the triangle is of the form



- The sum of two distinguished triangles is distinguished. (One uses axiom TR4.)

1.2 Examples

1.2.1

We first fix some notation. Let $\mathcal{A}$ be an additive category. The following category will be denoted by $\mathsf{C}(\mathcal{A})$:

- The objects of $\mathsf{C}(\mathcal{A})$ are the complexes of $\mathcal{A}$, with no restriction on degree and with differential of degree $+1$.
- The morphisms of $\mathsf{C}(\mathcal{A})$ are the degree-preserving morphisms of complexes (those commuting with the differential).

Let T be the following functor. For every object $X^\bullet$ of $\mathsf{C}(\mathcal{A})$,

$$T(X^\bullet)_i = (X^\bullet)_{i+1}$$
$$d_i(T(X^\bullet)) = -d_{i+1}(X^\bullet).$$

On morphisms the functor T acts as follows: for every morphism $f : X^\bullet \to Y^\bullet$, the morphism $T(f) : T(X^\bullet) \to T(Y^\bullet)$ is defined by

$$T(f)_i = f_{i+1}.$$

It is immediate that T is an additive automorphism of $\mathsf{C}(\mathcal{A})$. The morphisms of degree n defined using this translation functor are then the morphisms that raise degree by n and commute or anticommute with the differential according to the parity of n. Thus one recovers the usual definition.

Let $\mathscr{C}$ denote the following family of triangles. A triangle $(X^\bullet, Y^\bullet, Z^\bullet, u, v, w)$ belongs to the family if[†]

[†]Text amended in 1976 to ensure the validity of 1.2.4.

- $Z^\bullet$ is the simple complex associated with the double complex

$$\cdots \longrightarrow 0 \longrightarrow X^\bullet \xrightarrow{u} Y^\bullet \longrightarrow 0 \longrightarrow \cdots$$

in which the objects of $Y^\bullet$ have first degree zero and the objects of $X^\bullet$ have first degree -1.

- v is the image, under the functor: double complex $\mapsto$ simple complex, of the following morphism of double complexes:

$$\begin{array}{ccccccccc} \cdots & \longrightarrow & 0 & \longrightarrow & 0^\bullet & \longrightarrow & Y^\bullet & \longrightarrow & 0 & \longrightarrow & \cdots \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \\ \cdots & \longrightarrow & 0 & \longrightarrow & X^\bullet & \longrightarrow & Y^\bullet & \longrightarrow & 0 & \longrightarrow & \cdots \end{array}$$

- w is the negative of the image, under the same functor, of the following morphism of double complexes:

$$\begin{array}{ccccccccc} \cdots & \longrightarrow & 0 & \longrightarrow & X^\bullet & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & \cdots \\ & & \uparrow & & \uparrow & & \uparrow & & \uparrow & & \\ \cdots & \longrightarrow & 0 & \longrightarrow & X^\bullet & \longrightarrow & Y^\bullet & \longrightarrow & 0 & \longrightarrow & \cdots \end{array}$$

1.2.2

The set of null-homotopic morphisms is a two-sided ideal (if f and g are composable and either f or g is null-homotopic, then the composite is null-homotopic; if f and g are null-homotopic, then $f \oplus g$ is null-homotopic). For every pair of objects $X^\bullet$, $Y^\bullet$, let $\mathrm{Htp}(X^\bullet, Y^\bullet)$ denote the subgroup of $\hom_{\mathsf{C}(\mathcal{A})}(X^\bullet, Y^\bullet)$ consisting of the null-homotopic morphisms. The objects of $\mathsf{K}(\mathcal{A})$ are then the objects of $\mathsf{C}(\mathcal{A})$, and its group of morphisms with source $X^\bullet$ and target $Y^\bullet$ is

$$\hom_{\mathsf{C}(\mathcal{A})}(X^\bullet, Y^\bullet) / \mathrm{Htp}(X^\bullet, Y^\bullet).$$

The composition law on the morphisms of $\mathsf{K}(\mathcal{A})$ is defined by passing the composition law on the morphisms of $\mathsf{C}(\mathcal{A})$ to the quotient. The category $\mathsf{K}(\mathcal{A})$ is additive. The translation functor T on $\mathsf{C}(\mathcal{A})$ passes to the quotient (the translate of a null-homotopic morphism is null-homotopic). The resulting functor is an additive automorphism of $\mathsf{K}(\mathcal{A})$, again denoted by T. By an abuse of notation, $\mathsf{K}(\mathcal{A})$ will henceforth denote the category $\mathsf{K}(\mathcal{A})$ graded by the functor T.

A distinguished triangle in $\mathsf{K}(\mathcal{A})$ is any triangle *isomorphic* to a triangle arising from $\mathscr{C}$. The family of distinguished triangles satisfies axioms TR1, TR2, TR3, and TR4. By an abuse of notation, $\mathsf{K}(\mathcal{A})$ will denote the category $\mathsf{K}(\mathcal{A})$ triangulated by the family of triangles defined above.

1.2.3

There is also a whole arsenal of subcategories:

- A complex is said to be bounded below if all but finitely many of its objects of negative degree are zero. Bounded-above and bounded complexes are defined similarly. Let $\mathsf{K}^+(\mathcal{A})$, $\mathsf{K}^-(\mathcal{A})$, and $\mathsf{K}^b(\mathcal{A})$ denote the full subcategories of $\mathsf{K}(\mathcal{A})$ generated by these families of objects. These subcategories are "*triangulated subcategories*" of $\mathsf{K}(\mathcal{A})$: every distinguished triangle two of whose objects belong to the subcategory is isomorphic to a triangle all three of whose objects belong to the subcategory.

- Suppose that $\mathcal{A}$ is an abelian category. A complex is said to be cohomologically bounded below if all but finitely many of its cohomology objects of negative degree are zero. Cohomologically bounded-above complexes, cohomologically bounded complexes, and acyclic complexes are defined similarly. Let $\mathsf{K}^{\infty,+}(\mathcal{A})$, $\mathsf{K}^{\infty,-}(\mathcal{A})$, $\mathsf{K}^{\infty,b}(\mathcal{A})$, and $\mathsf{K}^{\infty,\varnothing}(\mathcal{A})$ denote the full subcategories generated by these families of objects. They are triangulated subcategories.

  We shall also use the triangulated subcategories $\mathsf{K}^{+,b}(\mathcal{A})$, $\mathsf{K}^{+,\varnothing}(\mathcal{A})$, ... etc ... (the first superscript gives information about the objects of the complexes, and the second about the cohomology objects).

- Without assuming that $\mathcal{A}$ is abelian, let O be a set of objects of $\mathcal{A}$ stable under isomorphisms and direct sums. Let $O(\mathcal{A})$ denote the full subcategory of $\mathsf{C}(\mathcal{A})$ generated by the complexes whose objects in every degree belong to O. Let $\underline{O}(\mathcal{A})$ denote the corresponding triangulated subcategory of $\mathsf{K}(\mathcal{A})$. When $\mathcal{A}$ is abelian, one may take for O either the set I of injectives or the set P of projectives.

1.2.4

The category $\mathsf{K}(\mathcal{A})$ is uniquely determined by the data of $\mathsf{C}(\mathcal{A})$ and the family $\mathscr{C}$. More precisely, every graded additive functor from $\mathsf{C}(\mathcal{A})$ to a triangulated category that takes every triangle of $\mathscr{C}$ to a distinguished triangle factors uniquely through $\mathsf{K}(\mathcal{A})$, and the resulting functor is exact.

For every complex $X^\bullet$ of $\mathsf{C}(\mathcal{A})$, let $\bar{X}^\bullet$ denote the complex obtained from $X^\bullet$ by setting the differential equal to zero. A three-term sequence

$$0 \longrightarrow X^\bullet \longrightarrow Y^\bullet \longrightarrow Z^\bullet \longrightarrow 0$$

is called a semi-split sequence if the sequence

$$0 \longrightarrow \bar{X}^\bullet \longrightarrow \bar{Y}^\bullet \longrightarrow \bar{Z}^\bullet \longrightarrow 0$$

is split; that is, if it is isomorphic to the sequence

$$0 \longrightarrow \bar{X}^\bullet \longrightarrow \bar{X}^\bullet + \bar{Z}^\bullet \longrightarrow \bar{Z}^\bullet \longrightarrow 0.$$

Let $0 \to X^\bullet \to Y^\bullet \to Z^\bullet \to 0$ be a semi-split sequence. Choose a splitting, that is, for every n an isomorphism

$$(Y^\bullet)^n \simeq (X^\bullet)^n + (Z^\bullet)^n.$$

The matrix of the differential of $Y^\bullet$ in the above direct-sum decomposition has the form

$$\begin{pmatrix} d_{X^\bullet} & \varphi_n \\ 0 & d_{Y^\bullet} \end{pmatrix}$$

where φ_n is a morphism from $(Z^\bullet)^n$ to $(X^\bullet)^{n+1}$. The φ_n determine a morphism of complexes

$$\varphi : Z^\bullet \to T(X^\bullet).$$

When the splitting is changed, the homotopy class of φ does not change. Moreover, if $\underline{u}$, $\underline{v}$, and $\underline{\varphi}$ denote the images in $\mathsf{K}(\mathcal{A})$ of the morphisms u, v, and φ, then the triangle $(X^\bullet, Y^\bullet, Z^\bullet, \underline{u}, \underline{v}, \underline{\varphi})$ is distinguished. Let $\mathsf{SSS}(\mathcal{A})$ denote the category of semi-split sequences of $\mathsf{C}(\mathcal{A})$ and let $\mathsf{TrK}(\mathcal{A})$ denote the category of distinguished triangles of $\mathsf{K}(\mathcal{A})$. The preceding construction defines a functor

$$\rho : \mathsf{SSS}(\mathcal{A}) \to \mathsf{TrK}(\mathcal{A}).$$

This functor is essentially surjective.

1.3 Examples of cohomological and exact functors

Definition 1.3.1. *Let $\mathcal{A}$ be a triangulated category and let $\mathcal{B}$ be an abelian category. An additive functor $F : \mathcal{A} \to \mathcal{B}$ is called a* cohomological functor *if, for every distinguished triangle (X, Y, Z, u, v, w), the sequence*

$$F(X) \xrightarrow{F(u)} F(Y) \xrightarrow{F(v)} F(Z)$$

is exact.

The functor $F \circ T^i$ will often be denoted by F^i. By axiom TR2 for triangulated categories, there is an unbounded exact sequence

$$\cdots \longrightarrow F^i(X) \longrightarrow F^i(Y) \longrightarrow F^i(Z) \longrightarrow F^{i+-}(X) \longrightarrow \cdots$$

1.3.2 Examples

1. Let $\mathcal{A}$ be a triangulated category. For every object X of $\mathcal{A}$, the functor $\hom_{\mathcal{A}}(X, -)$ is cohomological. The functor $\hom_{\mathcal{A}}(-, X)$ is a cohomological functor $\mathcal{A}^\circ \to \mathsf{Ab}$.

2. Let $\mathcal{A}$ be an abelian category and let $\mathsf{C}(\mathcal{A})$ be the category of complexes of $\mathcal{A}$. Define the functor $\mathrm{H}^0 : \mathsf{C}(\mathcal{A}) \to \mathcal{A}$ as follows. For an object $X^\bullet$ of $\mathsf{C}(\mathcal{A})$, set

   $$\mathrm{H}^0(X^\bullet) = \ker d^0 / \operatorname{im} d^{-1}.$$

   The functor H^0 annihilates null-homotopic morphisms and therefore factors uniquely through $\mathsf{K}(\mathcal{A})$. The resulting functor will again be denoted by $\mathrm{H}^0 : \mathsf{K}(\mathcal{A}) \to \mathcal{A}$.

1.3.3 Example of an exact bifunctor

Let $\mathcal{A}$, $\mathcal{A}'$, and $\mathcal{A}''$ be three additive categories, and let

$$P : \mathcal{A} \times \mathcal{A}' \to \mathcal{A}''$$

be a bilinear functor (that is, additive in each argument separately). It induces the bilinear functor

$$P^* : \mathsf{C}(\mathcal{A}) \times \mathsf{C}(\mathcal{A}') \to \mathsf{C}(\mathcal{A}'')$$

as follows.

Let $X^\bullet$ be an object of $\mathsf{C}(\mathcal{A})$ and let $Y^\bullet$ be an object of $\mathsf{C}(\mathcal{A}')$. Then $P(X^\bullet, Y^\bullet)$ is a double complex of $\mathcal{A}''$. Set $P^*(X^\bullet, Y^\bullet) =$ the simple complex associated with $P(X^\bullet, Y^\bullet)$.

Let f be a null-homotopic morphism of $\mathsf{C}(\mathcal{A})$ (respectively $\mathsf{C}(\mathcal{A}')$), and let $Z^\bullet$ be an object of $\mathsf{C}(\mathcal{A}')$ (respectively $\mathsf{C}(\mathcal{A})$). The morphism $P^*(f, Z^\bullet)$ (respectively $P^\bullet(Z^\bullet, f)$) is then null-homotopic. It follows that P^* uniquely defines a functor

$$P^\bullet : \mathsf{K}(\mathcal{A}) \times \mathsf{K}(\mathcal{A}') \to \mathsf{K}(\mathcal{A}'').$$

The bifunctor $P^\bullet$ is exact.

In particular, let $\mathcal{A}$ be an additive category. For P one may take the functor

$$\begin{aligned} \mathcal{A}^\circ \times \mathcal{A} &\to \mathsf{Ab} \\ (X, Y) &\mapsto \hom(X, Y) \end{aligned}$$

The preceding construction then gives a functor

$$\hom^\bullet : \mathsf{K}(\mathcal{A})^\circ \times \mathsf{K}(\mathcal{A}) \to \mathsf{K}(\mathsf{Ab})$$

which, when composed with the functor $\mathrm{H}^0 : \mathsf{K}(\mathsf{Ab}) \to \mathsf{Ab}$, plainly gives back the functor $\hom_{\mathsf{K}(\mathcal{A})}$.

2 Quotient categories

2.1 Thick subcategories. Multiplicative systems of morphisms

We begin with two definitions.

Definition 2.1.1. *A subcategory $\mathcal{B}$ of a triangulated category $\mathcal{A}$ is said to be* thick *if $\mathcal{B}$ is a full triangulated subcategory of $\mathcal{A}$ and, in addition, $\mathcal{B}$ has the following property:*

For every morphism $f : X \to Y$ that factors through an object of $\mathcal{B}$ and is contained in a distinguished triangle (X, Y, Z, f, g, h) in which Z is an object of $\mathcal{B}$, the source of f and the target of f are objects of $\mathcal{B}$.

The set of thick subcategories of $\mathcal{A}$ will be denoted by $\mathscr{N}$.

The intersection of an arbitrary family of thick subcategories is a thick subcategory.

Definition 2.1.2. *Let $\mathcal{A}$ be a triangulated category. A set S of morphisms of $\mathcal{A}$ is called a* multiplicative system of morphisms *if it has the following five properties.*

FR1 *If $f, g \in S$ and f and g are composable, then $f \circ g \in S$. For every object X of $\mathcal{A}$, the identity morphism of X belongs to S.*

FR2 *In the category $\mathcal{A}$, every diagram*

$$\begin{array}{ccc} & & Y \\ & & \downarrow{\scriptstyle s\in S} \\ Z & \xrightarrow{f} & X \end{array}$$

can be completed to a commutative diagram

$$\begin{array}{ccc} P & \xrightarrow{g} & Y \\ \downarrow{\scriptstyle t\in S} & & \downarrow{\scriptstyle s\in S} \\ Z & \xrightarrow{f} & X \end{array}$$

Moreover, the symmetric property holds.

FR3 *If f and g are morphisms, the following properties are equivalent:*

i) there exists $s \in S$ such that $s \circ f = s \circ g$;

ii) there exists $t \in S$ such that $f \circ t = g \circ t$.

FR4 *Let T be the translation functor of $\mathcal{A}$. For every element s of S, one has $T(s) \in S$.*

FR5 *Let (X, Y, Z, u, v, w) and (X', Y', Z', u', v', w') be two distinguished triangles, and let f and g be two elements of S such that the pair (f, g) is a morphism from u to u'. There exists a morphism $h \in S$ such that (f, g, h) is a morphism of triangles.*

A multiplicative system of morphisms is said to be *saturated* if it has the following property:

A morphism f belongs to S if and only if there exist two morphisms g and g' such that $g \circ f \in S$ and $f \circ g' \in S$.

The intersection of an arbitrary family of saturated multiplicative systems is a saturated multiplicative system.

The set of saturated multiplicative systems will be denoted by $\mathscr{S}$.

Let $\mathcal{B}$ be a thick subcategory. Denote by $\varphi(\mathcal{B})$ the set of morphisms f contained in a distinguished triangle (X, Y, Z, f, g, h) in which Z is an object of $\mathcal{B}$. Then $\varphi(\mathcal{B})$ is a saturated multiplicative system.

Let S be a saturated multiplicative system. Denote by $\psi(S)$ the full subcategory generated by the objects Z contained in a distinguished triangle (X, Y, Z, f, g, h) in which f is an element of S. The subcategory $\psi(S)$ is thick.

The main result of this subsection is the following: φ is an order-preserving isomorphism from $\mathscr{N}$ onto $\mathscr{S}$, where the order relation is defined by inclusion. Its inverse is precisely ψ.

2.2 Universal problems

Let $\mathcal{A}$ and $\mathcal{A}'$ be two triangulated categories and let F be an exact functor from $\mathcal{A}$ to $\mathcal{A}'$. Let $S(F)$ be the set of morphisms of $\mathcal{A}$ that F takes to isomorphisms, and let $\mathcal{B}(F)$ be the full subcategory generated by the objects of $\mathcal{A}$ that F takes to zero objects of $\mathcal{A}'$. Then $S(F)$ is a saturated multiplicative system and $\mathcal{B}(F)$ is a thick subcategory. Moreover, $S(F) = \varphi(\mathcal{B}(F))$. Now let $\mathcal{A}$ be a triangulated category, let $\mathcal{B}$ be a thick subcategory, and let $S = \varphi(\mathcal{B})$ be the corresponding saturated multiplicative system. The following two universal problems are equivalent.

Problem 1 Find a triangulated category $\mathcal{A}/\mathcal{B}$ and an exact functor $Q : \mathcal{A} \to \mathcal{A}/\mathcal{B}$ such that every exact functor from $\mathcal{A}$ to a triangulated category $\mathcal{A}'$ that takes the objects of $\mathcal{B}$ to zero objects of $\mathcal{A}'$ admits a unique factorization of the form $G \circ Q$, where G is exact.

Problem 2 Find a triangulated category $\mathcal{A}_S$ and an exact functor $Q : \mathcal{A} \to \mathcal{A}_S$ such that every exact functor from $\mathcal{A}$ to a triangulated category $\mathcal{A}'$ that takes the morphisms of S to isomorphisms of $\mathcal{A}'$ admits a unique factorization of the form $G \circ Q$, where G is exact.

(The author asks the reader to excuse this use of obsolete and reactionary language.) In the next subsection we shall show that Problem 2 has a solution. Consequently, the corresponding Problem 1 has the same solution.

2.3 Calculus of fractions

2.3.1

Let $\mathcal{A}$ be a triangulated category and let S be a saturated multiplicative system. Denote by $\mathcal{A}[S^{-1}]$ the category of fractions of $\mathcal{A}$ with respect to the set of morphisms S, and by Q the canonical functor from $\mathcal{A}$ to $\mathcal{A}[S^{-1}]$. The pair $(\mathcal{A}[S^{-1}], Q)$ solves the following problem: every functor from $\mathcal{A}$ to an arbitrary category (not necessarily additive) that takes morphisms of S to isomorphisms factors uniquely through $(\mathcal{A}[S^{-1}], Q)$. Such a pair always exists, without any hypothesis on the set of morphisms S [18, 1.1][‡]. However, because the set of morphisms S is a saturated multiplicative system, it has properties FR1, FR2, and FR3. Consequently, by [18], the category $\mathcal{A}[S^{-1}]$ can be obtained by a right or left calculus of

[‡]The original text references [C.G.G] here. Most likely, this is the lost work *Catégories et foncteurs* by Chevalley, Gabriel and Grothendieck, referenced in[31].

fractions. We recall how $\mathcal{A}[S^{-1}]$ is obtained by a right calculus of fractions. (The left calculus of fractions is obtained by reversing the arrows.)

2.3.2

The objects of $\mathcal{A}[S^{-1}]$ are the objects of $\mathcal{A}$.

- For every object X of $\mathcal{A}$, let S_X denote the category of arrows belonging to S and having target X. To every object Y of $\mathcal{A}$ one associates, functorially in Y, the following set-valued functor on S_X° (S_X° denotes the opposite category):

$$H_Y : s \mapsto \hom(\text{source}(s), Y).$$

  Set

$$\hom_{\mathcal{A}[S^{-1}]}(X, Y) = \varinjlim_{S_X^\circ} H_Y.$$

  For all matters concerning direct limits, we refer to [1].

  One then observes with pleasure, using FR1, FR2, and FR3, that the category S_X° has properties L1, L2, and L3. Direct limits therefore have all the good properties of direct limits over filtered ordered sets.

- Let X, Y, and Z be three objects of $\mathcal{A}$, let a be an element of $\hom_{\mathcal{A}[S^{-1}]}(X, Y)$, and let b be an element of $\hom_{\mathcal{A}[S^{-1}]}(Y, Z)$. Let s be an object of S_X, let $\underline{a}$ be an element of $\hom(\text{source}(s), Y)$ whose image is a, and let an object of S_y, $\underline{b}$ be an element of $\hom(\text{source}(t), Z)$ whose image is b. There is then a diagram

(1)

  which, by FR2, can be completed to a diagram

  Let $b \circ a$ denote the image in $\hom_{\mathcal{A}[S^{-1}]}(X, Z)$ of the morphism $\underline{b} \circ \underline{c}$. Using properties FR1, FR2, and FR3, one checks that $b \circ a$ is independent of the chosen representatives $\underline{a}$ and $\underline{b}$, and also of the way in which diagram (1) is completed. One further checks that this defines a category $\mathcal{A}[S^{-1}]$.

We denote by Q the evident functor $\mathcal{A} \to \mathcal{A}[S^{-1}]$.

Since $\mathcal{A}$ is additive, $\mathcal{A}[S^{-1}]$ is an additive category. Moreover, using FR4, one proves that there exists a unique translation functor on $\mathcal{A}[S^{-1}]$, denoted by T, satisfying

$$Q \circ T = T \circ Q.$$

Finally, using FR5, one proves that there exists a unique triangulated structure on $\mathcal{A}[S^{-1}]$ for which Q is exact. The distinguished triangles of $\mathcal{A}[S^{-1}]$ are precisely the triangles isomorphic to the images under Q of the distinguished triangles of $\mathcal{A}$. Denoting by $\mathcal{A}_S$ the category $\mathcal{A}[S^{-1}]$ equipped with this triangulated structure, one proves without difficulty that the pair $(\mathcal{A}_S, Q)$ is a solution to Problem 2.

Definition 2.3.3. *Let $\mathcal{A}$ be a triangulated category, let $\mathcal{B}$ be a thick subcategory of $\mathcal{A}$, and let $(Q, \mathcal{A}/\mathcal{B})$ be the solution to Problem 1 (§2.2). The category $\mathcal{A}/\mathcal{B}$ is called the* quotient category *of $\mathcal{A}$ by $\mathcal{B}$, and Q is called the canonical quotient functor. More generally, let $\mathcal{N}$ be a triangulated subcategory of $\mathcal{A}$, and let $\underline{\mathcal{N}}$ be the smallest thick subcategory containing $\mathcal{N}$. By definition, the quotient category of $\mathcal{A}$ by $\mathcal{N}$, denoted $\mathcal{A}/\mathcal{N}$, is $\mathcal{A}/\underline{\mathcal{N}}$.*

2.4 Properties of quotient categories

2.4.1

Let $\mathcal{A}$ be a triangulated category and let H be a cohomological functor with values in an abelian category $\mathcal{G}$. Let $\mathcal{B}_H$ be the full subcategory generated by the objects all of whose translates are taken by H to zero objects of $\mathcal{G}$, and let S_H be the set of morphisms all of whose translates are taken by H to isomorphisms of $\mathcal{G}$. Then $\mathcal{B}_H$ is a thick subcategory of $\mathcal{A}$, and S_H is a saturated multiplicative system. Moreover, $S_H = \varphi(\mathcal{B}_H)$ (§2.1). The functor H factors uniquely through $(Q, \mathcal{A}/\mathcal{B}_H)$.

Theorem 2.4.2. *Let $\mathcal{A}$ be a triangulated category, let $\mathcal{B}$ be a triangulated subcategory, let $\mathcal{N}$ be a thick subcategory of $\mathcal{A}$, and let $S = \varphi(\mathcal{N})$ be the corresponding saturated multiplicative system.*

(a) The category $\mathcal{N} \cap \mathcal{B}$ is a thick subcategory of $\mathcal{B}$. The corresponding multiplicative system is $S \cap \mathcal{B}$.

(b) The following two properties are equivalent:

(i) For every object X of $\mathcal{B}$ and every morphism $s : R \to X$, where s belongs to S, there exists a morphism $s' : R' \to R$ such that $s \circ s'$ belongs to $S \cap \mathcal{B}$; and $R' \in \operatorname{Ob} \mathcal{B}$.

(ii) Every morphism from an object X of $\mathcal{B}$ to an object Y of $\mathcal{N}$ factors through an object of $\mathcal{N} \cap \mathcal{B}$.

(c) The properties (i)' and (ii)' obtained from (i) and (ii) by reversing the arrows are equivalent.

(d) If properties (i) and (ii) hold, or if properties (i)' and (ii)' hold, the canonical functor

$$\mathcal{B}/\mathcal{N} \cap \mathcal{B} \longrightarrow \mathcal{A}/\mathcal{N}$$

is faithful.

Since this functor is injective on objects, it realizes $\mathcal{B}/\mathcal{N} \cap \mathcal{B}$ as a subcategory of $\mathcal{A}/\mathcal{N}$.

(e) If, in addition, $\mathcal{B}$ is a full subcategory of $\mathcal{A}$, then $\mathcal{B}/\mathcal{N} \cap \mathcal{B}$ is a full subcategory of $\mathcal{A}/\mathcal{N}$.

Corollary 2.4.3. *Let $\mathcal{A} \subset \mathcal{B} \subset \mathcal{C}$ be three triangulated categories, with $\mathcal{A}$ a thick subcategory of $\mathcal{B}$ and $\mathcal{B}$ a thick subcategory of $\mathcal{C}$. Then $\mathcal{A}$ is a thick subcategory of $\mathcal{C}$, and $\mathcal{B}/\mathcal{A}$ is a thick subcategory of $\mathcal{C}/\mathcal{A}$. The canonical functor $\mathcal{C}/\mathcal{B} \to (\mathcal{C}/\mathcal{A})/(\mathcal{B}/\mathcal{A})$ is an isomorphism.*

2.5 Properties of the quotient functor

Let $\mathcal{A}$ be a triangulated category, let $\mathcal{B}$ be a thick subcategory, let S be the corresponding multiplicative system, and let $Q : \mathcal{A} \to \mathcal{A}/\mathcal{B}$ be the canonical quotient functor.

Proposition 2.5.1. *For objects X and Y of $\mathcal{A}$, the following assertions are equivalent:*

(a) Every morphism $f : X \to Y$ for which there exists a morphism $s : Z \to X$ in S satisfying $f \circ s = 0$ is zero.

(b) Every morphism $f : X \to Y$ for which there exists a morphism $s : Y \to Z$, $s \in S$, satisfying $s \circ f = 0$ is zero.

(c) Every morphism $f : X \to Y$ that factors through an object of $\mathcal{B}$ is zero.

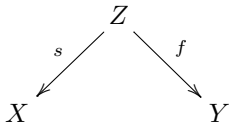
(d) The canonical map

$$\hom_{\mathcal{A}}(X, Y) \to \hom_{\mathcal{A}/\mathcal{B}}(Q(X), Q(Y))$$

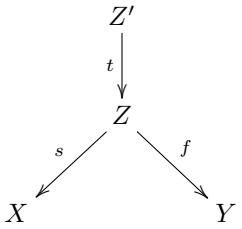
is injective.

Proposition 2.5.2. *Let X and Y be two objects of $\mathcal{A}$. The following assertions are equivalent:*

(a) Every diagram ($s \in S$)



can be completed to a diagram: ($s, t \in S$):



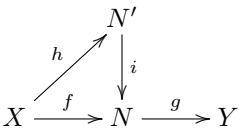
in which $f \circ t$ factors through $(X, s \circ t)$.

(b) The assertion obtained by reversing the direction of the arrows in (a) and interchanging X and Y.

(c) Every diagram

$$X \xrightarrow{f} N \xrightarrow{g} Y$$

in which $g \circ f = 0$ and N is an object of $\mathcal{B}$ can be completed to a diagram



in which $f = i \circ h$ and $g \circ i = 0$.

(d) The assertion obtained by reversing the arrows in (c) and interchanging X and Y.

(e) The canonical map

$$\hom_{\mathcal{A}}(X, Y) \xrightarrow{Q} \hom_{\mathcal{A}/\mathcal{B}}(Q(X), Q(Y))$$

is surjective.

Proposition 2.5.3. *Let X be an object of $\mathcal{A}$. The following assertions are equivalent:*

(a) For every object Y of $\mathcal{A}$, the canonical map

$$\hom_{\mathcal{A}}(X,Y) \xrightarrow{Q} \hom_{\mathcal{A}/\mathcal{B}}(Q(X),Q(Y))$$

is an isomorphism.

(b) Every morphism from X to an object of $\mathcal{B}$ is zero.

Similarly, the following two assertions are equivalent:

(a)' For every object Y of $\mathcal{A}$, the canonical map

$$\hom_{\mathcal{A}}(X,Y) \xrightarrow{Q} \hom_{\mathcal{A}/\mathcal{B}}(Q(X),Q(Y))$$

is an isomorphism.

(b)' Every morphism from an object of $\mathcal{B}$ to X is zero.

Definition 2.5.4. *Every object having the equivalent properties (a) and (b) of the preceding proposition is called an* object free on the left over $\mathcal{A}/\mathcal{B}$, *or a* left Q-free object. *Similarly, every object having the equivalent properties (a)' and (b)' is called an* object free on the right over $\mathcal{A}/\mathcal{B}$, *or a* right Q-free object. *It is determined up to isomorphism by the knowledge of $Q(X) \in \operatorname{Ob} \mathcal{A}/\mathcal{B}$.*

2.6 Functors adjoint to the quotient functor

Definition 2.6.1. *Two triangulated subcategories $\mathcal{N}$ and $\mathcal{N}'$ of a triangulated category $\mathcal{A}$ are said to be* orthogonal *if, for every object X of $\mathcal{N}$ and every object Y of $\mathcal{N}'$, one has*

$$\hom_{\mathcal{A}}(X,Y) = 0$$

The category $\mathcal{N}'$ is then said to be right orthogonal to $\mathcal{N}$, and $\mathcal{N}$ left orthogonal to $\mathcal{N}'$.

Proposition 2.6.2. *Let $\mathcal{N}$ be a triangulated subcategory of a triangulated category $\mathcal{A}$. The full category $\mathcal{N}^{\perp}$ (respectively ${}^{\perp}\mathcal{N}$) generated by the objects X of $\mathcal{A}$ such that, for every object Y of $\mathcal{N}$, $\hom_{\mathcal{A}}(Y,X) = 0$ (respectively $\hom_{\mathcal{A}}(X,Y) = 0$), is a thick subcategory of $\mathcal{A}$. By an abuse of language, the category $\mathcal{N}^{\perp}$ is called the right orthogonal of $\mathcal{N}$.*

This proposition allows us to restate Proposition 2.5.3.

Proposition 2.6.3. *Let $\mathcal{B} \subset \mathcal{A}$ be a thick subcategory of a triangulated category $\mathcal{A}$. The full category generated by the objects free on the right over $\mathcal{A}/\mathcal{B}$ (respectively on the left) is precisely the right (respectively left) orthogonal of $\mathcal{B}$.*

Proposition 2.6.4. *Let $\mathcal{A}$ be a triangulated category, let $\mathcal{B}$ be a thick subcategory of $\mathcal{A}$, let $\mathcal{B}^{\perp}$ be the right orthogonal of $\mathcal{B}$, let $S(\mathcal{B})$ and $s(\mathcal{B}^{\perp})$ be the corresponding multiplicative systems, and let Q and $Q^{\perp}$ be the canonical quotient functors. For an object x of $\mathcal{A}$, consider the following properties:*

(i) X maps by a morphism of $S(\mathcal{B})$ to an object of $\mathcal{B}^{\perp}$.

(ii) X receives, by a morphism of $S(\mathcal{B}^{\perp})$, an object of $\mathcal{B}$.

(iii) The category $S_X(\mathcal{B})$ of arrows of $S(\mathcal{B})$ with source X has a final object.

(iv) The category $S^X(\mathcal{B}^\perp)$ of arrows of $S(\mathcal{B}^\perp)$ with target X has an initial object.

(v) The category $\mathcal{B}/X$ of objects of $\mathcal{B}$ over X has a final object.

(vi) The category $\mathcal{B}^\perp/X$ of objects of $\mathcal{B}^\perp$ under X has an initial object.

Then

$$(i) \Longleftrightarrow (ii) \Longleftrightarrow (iii) \Longleftrightarrow (v) \Rightarrow (iv), \quad (v) \Rightarrow (vi)$$

If, in addition, ${}^\perp(\mathcal{B}^\perp) = \mathcal{B}$, then all the properties are equivalent.

Let $\mathcal{B}$ be a thick subcategory of a triangulated category $\mathcal{A}$, let i be the inclusion functor from $\mathcal{B}$ into $\mathcal{A}$, let Q be the quotient functor from $\mathcal{A}$ to $\mathcal{A}/\mathcal{B}$, let $\mathcal{B}^\perp$ be the right orthogonal of $\mathcal{B}$, and let $i^\perp$ and $Q^\perp$ be the corresponding functors. Proposition 2.6.4 immediately gives the following propositions.

Proposition 2.6.5. *The following two properties are equivalent:*

(i) The functor i has a right adjoint.

(ii) The functor Q has a right adjoint.

The proposition remains true when "right" is replaced by "left."

Proposition 2.6.6. *The following two properties are equivalent:*

(i) The functor i has a right adjoint.

(ii) The functor $i^\perp$ has a left adjoint. The left orthogonal of the category $\mathcal{B}^\perp$ is equal to $\mathcal{B}$.

Proposition 2.6.7. *Suppose the properties of Propositions 2.6.5 and 2.6.6 hold. Let i^* and Q^* be the right adjoints of i and Q. Similarly, let ${}^*i^\perp$ and ${}^*Q^\perp$ be the left adjoints of $i^\perp$ and $Q^\perp$. All these functors are exact. Moreover:*

There is a functorial isomorphism $Q^* \circ Q \xrightarrow{\sim} i^\perp \circ^* i^\perp$ such that the following diagram is commutative:

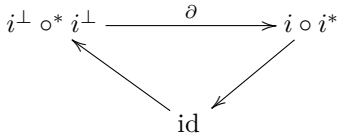
$$\begin{array}{ccc} & \mathrm{id} & \\ \swarrow & & \searrow \\ Q^* \circ Q & \xrightarrow{\sim} & i^\perp \circ^* i^\perp \end{array}$$

(the oblique arrows are defined by the adjunction properties).

Similarly, there is an isomorphism ${}^*Q^\perp \circ Q^\perp \xrightarrow{\sim} i \circ i^*$ such that the following diagram is commutative:

$$\begin{array}{ccc} {}^*Q^\perp \circ Q^\perp & \xrightarrow{\sim} & i \circ i^* \\ & \searrow \quad \swarrow & \\ & \mathrm{id} & \end{array}$$

Finally, there is a functorial morphism of degree 1, $\partial : i^{\perp} \circ^* i^{\perp} \to i \circ i^*$, *such that the following triangle is distinguished* ($\deg \partial = 1$)*:*



Such a morphism δ *is unique and satisfies* $\delta(TX_0) = -T\delta(X)$ *(*X *an object* $q \circ q$, T *the translation).*

3 Derived categories of an abelian category

3.1 Derived categories

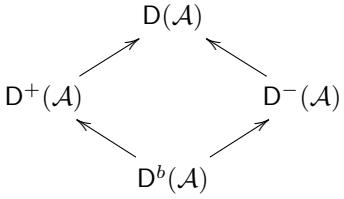
We use the notation of 1.2.3. We shall also use the following notation.

3.1.1 Notation

Let $\mathcal{A}$ be an abelian category. Set

$$\begin{aligned}
\mathsf{D}(\mathcal{A}) &= \mathsf{K}^{\infty,\infty}(\mathcal{A})/\mathsf{K}^{\infty,\varnothing}(\mathcal{A}) \\
\mathsf{D}^b(\mathcal{A}) &= \mathsf{K}^{b,b}(\mathcal{A})/\mathsf{K}^{b,\varnothing}(\mathcal{A}) \\
\mathsf{D}^+(\mathcal{A}) &= \mathsf{K}^{+,+}(\mathcal{A})/\mathsf{K}^{+,\varnothing}(\mathcal{A}) \\
\mathsf{D}^-(\mathcal{A}) &= \mathsf{K}^{-,-}(\mathcal{A})/\mathsf{K}^{-,\varnothing}(\mathcal{A}).
\end{aligned}$$

Proposition 3.1.2. *The natural functors appearing in the following diagram*



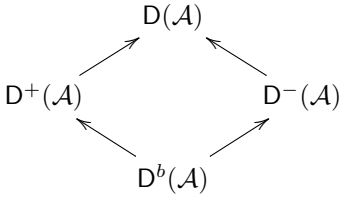
are fully faithful.

The natural functors

$$\begin{aligned}
\mathsf{D}^b(\mathcal{A}) = \mathsf{K}^{b,b}(\mathcal{A})/\mathsf{K}^{b,\varnothing}(\mathcal{A}) &\to \mathsf{K}^{+,b}(\mathcal{A})/\mathsf{K}^{+,\varnothing}(\mathcal{A}) \\
\mathsf{D}^b(\mathcal{A}) = \mathsf{K}^{b,b}(\mathcal{A})/\mathsf{K}^{b,\varnothing}(\mathcal{A}) &\to \mathsf{K}^{-,b}(\mathcal{A})/\mathsf{K}^{-,\varnothing}(\mathcal{A})
\end{aligned}$$

are equivalences of categories.

Since the functors in the diagram



are injective on objects, they realize the categories $\mathsf{D}^b(\mathcal{A})$, $\mathsf{D}^+(\mathcal{A})$, *and* $\mathsf{D}^-(\mathcal{A})$ *as full subcategories of* $\mathsf{D}(\mathcal{A})$.

The proof of this proposition is contained in Theorem 2.4.2.

Definition 3.1.3. *The category* $\mathsf{D}(\mathcal{A})$ *is called the* derived category *of* $\mathcal{A}$. *The objects of* $\mathsf{D}(\mathcal{A})$ *isomorphic to objects of* $\mathsf{D}^b(\mathcal{A})$ *are called the* bounded *objects of* $\mathsf{D}(\mathcal{A})$. *The objects of* $\mathsf{D}(\mathcal{A})$ *isomorphic to objects of* $\mathsf{D}^+(\mathcal{A})$ *are called the* left-bounded *objects, and the objects of* $\mathsf{D}(\mathcal{A})$ *isomorphic to objects of* $\mathsf{D}^-(\mathcal{A})$ *are called the* right-bounded *objects.*

Let D denote the canonical functor

$$D : \mathsf{C}(\mathcal{A}) \to \mathsf{D}(\mathcal{A}).$$

The "restriction" of D to the full subcategory $\mathcal{A}$ of $\mathsf{C}(\mathcal{A})$ will again be denoted by D. The functor D restricted to $\mathcal{A}$ is fully faithful. The functor D factors uniquely through $\mathsf{K}(\mathcal{A})$. Let X and Y be two objects of $\mathcal{A}$.

One readily checks that, for every $m \geqslant 0$, the groups

$$\hom_{\mathsf{D}(\mathcal{A})}(D(X), T^{-m}D(Y)) \qquad (T \text{ is the translation functor})$$

are zero. The cohomological dimension of $\mathcal{A}$ is the least integer n such that, for every $m > n$,

$$\hom_{\mathsf{D}(\mathcal{A})}(D(X), T^{m}D(Y)) = 0 \qquad \text{for every pair } X, Y \text{ of objects of } \mathcal{A}.$$

If there is no such integer, the cohomological dimension of $\mathcal{A}$ is said to be infinite.

Let $\mathsf{I}^+(\mathcal{A})$ (respectively $\mathsf{I}(\mathcal{A})$) denote the full triangulated subcategory of $\mathsf{K}^+(\mathcal{A})$ (respectively of $\mathsf{K}(\mathcal{A})$) defined by the complexes whose objects are injective in every degree.

Proposition 3.1.4. *Suppose that the category* $\mathcal{A}$ *has enough injectives. The natural functor*

$$Q^+ : \mathsf{K}^+(\mathcal{A}) \to \mathsf{D}^+(\mathcal{A})$$

induces an equivalence of categories

$$\mathsf{I}^+(\mathcal{A}) \to \mathsf{D}^+(\mathcal{A}).$$

The quasi-inverse functor is a right adjoint of Q^+.

If, in addition, $\mathcal{A}$ has finite cohomological dimension, the preceding assertion remains true after the superscripts + are omitted.

There is an analogous statement concerning projectives.

The proof of Proposition 3.1.4 relies on 2.6.4.

The triangulated structure of $\mathsf{D}(\mathcal{A})$ is made more explicit by the following proposition.

Let $\mathsf{E}(\mathcal{A})$ be the category of three-term exact sequences in $\mathsf{C}(\mathcal{A})$. The category $\mathsf{SSS}(\mathcal{A})$ of semi-split exact sequences (§1.2.4) is a full subcategory of $\mathsf{E}(\mathcal{A})$. We defined (loc. cit.) a functor

$$\rho : \mathsf{SSS}(\mathcal{A}) \to \mathsf{TrK}(\mathcal{A})$$

where $\mathsf{TrK}(\mathcal{A})$ denotes the category of distinguished triangles of $\mathsf{K}(\mathcal{A})$. This gives a functor

$$\sigma : \mathsf{SSS}(\mathcal{A}) \to \mathsf{TrD}(\mathcal{A})$$

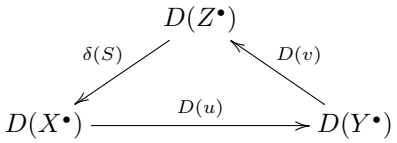
where $\mathsf{TrD}(\mathcal{A})$ denotes the category of distinguished triangles of $\mathsf{D}(\mathcal{A})$.

Proposition 3.1.5. *There exists a unique functor*

$$\Pi : \mathsf{E}(\mathcal{A}) \to \mathsf{TrD}(\mathcal{A})$$

of the following form ($\deg \delta(S) = 1$*):*

$$(S = 0 \to X^\bullet \to Y^\bullet \to Z^\bullet \to 0) \mapsto$$



whose restriction to $\mathsf{SSS}(\mathcal{A})$ *is* σ*.* This functor is essentially surjective.

Proposition 3.1.6. *The canonical cohomological functor*

$$\mathrm{H}^0 : \mathsf{K}(\mathcal{A}) \to \mathcal{A}$$

factors uniquely through a functor that we again denote by H^0*,*

$$\mathrm{H}^0 : \mathsf{D}(\mathcal{A}) \to \mathcal{A}.$$

On $\mathsf{D}(\mathcal{A})$*, the functor* H^0 *and its translates* H^i *form a conservative system; that is, a morphism* $f : X^\bullet \to Y^\bullet$ *is an isomorphism if and only if, for every integer* i*,*

$$\mathrm{H}^i(f) : \mathrm{H}^i(X) \to \mathrm{H}^i(Y)$$

is an isomorphism.

Definition 3.1.7. *A morphism* $f : X^\bullet \to Y^\bullet$ *of* $\mathsf{C}(\mathcal{A})$ *(respectively of* $\mathsf{K}(\mathcal{A})$*) is called a* quasi-isomorphism *if, for every integer* i*,*

$$\mathrm{H}^i(f) : \mathrm{H}^i(X) \to \mathrm{H}^i(Y)$$

is an isomorphism.

By the preceding proposition, the quasi-isomorphisms are the morphisms that become isomorphisms in $\mathsf{D}(\mathcal{A})$.

Definition 3.1.8. *Let* σ *be a set of objects of* $\mathcal{A}$ *and let* $X^\bullet$ *be an object of* $\mathsf{C}(\mathcal{A})$ *(respectively* $\mathsf{K}(\mathcal{A})$*). A right (respectively left) resolution of type* σ *of* $X^\bullet$ *is a quasi-isomorphism* $X^\bullet \to V^\bullet$ *(respectively* $V^\bullet \to X^\bullet$*), where* $V^\bullet$ *is a complex all of whose objects belong to* σ*. We say* injective resolution *(respectively projective resolution) instead of right (respectively left) resolution of injective (respectively projective) type.*

In general, we shall omit the words "right" or "left" when no ambiguity can result.

Proposition 3.1.9. *1. Suppose that every object of* $\mathcal{A}$ *embeds in an object of* σ *(respectively is a quotient of an object of* σ*). Then every object of* $\mathsf{C}^+(\mathcal{A})$ *(respectively* $\mathsf{C}^-(\mathcal{A})$*) has a right (respectively left) resolution of type* σ *in* $\mathsf{C}^+(\mathcal{A})$ *(respectively in* $\mathsf{C}^-(\mathcal{A})$*).*

2. Suppose, in addition, that there exists an integer n *such that for every exact sequence*

$$Y^0 \to Y^1 \to \cdots \to Y^{n-1} \to Y^n \to 0$$

$$\text{(respectively } 0 \to Y^n \to Y^{n-1} \to \cdots \to Y^1 \to Y^0\text{)}$$

of objects of $\mathcal{A}$ *in which, for every* i*,* $0 \leqslant i \leqslant n-1$*,* Y^i *is an object of* σ*, the object* Y^n *is also an object of* σ*. Then every object of* $\mathsf{C}(\mathcal{A})$ *has a right (respectively left) resolution of type* σ*.*

3.2 Study of Ext

Let $X^\bullet$ and $Y^\bullet$ be two objects of $\mathsf{C}(\mathcal{A})$ (respectively $\mathsf{K}(\mathcal{A})$), and let $D : \mathsf{C}(\mathcal{A}) \to \mathsf{D}(\mathcal{A})$ (respectively $Q : \mathsf{K}(\mathcal{A}) \to \mathsf{D}(\mathcal{A})$) be the canonical functor.

Definition 3.2.1. *We call the* ith hyper-Ext*, and denote by*

$$(X^\bullet, Y^\bullet) \mapsto \mathrm{Ext}^i(X^\bullet, Y^\bullet)$$

the functor $\hom_{\mathsf{D}(\mathcal{A})}(D(X^\bullet), T^i D(Y^\bullet))$ *(respectively* $\hom_{\mathsf{D}(\mathcal{A})}(Q(X^\bullet), T^i Q(Y^\bullet))$*).*

Proposition 3.2.2. *Let* $0 \to X^\bullet \to Y^\bullet \to Z^\bullet \to 0$ *be an exact sequence in* $\mathsf{C}(\mathcal{A})$*, and let* $V^\bullet$ *be an object of* $\mathsf{C}(\mathcal{A})$*. There are unbounded exact sequences*

$$\cdots \longrightarrow \mathrm{Ext}^i(V^\bullet, X^\bullet) \longrightarrow \mathrm{Ext}^i(V^\bullet, Y^\bullet) \longrightarrow \mathrm{Ext}^i(V^\bullet, Z^\bullet) \xrightarrow{\delta} \mathrm{Ext}^{i+1}(V^\bullet, X^\bullet) \longrightarrow \cdots$$

$$\cdots \longrightarrow \mathrm{Ext}^i(Z^\bullet, V^\bullet) \longrightarrow \mathrm{Ext}^i(Y^\bullet, V^\bullet) \longrightarrow \mathrm{Ext}^i(X^\bullet, V^\bullet) \xrightarrow{\delta} \mathrm{Ext}^{i+1}(Z^\bullet, V^\bullet) \longrightarrow \cdots$$

Let $X^\bullet$ and $Y^\bullet$ be two objects of $\mathsf{K}(\mathcal{A})$. Denote by $\mathsf{Qis}/X^\bullet$ (respectively $\mathsf{Qis}^+/X^\bullet$, $\mathsf{Qis}^-/X^\bullet$, $\mathsf{Qis}^b/X^\bullet$) the category of quasi-isomorphisms with target $X^\bullet$ and source in $\mathsf{K}(\mathcal{A})$ (respectively $\mathsf{K}^+(\mathcal{A})$, $\mathsf{K}^-(\mathcal{A})$, $\mathsf{K}^b(\mathcal{A})$). Similarly, define the categories $Y^\bullet/\mathsf{Qis}$, $Y^\bullet/\mathsf{Qis}^+$,... (quasi-isomorphisms with source $Y^\bullet$).

The following proposition summarizes the various equivalent definitions of Ext^i.

Proposition 3.2.3. *1. There are isomorphisms of functors*

$$\mathrm{Ext}^0(X^\bullet, Y^\bullet) = \hom_{\mathsf{D}(\mathcal{A})}(Q(X^\bullet), Q(Y^\bullet)) \xrightarrow{\sim} \varinjlim_{(\mathsf{Qis}/X^\bullet)^\circ} \hom_{\mathsf{K}(\mathcal{A})}(-, Y^\bullet) \xrightarrow{\sim}$$

$$\varinjlim_{Y^\bullet/\mathsf{Qis}} \hom_{\mathsf{K}(\mathcal{A})}(X^\bullet, -) \xrightarrow{\sim} \varinjlim_{(\mathsf{Qis}/X^\bullet)^\circ \times Y^\bullet/\mathsf{Qis}} \hom_{\mathsf{K}(\mathcal{A})}(-, -).$$

If $X^\bullet$ *is an object of* $\mathsf{K}^-(\mathcal{A})$*,*

$$\mathrm{Ext}^0(X^\bullet, Y^\bullet) \xrightarrow{\sim} \varinjlim_{(\mathsf{Qis}^-/X^\bullet)^\circ} \hom_{\mathsf{K}(\mathcal{A})}(-, Y^\bullet)$$

If $Y^\bullet$ *is an object of* $\mathsf{K}^+(\mathcal{A})$*,*

$$\mathrm{Ext}^0(X^\bullet, Y^\bullet) \xrightarrow{\sim} \varinjlim_{Y^\bullet/\mathsf{Qis}} \hom_{\mathsf{K}(\mathcal{A})}(X^\bullet, -)$$

If $X^\bullet$ *is an object of* $\mathsf{K}^-(\mathcal{A})$ *and* $Y^\bullet$ *is an object of* $\mathsf{K}^b(\mathcal{A})$*,*

$$\mathrm{Ext}^0(X^\bullet, Y^\bullet) \xrightarrow{\sim} \varinjlim_{Y^\bullet/\mathsf{Qis}^b} \hom_{\mathsf{K}(\mathcal{A})}(X^\bullet, -)$$

If $X^\bullet$ *is an object of* $\mathsf{K}^b(\mathcal{A})$ *and* $Y^\bullet$ *is an object of* $\mathsf{K}^+(\mathcal{A})$*,*

$$\mathrm{Ext}^0(X^\bullet, Y^\bullet) \xrightarrow{\sim} \varinjlim_{(\mathsf{Qis}^b/X^\bullet)^\circ} \hom_{\mathsf{K}(\mathcal{A})}(-, Y^\bullet)$$

If the category $\mathcal{A}$ has enough injectives and $Y^\bullet$ is an object of $\mathsf{K}^+(\mathcal{A})$, then $Y^\bullet$ has an injective resolution, unique up to isomorphism in $\mathsf{K}^+(\mathcal{A})$,

$$Y^\bullet \to I(Y^\bullet)$$

and

$$\mathrm{Ext}^0(X^\bullet, Y^\bullet) \xrightarrow{\sim} \mathrm{hom}_{\mathsf{K}(\mathcal{A})}(X^\bullet, I(Y^\bullet)).$$

There is an analogous statement for projectives. If the category $\mathcal{A}$ has enough injectives and if $\mathcal{A}$ has finite cohomological dimension*, then every object $Y^\bullet$ of $\mathsf{K}(\mathcal{A})$ has a unique injective resolution*

$$Y^\bullet \to I(Y^\bullet)$$

and

$$\mathrm{Ext}^0(X^\bullet, Y^\bullet) \xrightarrow{\sim} \mathrm{hom}_{\mathsf{K}(\mathcal{A})}(X^\bullet, I(Y^\bullet))$$

There is an analogous statement for projectives.

Remark: On making explicit the isomorphism of Proposition 3.2.3(3), one recovers the Yoneda definition.

4 Derived functors

4.1 Definition of derived functors

Definition 4.1.1. *Let $\mathcal{C}$ and $\mathcal{C}'$ be two graded categories (we denote by T the translation functor of $\mathcal{C}$ and $\mathcal{C}'$), and let F and G be two graded functors from $\mathcal{C}$ to $\mathcal{C}'$. A* morphism of graded functors *is a morphism of functors*

$$u : F \to G$$

having the following property:

For every object X of $\mathcal{C}$, the following diagram is commutative:

$$\begin{array}{ccc} F(TX) & \xrightarrow{u(TX)} & G(TX) \\ \uparrow \wr & & \uparrow \wr \\ TF(X) & \xrightarrow{Tu(X)} & TG(X) \end{array}$$

Let $\mathcal{C}$ and $\mathcal{C}'$ be two triangulated categories. Denote by $\mathsf{Fex}(\mathcal{C}, \mathcal{C}')$ the category of exact functors from $\mathcal{C}$ to $\mathcal{C}'$, the morphisms between two functors being morphisms of graded functors.

Let $\mathcal{A}$ and $\mathcal{B}$ be two abelian categories and let $\Phi : \mathsf{K}^*(\mathcal{A}) \to \mathsf{K}^{*'}(\mathcal{B})$ be an exact functor ($*$ and $*'$ denote one of the signs $+$, $-$, b, or v, "empty"). By composition, the canonical functor $Q : \mathsf{K}^*(\mathcal{A}) \to \mathsf{D}^*(\mathcal{A})$ gives a functor

$$\mathsf{Fex}(\mathsf{D}^*(\mathcal{A}), \mathsf{D}^{*'}(\mathcal{B})) \longrightarrow \mathsf{Fex}(\mathsf{K}^*(\mathcal{A}), \mathsf{D}^{*'}(\mathcal{B}))$$

and hence (also denoting by Q' the canonical functor $\mathsf{K}^{*'}(\mathcal{B}) \to \mathsf{D}^{*'}(\mathcal{B})$) a functor $\%$ (respectively $\%'$) $\mathsf{Fex}(\mathsf{D}^*(\mathcal{A}), \mathsf{D}^{*'}(\mathcal{B})) \to \mathsf{Ab}$:

$$\Psi \mapsto \mathrm{hom}(Q' \circ \Phi, \Psi \circ Q)$$
$$(\text{respectively } \Psi \mapsto \mathrm{hom}(\Psi \circ Q, Q' \circ \Phi) \ ).$$

Definition 4.1.2. *We say that* Φ *admits a* total right derived functor *(respectively total left derived functor) if the functor* $\%$ *(respectively* $\%'$*) is representable. An object representing* $\%$ *(respectively* $\%'$*) is called the total right (respectively left) derived functor of* Φ *and is denoted by* $\mathsf{R}\Phi$ *(respectively* $\mathsf{L}\Phi$*).*[§]

4.1.3 Notation

Let $\mathcal{A}$ and $\mathcal{B}$ be two abelian categories and let $f : \mathcal{A} \to \mathcal{B}$ be an additive functor. The *total right derived functor* of $\mathsf{K}^+(f) : \mathsf{K}^+(\mathcal{A}) \to \mathsf{K}^+(\mathcal{B})$ is denoted by R^+f. The functors R^-f, $\mathsf{R}f$, L^+f, L^-f, and $\mathsf{L}f$ are defined similarly.

Likewise, let $F : \mathsf{K}^*(\mathcal{A}) \to \mathcal{B}$ be a cohomological functor. By composition, the canonical quotient functor $Q : \mathsf{K}^*(\mathcal{A}) \to \mathsf{D}^*(\mathcal{A})$ defines a functor

$$\mathsf{Foco}(\mathsf{D}^*(\mathcal{A}), \mathcal{B}) \longrightarrow \mathsf{Foco}(\mathsf{K}^*(\mathcal{A}), \mathcal{B})$$

(where $\mathsf{Foco}(-,-)$ denotes the category of cohomological functors), and hence a functor $\%$ (respectively $\%'$) $\mathsf{Foco}(\mathsf{D}^*(\mathcal{A}), \mathcal{B}) \to \mathsf{Ab}$ given by $G \mapsto \hom(F, G \circ Q)$ (respectively $G \mapsto \hom(G \circ Q, F)$).

Definition 4.1.4. *We say that the functor* F *admits a* right cohomological derived functor *(respectively left cohomological derived functor) if the functor* $\%$ *(respectively* $\%'$*) is representable. An object representing* $\%$ *(respectively* $\%'$*) is called the right (respectively left) cohomological derived functor and is denoted by* $\mathsf{R}F$ *(respectively* $\mathsf{L}F$*).*

4.1.5 Notation

Let $\mathcal{A}$ and $\mathcal{B}$ be two abelian categories and let $f : \mathcal{A} \to \mathcal{B}$ be an additive functor. The right cohomological derived functor of

$$\mathrm{H}^0 \circ \mathsf{K}^+f : \mathsf{K}^+(\mathcal{A}) \to \mathcal{B}$$

is denoted by R^+f. When no confusion can result, the functor $\mathsf{R}^+f \circ T^i$ (T is the translation functor) is denoted by R^if. The right cohomological derived functor of $\mathrm{H} \circ \mathsf{K}f$ is denoted by $\mathsf{R}f$. When no confusion can result, the functor $\mathsf{R}f \circ T^i$ is denoted by R^if.

The functors L^-f, $\mathsf{L}f$, and L^if are defined similarly.

4.1.6 Remarks

As we shall see in the next subsection, these definitions include the classical definition of derived functors when the categories have enough injectives or projectives and the complexes are suitably bounded. They are nevertheless more general, but without further hypotheses they are not very manageable. For example, let $f : \mathcal{A} \to \mathcal{B}$ be an additive functor between two abelian categories. Suppose that the functors R^+f and $\mathsf{R}f$ exist. I do not know how to prove that $\mathsf{R}f$ induces on $\mathsf{D}^+(\mathcal{A})$ the functor R^+f. Suppose, in addition, that the functor R^+f (cohomological derived) exists. I do not know how to prove that the functor $\mathrm{H}^0 \circ \mathsf{R}^+f$ is isomorphic to R^+f. In practice, however, these properties will hold.

4.2 Existence of derived functors

Proposition 4.2.1. *The hypotheses are those of Definition 4.1.4. Suppose, in addition, that* $\mathcal{A}$ *is a* $\mathscr{U}$*-category, where* $\mathscr{U}$ *is a universe such that the set* $\mathbb{Z}$ *of rational integers belongs to* $\mathscr{U}$*, and such that the set of objects of* $\mathcal{A}$ *belongs to* $\mathscr{U}$*. Suppose also that* $\mathcal{B}$ *is the category of abelian* $\mathscr{U}$*-groups, or more*

[§]A more manageable definition (and one equivalent in practice) is given in [2, XVII 1.2].

generally the category of sheaves of abelian $\mathscr{U}$-groups on an arbitrary $\mathscr{U}$-site. (A $\mathscr{U}$-site is a $\mathscr{U}$-category whose set of objects belongs to $\mathscr{U}$, equipped with a topology.) The functor F admits a right cohomological derived functor. This functor is calculated as follows:

Let X be an object of $\mathsf{D}^*(\mathcal{A})$, and let $\underline{X}$ be the object of $\mathsf{K}^*(\mathcal{A})$ above X. There is a functorial isomorphism

$$\mathsf{R}F(X) = \varinjlim_{\underline{X}/\mathsf{Qis}^*} F(-).$$

In particular, let $f : \mathcal{A} \to \mathcal{B}$ be an additive functor. The functors $\mathsf{R}f$ and R^+f exist and are calculated as above. The functor $\mathsf{R}f$ induces on $\mathsf{D}^+(\mathcal{A})$ the functor R^+f. Since no confusion can then result, we shall use the notation $\mathsf{R}^i f$.

4.2.2 Remarks

Proposition 4.2.1 can be expressed in a more general form in the setting of triangulated categories. The hypotheses on the category $\mathcal{B}$ needed to ensure the validity of Proposition 4.2.1 are hypotheses asserting the existence and exactness of direct limits over pseudo-filtered $\mathscr{U}$-categories whose sets of objects belong to $\mathscr{U}$. Proposition 4.2.1 introduces an asymmetry between right and left derived functors, at least in practice.

Theorem 4.2.3. *The data are those of Definition 4.1.2. Suppose, in addition, that a full triangulated subcategory of $\mathsf{K}^*(\mathcal{A})$, denoted $\mathcal{C}$, is given, and denote by $\mathcal{N}$ the full triangulated subcategory of the acyclic objects of $\mathcal{C}$. Suppose that*

(1) Every object of $\mathcal{N}$ is taken by Φ to an acyclic object of $\mathsf{K}^{*'}(\mathcal{B})$.

(2) Every object X of $\mathsf{K}^*(\mathcal{A})$ is the source (respectively target) of a quasi-isomorphism whose target (respectively source) is an object of $\mathcal{C}$.

a) Then Φ admits a total right (respectively left) derived functor.

b) The functor $\mathsf{R}\Phi$ (respectively $\mathsf{L}\Phi$) is obtained as follows:

The restriction of the functor $Q' \circ \Phi : \mathsf{K}^*(\mathcal{A}) \to \mathsf{D}^{*'}(\mathcal{B})$ to $\mathcal{C}$ vanishes on the objects of $\mathcal{N}$ and therefore factors through $\mathcal{C}/\mathcal{N}$. This gives a functor $\Phi' : \mathcal{C}/\mathcal{N} \to \mathsf{D}^{*'}(\mathcal{B})$. But the natural functor $\mathcal{C}/\mathcal{N} \to \mathsf{D}^*(\mathcal{A})$ is an equivalence of categories (Theorem 2.4.2). Composing with its quasi-inverse gives the functor $\mathsf{R}\Phi$ (respectively $\mathsf{L}\Phi$).

c) Let X be an object of $\mathsf{K}^*(\mathcal{A})$, let Y be an object of $\mathcal{C}$, and let $X \to Y$ (respectively $Y \to X$) be a quasi-isomorphism. The object $\mathsf{R}\Phi \circ Q(X)$ (respectively $\mathsf{L}\Phi \circ Q(X)$) is isomorphic to $Q \circ \Phi(Y)$.

d) The functor $X \mapsto \mathsf{R}\Phi \circ Q(X)$ (respectively $X \mapsto \mathsf{L}\Phi \circ Q(X)$) is isomorphic to the functor $X \mapsto \varinjlim_{X/\mathsf{Qis}^*} Q \circ \Phi(-)$ (respectively $X \mapsto \varinjlim_{\mathsf{Qis}^*/X} Q \circ \Phi(-)$).

e) The functor $\mathrm{H}^0 \circ \Phi : \mathsf{K}^*(\mathcal{A}) \to \mathcal{B}$ admits a right (respectively left) cohomological derived functor, which is precisely $\mathrm{H}^0 \circ \mathsf{R}\Phi$ (respectively $\mathrm{H}^0 \circ \mathsf{L}\Phi$).

Corollary 4.2.4. *Suppose that $* = +$ (respectively $* = -$) in the hypotheses of the preceding theorem and that $\mathcal{A}$ has enough injectives (respectively projectives). Then Theorem 4.2.3 applies with $\mathcal{C}$ the category of complexes of injectives (respectively projectives). Suppose in addition that $\mathcal{A}$ has finite cohomological dimension. Then the theorem applies without restriction on $*$, with $\mathcal{C}$ the category of complexes of injectives (respectively projectives).*

Definition 4.2.5. *Let $\mathcal{A}$ and $\mathcal{B}$ be two abelian categories and let $f : \mathcal{A} \to \mathcal{B}$ be an additive functor.*

We say that f has finite cohomological dimension *on the right (respectively left) if R^+f (respectively L^-f) exists and there is an integer $m \geqslant 0$ such that, for every integer $n > m$, R^nf (respectively $\mathsf{L}^{-n}f$) is zero on the objects arising from $\mathcal{A}$ under the functor D. The* cohomological dimension *on the right (respectively left) of f is then the least integer m having this property. If R^+f (respectively L^-f) exists and f does not have finite cohomological dimension, we say that f has infinite cohomological dimension.*

An object X of $\mathcal{A}$ is said to be f-acyclic *on the right (respectively on the left) if, for every integer $n > 0$, $\mathsf{R}^nf(D(X)) = 0$ (respectively $\mathsf{L}^{-n}f(D(X)) = 0$).*

Corollary 4.2.6. *The data are those of Definition 4.2.5. Suppose there exists a set σ of objects of $\mathcal{A}$, stable under direct sums, having the following properties:*

1. *Every acyclic complex $\in \mathrm{Ob}\,\mathsf{K}^+(\mathcal{A})$ (respectively $\in \mathrm{Ob}\,\mathsf{K}^-(\mathcal{A})$) of objects of σ is taken by f to an acyclic complex.*
2. *Every object X of $\mathcal{A}$ embeds in (respectively is a quotient of) an object of σ. The hypotheses of Theorem 2.4.3 hold with $* = +$ (respectively $* = -$) and with $\mathcal{C}$ the category of complexes whose objects in every degree belong to σ. The elements of σ are right (respectively left) f-acyclic objects.*

If, in addition, f has finite right (respectively left) cohomological dimension, the set of right (respectively left) f-acyclic objects has, in addition to properties (1) and (2) above, property (2) of Proposition 3.1.9. Theorem 4.2.3 then applies to the functor $\mathsf{K}f$, with $\mathcal{C}$ the category of complexes whose objects are right (respectively left) f-acyclic in every degree. The functor $\mathsf{R}f$ (respectively $\mathsf{L}f$) exists and induces on $\mathsf{D}^+(\mathcal{A})$ the functor R^+f (respectively L^+f), and on $\mathsf{D}^-(\mathcal{A})$ the functor R^-f (respectively L^-f).

4.3 Product. Composition

Let $\mathcal{A}$ be an abelian category, let $F : \mathsf{D}(\mathcal{A}) \to \mathsf{Ab}$ be a cohomological functor, and let $X^\bullet$ and $Y^\bullet$ be two objects of $\mathsf{C}(\mathcal{A})$. The functor F defines a map

$$\mathrm{Ext}^0(X^\bullet, Y^\bullet) \to \mathrm{hom}_{\mathsf{Ab}}(F(D(X^\bullet)), F(D(Y^\bullet)))$$

and hence a pairing $F(D(X^\bullet)) \times \mathrm{Ext}^0(X^\bullet, Y^\bullet) \to F(D(Y^\bullet))$.

Applying translations to this pairing gives pairings

$$F^i(D(X^\bullet)) \times \mathrm{Ext}^j(X^\bullet, Y^\bullet) \to F^{i+j}(D(Y^\bullet)).$$

By definition, when these pairings are applied to cohomological derived functors, they are precisely the Yoneda products. The properties of these products follow immediately from this definition. We shall not develop them here.

Let $\mathcal{A}$, $\mathcal{A}'$, and $\mathcal{A}''$ be three abelian categories, and let $f : \mathcal{A} \to \mathcal{A}'$ and $g : \mathcal{A}' \to \mathcal{A}''$ be two additive functors. Suppose that the functors R^+f and R^+g exist. I do not know how to deduce that the functor $\mathsf{R}^+g \circ f$ exists, and even if the latter functor exists, the formula

$$\mathsf{R}^+g \circ f \xrightarrow{\sim} \mathsf{R}^+g \circ \mathsf{R}^+f$$

is probably not true in general. Nevertheless, one has the following proposition.

Proposition 4.3.1. *Suppose that the category $\mathcal{A}'$ has enough right g-acyclic objects and that $\mathcal{A}$ has enough right f-acyclic objects that f takes to right g-acyclic objects. Then the functor $\mathsf{R}^+g \circ f$ exists and there is an isomorphism*

$$\mathsf{R}^+g \circ f \xrightarrow{\sim} \mathsf{R}^+g \circ \mathsf{R}^+f.$$

There are analogous statements for left derived functors.

5 Examples

5.1 The functor $\mathsf{Rhom}^\bullet$

Let $\mathcal{A}$ be an abelian category with enough injectives.

The functor $Y \mapsto \hom^\bullet(X^\bullet, Y^\bullet)$ (1.3), where $X^\bullet$ is an object of $\mathsf{K}(\mathcal{A})$ and $Y^\bullet$ an object of $\mathsf{K}^+(\mathcal{A})$, has a total right derived functor (Corollary 4.2.4), denoted by $\mathsf{R}\hom^\bullet(X^\bullet, -)$. Let Y be an object of $\mathsf{D}^+(\mathcal{A})$. The functor

$$\begin{aligned} \mathsf{K}(\mathcal{A}) &\to \mathsf{D}(\mathsf{Ab}) \\ X^\bullet &\mapsto \mathsf{R}\hom^\bullet(X^\bullet, Y) \end{aligned}$$

is exact and vanishes on acyclic complexes, hence gives an exact bifunctor

$$\mathsf{D}(\mathcal{A})^\circ \times \mathsf{D}^+(\mathcal{A}) \longrightarrow \mathsf{D}(\mathsf{Ab})$$

which we denote by $\mathsf{Rhom}^\bullet$.

When $\mathcal{A}$ has finite cohomological dimension, the functor $\mathsf{Rhom}^\bullet$ extends to $\mathsf{D}(\mathcal{A})^\circ \times \mathsf{D}(\mathcal{A})$ (loc. cit.).

If, in addition, $\mathcal{A}$ has enough projectives, the functor hom can be derived with respect to the first argument. The two definitions coincide on their common domain of validity.

5.2 $\mathscr{T}or$ of sheaves

Let E be a ringed site (in particular, a ringed topological space), let $\mathscr{A}$ be its sheaf of rings, and let $\mathsf{Mod}(E)$ be the category of $\mathscr{A}$-modules. An object X of $\mathsf{Mod}(E)$ is said to be *$\mathscr{A}$-flat* if, for every exact sequence

$$0 \longrightarrow Y' \longrightarrow Y \longrightarrow Y'' \longrightarrow 0$$

the sequence $0 \to Y' \otimes_{\mathscr{A}} X \to Y \otimes_{\mathscr{A}} X \to Y'' \otimes_{\mathscr{A}} X \to 0$ is exact. There are enough $\mathscr{A}$-flat objects: the direct sums of objects $\mathscr{A}_U$, where U is an object of E and $\mathscr{A}_U$ is the sheaf $\mathscr{A}$ "extended by zero outside U." Thus Theorem 4.2.3 applies, and one can define the functor

$$\begin{aligned} \mathsf{D}^-(E, \mathscr{A}) \times \mathsf{D}^-(E, \mathscr{A}) &\to \mathsf{D}^-(E, \mathscr{A}) \\ (X, Y) &\mapsto X \overset{\mathsf{L}}{\otimes} Y \end{aligned}$$

the total tensor product, which is the left derived functor of the tensor product. Passing to cohomology defines the $\mathscr{T}or_i^{\mathscr{A}}(X, Y)$, the local hyper-Tor groups.

Since the category $\mathsf{Mod}(E)$ has enough injectives, one can derive the functor $\hom^\bullet(X, Y)$, the complex of local homomorphisms, and thus obtain $\mathsf{Rhom}(X, Y)$ ($X \in \mathsf{D}$, $Y \in \mathsf{D}^+$).

Let X and Y be two objects of $\mathsf{D}^-(E, \mathscr{A})$ and let Z be an object of $\mathsf{D}^+(E, \mathscr{A})$. There is a functorial isomorphism

$$\hom_{\mathsf{D}(E,\mathscr{A})}(X \overset{\mathsf{L}}{\otimes} Y, Z) \xrightarrow{\sim} \hom_{\mathsf{D}(E,\mathscr{A})}(X, \mathsf{Rhom}(Y, Z)).$$

5.3 Left derived functor of the inverse image

Let $f : E \to E'$ be a map of ringed topological spaces. The inverse-image functor

$$f^* : \mathsf{Mod}(E') \to \mathsf{Mod}(E)$$

is not necessarily exact. But one knows how to define f^*-flat objects, and there are enough such objects. Thus one can define the functor $\mathsf{L}^- f^*$. There is likewise a duality formula:

Let X be an object of $\mathsf{D}^-(E, \mathscr{A})$ and let Y be an object of $\mathsf{D}^+(E', \mathscr{A}')$. There is a functorial isomorphism

$$\hom_{\mathsf{D}(E',\mathscr{A}')}(\mathsf{L}^- f^*(X), Y) \xrightarrow{\sim} \hom_{\mathsf{D}(E,\mathscr{A})}(X, \mathsf{R}^+ f_*(Y)).$$

SGA 5 — Exposé I

Dualizing Complexes

by A. Grothendieck
(written up by L. Illusie)

Introduction

This exposé is devoted to the biduality theorem in étale cohomology. The theory developed here and in SGA A XVIII (SGA A = SGA 4), for the étale topology and constructible torsion sheaves on preschemes, is formally very analogous to the one developed in HARTSHORNE [H] for the Zariski topology and coherent sheaves: the latter served, to a very large extent, as its model. But, whereas in the case of "continuous" coefficients the existence of dualizing complexes presents no difficulties, in the case of "discrete" coefficients, on the other hand, it is much more delicate to prove, and it seems to require resolution of singularities in an essential way. See however Deligne's biduality theorem (SGA $4^{1/2}$, Finiteness Theorem 4.3.).

Paragraph 1 contains the definition of dualizing complexes and the formal properties that follow from it, notably the interpretation of dualizing functors as "exchangers of functors."

In paragraph 2, one shows that, on a connected locally noetherian prescheme, a dualizing complex is determined uniquely, up to a translation of degrees and tensoring by an invertible sheaf.

In paragraph 3, one comes to the central theorem of the exposé (3.4.1.), which asserts that, on a "good" regular prescheme X, for example on an excellent noetherian regular prescheme of characteristic zero[1], the complex $(\mathbb{Z}/n\mathbb{Z})_X$ is dualizing.

Paragraph 4 gives the applications of the theory to the local duality theorem. The latter expresses that, on a "good" prescheme X endowed with a closed point x whose residue field is separably closed, and for a constructible sheaf F, one has a perfect pairing between $\underline{\mathrm{H}}^i(F')_x$ and $\underline{\mathrm{H}}^{-i}_x(F)$, where F' is the dual of F, i.e. $F' = \mathrm{R}\,\underline{\underline{\mathrm{Hom}}}(F, K_X)$, where K_X is a dualizing complex.

Finally, in paragraph 5, one proves directly that on a regular prescheme of dimension 1 the complex $(\mathbb{Z}/n\mathbb{Z})_X$ is dualizing (n prime to the residual characteristics).

1 Definition and formal properties of dualizing complexes

We fix a coefficient ring $A = \mathbb{Z}/n\mathbb{Z}$. If X is a prescheme, we denote by A_X the constant sheaf on $X_{\text{ét}}$ with value A, and by $\mathrm{D}(X)$ the derived category of the category of A_X-modules. We denote, on the other hand, by $\mathrm{D}_c(X)$ the full triangulated subcategory of $\mathrm{D}(X)$ formed by the complexes F such that $\mathrm{H}^i(F)$ is a constructible A_X-module for every i. We put $\mathrm{D}^*_c(X) = \mathrm{D}^*(X) \cap \mathrm{D}_c(X)$, where $* = \varnothing$, $+$, $-$, or b.

[1] This last restriction will become unnecessary once one has resolution of singularities à la Hironaka for these preschemes, and the "purity theorem."

Definition 1.1

An A_X-module I is said to be *quasi-injective* if one has

$$\underline{\mathrm{Ext}}^i(F, I) = 0$$

for every *constructible* A_X-module F and every $i > 0$.

Remarks 1.2

a) Contrary to what happens in the case of "continuous" coefficients (cf. [H] II.7.17), a quasi-injective sheaf is not injective in general. For example, let $X = \mathrm{Spec(R)}$ and $A = \mathbb{Z}/2\mathbb{Z}$: the sheaf A_X is quasi-injective, but is not injective, nor even of finite injective dimension, since $\mathrm{H}^*(X; A_X) = \mathrm{H}^*(\mathbb{Z}/2\mathbb{Z}; \mathbb{Z}/2\mathbb{Z})$ is a polynomial algebra on one generator of dimension 1.

b) Let I be a quasi-injective A_X-module. It is false in general that the relation $\underline{\mathrm{Ext}}^i(F, I) = 0$ for $i > 0$, valid for constructible F, is valid for every F. Indeed, take $A = \mathbb{F}_\ell$. Let k be a field, $\overline{k}$ a separable closure of k, and $f : \overline{x} = \mathrm{Spec}(\overline{k}) \to X = \mathrm{Spec}(k)$ the canonical morphism, and suppose that, for every connected étale covering $X' \to X$, there exists a connected étale covering $X'' \to X'$ such that $[X'' : X']$ is divisible by ℓ (take, for example, $k = \mathbb{Q}$). Consider the exact sequence

$$(*) \qquad 0 \longrightarrow A_X \xrightarrow{\varepsilon} f_* f^* A_X \longrightarrow F \longrightarrow 0$$

defined by the adjunction arrow ε. In view of the hypothesis, the section of $\underline{\mathrm{Ext}}^1(F, A_X)$ defined by $(*)$ does not vanish above any U étale over X; hence $\underline{\mathrm{Ext}}^1(F, A_X)_{\overline{x}} \neq 0$. But one checks trivially that A_X is quasi-injective.

Proposition 1.3 (cf. [H] 1.7.6)

Let X be a prescheme and $N \in \mathbb{Z}$. The following conditions on $K \in \mathrm{ob\,D}^+(X)$ are equivalent:

(i) K is isomorphic, in $\mathrm{D}(X)$, to a bounded complex I such that I^i is quasi-injective for every i and zero for $i > N$;

(ii) for every $F \in \mathrm{ob\,D}^b_c(X)$ such that $\mathrm{H}^i(F) = 0$ for $i < 0$, one has $\underline{\mathrm{Ext}}^i(F, K) = 0$ for $i > N$;

(iii) for every constructible A_X-module F, one has $\underline{\mathrm{Ext}}^i(F, K) = 0$ for $i > N$.

Proof. $(i) \Rightarrow (ii)$. Let $F \in \mathrm{ob\,D}^b_c(X)$ be such that $\mathrm{H}^i(F) = 0$ for $i < 0$, and let $I \in \mathrm{ob\,D}^+(X)$ be bounded and such that I^i is quasi-injective for every i and zero for $i > N$; we show that $\underline{\mathrm{Ext}}^i(F, I) = 0$ for $i > N$. Arguing by induction on the number of indices i such that $I^i \neq 0$, one is reduced, by dévissage, to the case where $N = 0$ and I is concentrated in degree 0. One then has a biregular spectral sequence

$$\mathrm{E}_2^{pq} = \underline{\mathrm{Ext}}^p(\mathrm{H}^{-q}(F), I) \Rightarrow \underline{\mathrm{Ext}}^*(F, I).$$

Since I is quasi-injective, $\mathrm{E}_2^{pq} = 0$ for $p > 0$ and every q, and hence one has $\mathrm{E}_2^{0i} = \underline{\mathrm{Hom}}(\mathrm{H}^{-i}(F), I) \xrightarrow{\sim} \underline{\mathrm{Ext}}^i(F, I)$, which gives the conclusion.

$(ii) \Rightarrow (iii)$ is trivial.

$(iii) \Rightarrow (i)$ We may suppose that K is bounded below and has injective components. The hypothesis, applied to $F = A_X$, implies that $\mathrm{H}^i(K) = 0$ for $i > N$. We may therefore replace K by an isomorphic complex K', bounded, and such that K'^i is injective for $i < N$ and zero for $i > N$. It is then observed that K'^N is quasi-injective, which completes the proof.

Remark 1.3.1

The writer does not know whether (1.3) is still true when, in condition (ii), the hypothesis "$F \in \mathrm{ob}\,\mathrm{D}_c^b(X)$" is replaced by "$F \in \mathrm{ob}\,\mathrm{D}_c^+(X)$".

Definition 1.4

The *quasi-injective dimension* of K, denoted $\dim.q.inj(K)$, is the lower bound (in $\overline{\mathrm{R}}$) of the integers N satisfying the equivalent conditions of (1.3).

If K is of finite quasi-injective dimension, the functor $\mathrm{R}\,\underline{\mathrm{Hom}}(\quad, K) : \mathrm{D}(X) \to \mathrm{D}(X)$ induces a functor $\mathrm{D}_c^b(X) \to \mathrm{D}^b(X)$.

We shall see below that if X is smooth of dimension d over a field k and n is prime to the characteristic of k, then $\dim.q.inj(A_X) = 2d$.

The example of (1.2 a)) shows that a complex of finite quasi-injective dimension is not necessarily of finite injective dimension. Nevertheless one has:

Proposition 1.5

Let X be a locally noetherian prescheme and $K \in \mathrm{ob}\,\mathrm{D}^+(X)$. Suppose that there exists an integer N such that $\mathrm{cd}_{\mathbf{n}}(X) \leqslant N$, where $\mathbf{n}$ is the set of prime divisors of n (notation of SGAA X 1). Then, for $N' \in \mathbb{Z}$, one has

$$\dim.q.inj(K) \leqslant N' \quad \Longrightarrow \quad \dim.inj(K) \leqslant N + N'.$$

We shall use, in the proof, the following

Lemma 1.5.1

Let C be an abelian category satisfying (AB5) and possessing a family of generators $(U_i)_{i \in I}$. Let $K \in \mathrm{ob}\,\mathrm{D}^+(C)$ and $N \in \mathbb{Z}$. The following conditions are equivalent:

(i) $\dim.inj(K) \leqslant N$;

(ii) for every $i \in I$ and every quotient F of U_i, one has

$$\mathrm{Ext}^n(F, K) = 0 \qquad \text{for } n > N.$$

Proof. It suffices to prove $(ii) \Rightarrow (i)$. By a well-known argument (cf. for example [H] 1.7.6), one is reduced to showing that if $K' \in \mathrm{ob}(C)$ is such that $\mathrm{Ext}^1(F, K') = 0$ every time F is a quotient of a U_i, then K' is injective. In other words, one has to prove that, if every morphism from a subobject

V of a U_i into K' extends to U_i, then K' is injective. But this follows immediately from the proof of Lemma 1, p. 136 of (Tohoku).

Proof of (1.5). Suppose $\dim.q.inj(K) \leqslant N'$ and prove $\dim.inj(K) \leqslant N + N'$. Since the category of A_X-modules admits as generators the $A_{U,X}$ where U is étale of finite type over X, it suffices, by (1.5.1), to prove that $\mathrm{Ext}^i(X; F, K) = 0$ for $i > N + N'$ when F is a quotient of such an $A_{U,X}$, hence constructible (SGAA IX 2.9). Consider the spectral sequence

$$\mathrm{E}_2^{pq} = \mathrm{H}^p(X; \underline{\mathrm{Ext}}^q(F, K)) \Rightarrow \mathrm{Ext}^*(X; F, K).$$

The hypothesis $\mathrm{cd}_{\mathbf{n}}(X) \leqslant N$ (resp. $\dim.q.inj(K) \leqslant N'$) implies $\mathrm{E}_2^{pq} = 0$ for $p > N$ (resp. $q > N'$). Hence $\mathrm{E}_2^{pq} = 0$ for $p + q > N + N'$, whence the conclusion.

Remark 1.5.2

The hypothesis of (1.5) is verified (with $N = 2d$) if X is a prescheme of finite type and dimension d over a separably closed field k, with n prime to $\mathrm{char}(k)$ (SGAA X 4).

Proposition 1.6

Let $f : X \to Y$ be a separated quasi-finite morphism of noetherian preschemes, and let $K \in \mathrm{ob}\,\mathrm{D}^+(Y)$. Then, for $N \in \mathbb{Z}$, one has

$$\dim.q.inj(K) \leqslant N \quad \Longrightarrow \quad \dim.q.inj(\mathrm{R}^!f(K)) \leqslant N.$$

Proof. According to the "Main theorem" (EGA IV 8.12.6), there exists a factorization of f as $f = uf'$, where f' is an open immersion and u is a finite morphism. We have $\mathrm{R}^!f = \mathrm{R}^!f'\,\mathrm{R}^!u$, which reduces us to examining separately the case of an open immersion and that of a finite morphism. If f is an open immersion, the assertion is trivial (since every constructible sheaf on X is then induced by a constructible sheaf on Y). Suppose therefore that f is a finite morphism, and let F be a constructible A_X-module. We then have the duality isomorphisms (SGAA XVIII 3.1.9.6)

$$f_*\underline{\mathrm{Ext}}^i(F, \mathrm{R}^!f(K)) \xrightarrow{\sim} \underline{\mathrm{Ext}}^i(f_*F, K).$$

Since $f_*(F)$ is constructible (SGAA IX 2.14), it follows that, if $\dim.q.inj(K) \leqslant N$, then $f_*\underline{\mathrm{Ext}}^i(F, \mathrm{R}^!f(K)) = 0$ for $i > N$, hence $\underline{\mathrm{Ext}}^i(F, \mathrm{R}^!f(K)) = 0$ for $i > N$ (SGAA VIII 5.5), as required.

Let now X be a prescheme, and let $K \in \mathrm{ob}\,\mathrm{D}^+(X)$. Denote by $\underline{D}_K$ the functor $\mathrm{R}\,\underline{\mathrm{Hom}}(\ \ , K)$. We shall define, for $F \in \mathrm{ob}\,\mathrm{D}(X)$, a functorial homomorphism $F \to \underline{D}_K\underline{D}_K F$ (cf. [H] V.1.2). The construction which follows would be valid more generally on a ringed topos. We may first suppose that K is formed of injectives, which allows us to "remove the R". The identity morphism $\underline{\mathrm{Hom}}(F, K) \to \underline{\mathrm{Hom}}(F, K)$ defines, by the formula dear to Cartan, a homomorphism $F \otimes \underline{\mathrm{Hom}}(F, K) \to K$, whence, by a second application of the said formula, a homomorphism $F \to \underline{\mathrm{Hom}}(\underline{\mathrm{Hom}}(F, K), K)$, which is the announced homomorphism, and which we baptize the canonical homomorphism. We say that the pair (F, K) is *bidualizing*, or *satisfies biduality*, or again that F is *reflexive* relative to K, if the canonical homomorphism $F \to \underline{D}_K\underline{D}_K F$ is an isomorphism.

From now on, unless expressly mentioned otherwise, all preschemes considered will be assumed locally noetherian.

Definition 1.7

Let X be a prescheme. A complex $K \in \mathrm{ob}\,\mathrm{D}^+(X)$ is said to be *dualizing* if the following conditions are satisfied:

(i) K is of finite quasi-injective dimension;

(ii) for every $F \in \mathrm{ob}\,\mathrm{D}_c^-(X)$, one has $\underline{D}_K(F) \in \mathrm{ob}\,\mathrm{D}_c^+(X)$;

(iii) every $F \in \mathrm{ob}\,\mathrm{D}_c^b(X)$ is reflexive relative to K.

Remarks 1.8

a) By a standard dévissage (truncating F and using the fact that $\mathrm{D}_c(X)$ is triangulated), one sees that condition (ii) is equivalent to

(ii bis): for every constructible A_X-module F and every $i \in \mathbb{Z}$, $\underline{\mathrm{Ext}}^i(F, K)$ is constructible.

b) Condition (ii bis) implies $K \in \mathrm{ob}\,\mathrm{D}_c^+(X)$. Contrary to the example of coherent sheaves (EGA 0_{III} 12.3.3), the converse is perhaps not automatically verified. It is however verified (see no. 3) in the "good" cases, for example when one has on X resolution of singularities and purity (in particular if X is an excellent prescheme of characteristic zero).

c) By dévissage on F, one sees that condition (iii) is equivalent to (iii bis): every constructible A_X-module F is reflexive relative to K.

d) If $K \in \mathrm{ob}\,\mathrm{D}^+(X)$ satisfies (i) and (ii) (resp. is dualizing), the functor $\underline{D}_K$ induces a functor (resp. an equivalence of categories) $(\mathrm{D}_c^b(X))^\circ \to \mathrm{D}_c^b(X)$.

e) If $K \in \mathrm{ob}\,\mathrm{D}^+(X)$ is of finite *injective* dimension (cf. 1.5.2) and satisfies (ii), then, for every $F \in \mathrm{ob}\,\mathrm{D}_c(X)$, one has $\underline{D}_K(F) \in \mathrm{D}_c(X)$, and $\underline{D}_K$ induces a functor $(\mathrm{D}_c^+(X))^\circ \to \mathrm{D}_c^-(X)$.

If moreover K is dualizing, every $F \in \mathrm{ob}\,\mathrm{D}_c(X)$ is reflexive relative to K, and $\underline{D}_K$ induces equivalences of categories

$$(\mathrm{D}_c(X))^\circ \xrightarrow{\approx} \mathrm{D}_c(X), \quad (\mathrm{D}_c^-(X))^\circ \xrightarrow{\approx} \mathrm{D}_c^+(X), \quad (\mathrm{D}_c^+(X))^\circ \xrightarrow{\approx} \mathrm{D}_c^-(X).$$

It is not known whether this conclusion remains valid without the restriction that K be of finite injective dimension.

We now turn to the "exchange formulas." We shall not return to the notion of the tor-dimension of a complex, see SGA A, Exposé XVII, 4.1.9.[2] Retain only the following point: if X is a prescheme and $G \in \mathrm{ob}\,\mathrm{D}^-(X)$, the condition $\underline{\mathrm{Tor}}_i(F, G) = 0$ for $i \geqslant N$ and all A_X-modules F is equivalent to the same condition with F constructible, by SGA A, Exposé IX, 2.9 and the commutation of $\otimes^{\mathrm{L}}$ with filtered inductive limits. Thus there is no need to introduce a notion of "quasi-tor-dimension."

Lemma 1.9, cf. [H] II.4.3.

a) Let X be a prescheme, let $F \in \mathrm{ob}\,\mathrm{D}_c(X)$, and let $G \in \mathrm{ob}\,\mathrm{D}_c^-(X)$. One has $F \otimes^{\mathrm{L}} G \in \mathrm{ob}\,\mathrm{D}_c(X)$ if $F \in \mathrm{ob}\,\mathrm{D}_c^-(X)$, or if G has finite tor-dimension.

[2] See also SGA 6, I, 5.

b) Let $f : X \to Y$ be a morphism of preschemes and let $G \in \operatorname{ob} \mathrm{D}_c(Y)$. Then $f^*(G) \in \operatorname{ob} \mathrm{D}_c(X)$.

Proof. Part (b) follows trivially from SGA A, Exposé IX, 2.4. We prove (a). Either hypothesis on (F, G) implies that the spectral sequence

$$E_2^{pq} = \sum_{q_1+q_2=q} \underline{\mathrm{Tor}}_{-p}(\mathrm{H}^{q_1}(F), \mathrm{H}^{q_2}(G)) \Rightarrow \mathrm{H}^*(F \otimes^{\mathrm{L}} G)$$

is biregular. Hence one is reduced to the case where F and G are concentrated in degree 0, that is, are constructible A_X-modules. The question is local, so one may suppose X noetherian. Then F admits, by SGA A, Exposé IX, 2.7, a left resolution F' in which the F'^i are of the form $A_{U,X}$ with U étale and of finite type over X. We have

$$F \otimes^{\mathrm{L}} G \xleftarrow{\sim} F' \otimes G,$$

and the result follows since the $A_{U,X} \otimes G$ are constructible. □

Notation 1.10. If X is a prescheme, we denote by $\mathrm{D}^b(X)_{\mathrm{torf}}$, respectively $\mathrm{D}^b(X)_{\mathrm{qinjf}}$, the full subcategory of $\mathrm{D}(X)$ consisting of objects of finite tor-dimension, respectively of finite quasi-injective dimension.

Proposition 1.11, cf. [H] V.2.6. Let X be a prescheme and $K \in \operatorname{ob} \mathrm{D}^+(X)$.

a) For $F, G \in \operatorname{ob} \mathrm{D}^-(X)$, respectively for $F \in \operatorname{ob} \mathrm{D}(X)$ and $G \in \operatorname{ob} \mathrm{D}^b(X)_{\mathrm{torf}}$, there is a functorial isomorphism
$$\underline{D}_K(F \otimes^{\mathrm{L}} G) \xrightarrow{\sim} \mathrm{R}\,\underline{\mathrm{Hom}}(F, \underline{D}_K(G)).$$

b) If K satisfies conditions (i) and (ii) of Definition 1.7, then
$$G \in \operatorname{ob} \mathrm{D}_c^b(X)_{\mathrm{torf}} \Longrightarrow \underline{D}_K(G) \in \operatorname{ob} \mathrm{D}_c^b(X)_{\mathrm{qinjf}}$$
and $\underline{D}_K(G)$ satisfies condition 1.7(ii).

c) If K is dualizing, then for $F \in \operatorname{ob} \mathrm{D}_c^-(X)$ and $G \in \operatorname{ob} \mathrm{D}_c^b(X)$, respectively for $F \in \operatorname{ob} \mathrm{D}(X)$ and $G \in \operatorname{ob} \mathrm{D}_c^b(X)$ with $\underline{D}_K(G) \in \operatorname{ob} \mathrm{D}_c^b(X)_{\mathrm{torf}}$, there is a functorial isomorphism
$$\underline{D}_K(F \otimes^{\mathrm{L}} \underline{D}_K(G)) \xrightarrow{\sim} \mathrm{R}\,\underline{\mathrm{Hom}}(F, G).$$
Moreover,
$$\underline{D}_K(G) \in \operatorname{ob} \mathrm{D}_c^b(X)_{\mathrm{torf}} \Longrightarrow G \in \operatorname{ob} \mathrm{D}_c^b(X)_{\mathrm{qinjf}},$$
and G satisfies condition 1.7(ii).

d) If K is dualizing and has finite injective dimension, then the implications in (b) and (c) are equivalences.

Proof. Part (a) is precisely Cartan's adjunction formula, SGA 6, I, 7.4.

For (b), let $G \in \operatorname{ob} \mathrm{D}_c^b(X)_{\mathrm{torf}}$. If F is a variable constructible A_X-module, then the cohomology objects of $F \otimes^{\mathrm{L}} G$ are constructible, by Lemma 1.9, and vanish outside two fixed bounds independent

of F. The same therefore holds for the cohomology objects of $\underline{D}_K(F \otimes^{\mathrm{L}} G)$, and (a) gives the assertion.

For (c), the first assertion follows from (a) applied to $\underline{D}_K(G)$ in place of G, together with the reflexivity of G. The second follows by a similar argument to (b).

For (d), prove for instance the converse implication of (b). Suppose that $\underline{D}_K(G) \in \mathrm{ob}\,\mathrm{D}^b_c(X)_{\mathrm{qinjf}}$ and satisfies condition 1.7(ii). Then, as F varies through constructible modules, the cohomology objects of $\underline{D}_K(F \otimes^{\mathrm{L}} G)$ are constructible and vanish outside two fixed bounds. The same is consequently true for the cohomology objects of $\underline{D}_K\underline{D}_K(F \otimes^{\mathrm{L}} G)$; but

$$F \otimes^{\mathrm{L}} G \xrightarrow{\sim} \underline{D}_K\underline{D}_K(F \otimes^{\mathrm{L}} G)$$

because K is dualizing and of finite injective dimension, cf. 1.8(d). Hence G has finite tor-dimension. The converse implication in (c) is proved analogously. □

Remarks 1.11.1.

a) The editor does not know whether assertion (d) of Proposition 1.11 is valid under the sole hypothesis that K be dualizing.

b) One expresses the preceding proposition pictorially by saying that the dualizing functor $\underline{D}_K$ exchanges the functors $\otimes^{\mathrm{L}}$ and $\mathrm{R}\,\underline{\mathrm{Hom}}$, as well as the notions of finite tor-dimension and finite quasi-injective dimension. The exchange is, however, fully satisfactory only when K has finite injective dimension.

Proposition 1.12. Let Y be a noetherian prescheme, let $f : X \to Y$ be a morphism of finite type, and let $K \in \mathrm{ob}\,\mathrm{D}^+(Y)$. Suppose that n is prime to the residual characteristics of Y, and put

$$K_X = \mathrm{R}^! f(K_Y), \qquad \underline{D}_X = \underline{D}_{K_X}, \qquad \underline{D}_Y = \underline{D}_{K_Y},$$

in the notation of SGA A, Exposé XVIII, 3.1.

a) For $F \in \mathrm{ob}\,\mathrm{D}^-(X)$ there is a functorial isomorphism

$$\mathrm{R}f_*\underline{D}_X(F) \xrightarrow{\sim} \underline{D}_Y\mathrm{R}_!f(F). \tag{i}$$

If, moreover, K_X and K_Y are dualizing,[3] then for $F \in \mathrm{ob}\,\mathrm{D}^b_c(X)$ there is a functorial isomorphism

$$\mathrm{R}_!f\,\underline{D}_X(F) \xrightarrow{\sim} \underline{D}_Y\mathrm{R}f_*(F). \tag{ii}$$

b) For $F \in \mathrm{D}^-_c(Y)$ there is a functorial isomorphism[4]

$$\mathrm{R}^!f\,\underline{D}_Y(F) \xrightarrow{\sim} \underline{D}_Xf^*(F). \tag{i}$$

If, moreover, K_X and K_Y are dualizing, then for $F \in \mathrm{D}^b_c(Y)$ there is a functorial isomorphism

$$f^*\underline{D}_YF \xrightarrow{\sim} \underline{D}_X\mathrm{R}^!f\,F. \tag{ii}$$

[3] We shall see below that under fairly general conditions K_Y dualizing implies K_X dualizing.

[4] If the functor $\mathrm{R}^!f$ has finite cohomological dimension, as for example when Y is of finite type over a field (SGA A, Exposé X, 4.3 and Exposé XVIII, 3.1.7), the isomorphism (b)(i) is valid for $F \in \mathrm{ob}\,\mathrm{D}_c(Y)$.

Proof. The isomorphism (a)(i) is just the duality isomorphism of SGA A, Exposé XVIII, 3.1.9.6.

The isomorphism (a)(ii) is obtained by applying $\underline{D}_Y$ to both sides of (a)(i), written with argument $\underline{D}_X F$, and using the finiteness theorem SGA A, Exposé XVII, 5.3.6, which asserts that $\mathrm{R}_! f(\underline{D}_X(F)) \in \mathrm{ob}\,\mathrm{D}_c(Y)$.

The isomorphism (b)(i) is the induction formula of SGA A, Exposé XVIII, 3.1.12.2.

The isomorphism (b)(ii) is obtained by applying $\underline{D}_X$ to both sides of (b)(i), written with argument $\underline{D}_Y F$, and using 1.9(b). □

Scholium 1.12.1. In figurative language, the dualizing functors $\underline{D}_X$ and $\underline{D}_Y$ exchange the usual and unusual direct images, $\mathrm{R}f_*$ and $\mathrm{R}_! f$, and also the usual and unusual inverse images, f^* and $\mathrm{R}^! f$.

Corollary 1.13. Under the hypotheses of Proposition 1.12, suppose in addition that f is proper, and let $F \in \mathrm{ob}\,\mathrm{D}^-(X)$. If (F, K_X) is bidualizing, then $(\mathrm{R}f_* F, K_Y)$ is bidualizing. Conversely, if f is finite and $(\mathrm{R}f_* F, K_Y)$ is bidualizing, then (F, K_X) is bidualizing.

Proof. Suppose (F, K_X) is bidualizing. Applying $\mathrm{R}f_*$ to the canonical isomorphism $F \xrightarrow{\sim} \underline{D}_X^2 F$, one obtains[5]

$$\begin{aligned} \mathrm{R}f_* F &\xrightarrow{\sim} \mathrm{R}f_* \underline{D}_X \underline{D}_X F \\ &\xrightarrow{\sim} \underline{D}_Y \mathrm{R}f_* \underline{D}_X F \qquad \text{by (a)(i)} \\ &\xrightarrow{\sim} \underline{D}_Y \underline{D}_Y \mathrm{R}f_* F \qquad \text{by (a)(i).} \end{aligned}$$

The courageous reader will convince himself that the isomorphism obtained is the canonical one; this will prove the first assertion.

Now suppose f finite and $(f_* F, K_Y)$ bidualizing, since $\mathrm{R}f_* = f_*$ for f finite. We prove that the canonical morphism $F \to \underline{D}_X^2 F$ is an isomorphism. By Lemma 1.14(a) below, it suffices to show that the induced morphism

$$f_* F \longrightarrow f_* \underline{D}_X^2 F$$

is an isomorphism. But by applying (a)(i) twice, one convinces oneself that this morphism is precisely the canonical isomorphism

$$f_* F \longrightarrow \underline{D}_Y^2 f_* F,$$

which completes the proof. □

Lemma 1.14. Let $f : X \to Y$ be a finite morphism of preschemes.

a) For a morphism $u : F \to G$ in $\mathrm{D}(X)$, u is an isomorphism if and only if $f_* u$ is an isomorphism.

b) For $F \in \mathrm{ob}\,\mathrm{D}(X)$, one has $F \in \mathrm{ob}\,\mathrm{D}_c(X)$ if and only if $f_* F \in \mathrm{ob}\,\mathrm{D}_c(Y)$.

Proof. For (a), since f_* is exact, one may restrict to the case where F and G are concentrated in degree zero. The assertion then follows immediately from the computation of the fibres of $f_* F$ and $f_* G$, SGA A, Exposé VIII, 5.5.

[5] *Editorial note.* The printed source gives the intermediate term $\underline{D}_Y \mathrm{R}f_* \underline{D}_X F$ and cites Proposition 1.12(a)(i) for both successive arrows. This edition reproduces that chain. The mathematically coherent emendation is $\underline{D}_Y \mathrm{R}_! f\, \underline{D}_X F$ in the intermediate line, with Proposition 1.12(a)(ii) cited for the final arrow.

For (b), again one may restrict to the case where F is concentrated in degree zero. Necessity is known, SGA A, Exposé IX, 2.14. We prove sufficiency: f_*F constructible implies F constructible. The question is local upstairs, hence a fortiori downstairs, so we may suppose Y and hence X affine. By EGA IV, 17.16.6, there exists a finite family (Y_i) of affine subpreschemes of Y, pairwise disjoint and with union Y, such that, if $X_i = X \times_Y Y_i$, the induced morphism $f_i : X_i \to Y_i$ factors as

$$X_i \xrightarrow{u_i} X_i' \xrightarrow{v_i} Y_i,$$

where u_i is finite radicial and surjective and v_i is finite étale. Put $F|_{X_i} = F_i$. By the base-change theorem for finite morphisms, SGA A, Exposé VIII, 5.5, one has

$$f_{i*}(F_i) \xrightarrow{\sim} (f_*F)|_{Y_i},$$

and by SGA A, Exposé IX, 2.8, one is reduced to proving the assertion for (f_i, F_i). Put $F_i' = u_{i*}(F_i)$, so that $f_{i*}(F_i) = v_{i*}(F_i')$. It is clear from the definition of constructibility, respectively follows from SGA A, Exposé VIII, 1.1, that F_i, respectively F_i', is constructible if and only if F_i', respectively $v_{i*}(F_i')$, is constructible. This proves the claim. □

Corollary 1.15. Let $f : X \to Y$ be a separated quasi-finite morphism of noetherian preschemes. Let $K_Y \in \operatorname{ob} \mathrm{D}^+(Y)$, and put, as in Proposition 1.12,

$$K_X = \mathrm{R}^! f(K_Y), \qquad \underline{D}_X = \underline{D}_{K_X}, \qquad \underline{D}_Y = \underline{D}_{K_Y}.$$

If K_Y is dualizing, then K_X is dualizing.

Proof. We already know, by Proposition 1.6, that if K_Y has finite quasi-injective dimension, then the same is true of K_X. We show that if K_Y satisfies condition (ii), respectively condition (iii), of Definition 1.7, then K_X satisfies the same condition.

By the Main Theorem, EGA IV, 8.12.6, f factors as $f = f'i$, where i is an open immersion and f' is finite. Since

$$\mathrm{R}^! f \simeq \mathrm{R}^! i \, \mathrm{R}^! f',$$

one must treat separately the case of an open immersion and the case of a finite morphism. If f is an open immersion, the assertion is trivial, since a constructible sheaf on X is induced by a constructible sheaf on Y, and formation of $\mathrm{R}\,\underline{\mathrm{Hom}}$ commutes with restriction to an open.

Suppose then that f is finite. It follows from Corollary 1.13 that if K_Y satisfies (iii), then K_X satisfies (iii), taking account of the finiteness theorem SGA A, Exposé IX, 2.14. It remains to prove that if K_Y satisfies (ii), then K_X satisfies (ii). Let $F \in \operatorname{ob} \mathrm{D}_c^-(X)$. We must show that $\underline{D}_X(F) \in \operatorname{ob} \mathrm{D}_c^+(X)$. By the finiteness theorem, $f_*F \in \operatorname{ob} \mathrm{D}_c^-(Y)$. Hence, by the hypothesis on K_Y,

$$\underline{D}_Y f_*F \in \operatorname{ob} \mathrm{D}_c^+(Y).$$

But

$$\underline{D}_Y f_*F \xrightarrow{\sim} f_* \underline{D}_X(F)$$

by Proposition 1.12(a)(i), and Lemma 1.14(b) completes the proof. □

2. Uniqueness of the dualizing complex

In this section we suppose that A is local, that is,

$$A = \mathbb{Z}/\ell^{\nu}\mathbb{Z},$$

where ℓ is prime.

Theorem 2.1, cf. [H] V.3.1. Let X be a connected locally noetherian prescheme, and let K be a dualizing complex on X in the sense of Definition 1.7. Let also $K' \in \operatorname{ob} \mathrm{D}_c^+(X)$. Then K' is dualizing if and only if there exist an invertible A_X-module L and an integer r, necessarily determined up to unique isomorphism, such that

$$K' \xrightarrow{\sim} K \otimes^{\mathrm{L}} L[r].$$

Proof. Let L be an invertible A_X-module and r an integer, and put $L^{\vee} = \underline{\mathrm{Hom}}(L, A_X)$. For $F \in \operatorname{ob} \mathrm{D}(X)$ and $G \in \operatorname{ob} \mathrm{D}^+(X)$ there are canonical isomorphisms

$$\mathrm{R}\,\underline{\mathrm{Hom}}(F \otimes^{\mathrm{L}} L^{\vee}[-r], G) \xrightarrow{\sim} \mathrm{R}\,\underline{\mathrm{Hom}}(F, G \otimes^{\mathrm{L}} L[r]) \xrightarrow{\sim} \mathrm{R}\,\underline{\mathrm{Hom}}(F, G) \otimes^{\mathrm{L}} L[r]. \tag{$*$}$$

It follows immediately that, if $K' \simeq K \otimes^{\mathrm{L}} L[r]$, then K' is dualizing.

Moreover, if we write $\underline{D}_X = \underline{D}$ and $\underline{D}_{K'} = \underline{D}'$, then for $F \in \operatorname{ob} \mathrm{D}(X)$ the isomorphism $(*)$ gives

$$\underline{D}'F \xrightarrow{\sim} \underline{D}F \otimes^{\mathrm{L}} L[r].$$

Since $\underline{D}K \simeq A_X$, one obtains

$$\underline{D}'K \xrightarrow{\sim} L[r],$$

which shows that $L[r]$, hence L and r, are determined essentially uniquely by K'.

Conversely, suppose that K' is dualizing, and put

$$P = \underline{D}'K = \underline{D}'\underline{D}A_X = \mathrm{R}\,\underline{\mathrm{Hom}}(K, K').$$

We shall prove:

(a) $K' \xrightarrow{\sim} K \otimes^{\mathrm{L}} P$,

(b) $P \xrightarrow{\sim} L[r]$ for an invertible A_X-module L.

This will complete the proof of the theorem.

First observe that, by Proposition 1.9(b)(ii), for $F \in \operatorname{ob} \mathrm{D}_c(X)$ there is an isomorphism

$$F \otimes^{\mathrm{L}} P \xrightarrow{\sim} \underline{D}'\underline{D}F. \tag{$**$}$$

Applying $(**)$ to $F = K$ gives

$$K \otimes^{\mathrm{L}} P \xrightarrow{\sim} \underline{D}'\underline{D}K \xrightarrow{\sim} \underline{D}'A_X = K',$$

which proves (a).

Applying $(**)$ to

$$F = P' = \underline{D}\underline{D}'A_X$$

gives

$$P' \otimes^{\mathrm{L}} P = \underline{D'}\underline{DD}D'A_X \xrightarrow{\sim} \underline{D'}\underline{D'}A_X \xrightarrow{\sim} A_X.$$

Thus (b) follows from the following lemma. □

Lemma 2.2, cf. [H] V.3.3. Let X be a connected locally noetherian prescheme, and let $P, P' \in \operatorname{ob} \mathrm{D}_c^-(X)$ be such that

$$P \otimes^{\mathrm{L}} P' \xrightarrow{\sim} A_X.$$

Then there exist an invertible A_X-module L and an integer r such that

$$P \xrightarrow{\sim} L[r], \qquad P' \xrightarrow{\sim} L^\vee[-r].$$

Proof. The proof has two steps.

First suppose that $X = \operatorname{Spec}(k)$, with k separably closed. One merely repeats the easy proof given in [H]. The essential point is this: by EGA 0_{I}, 5.4.3, if M and M' are finite-type A-modules such that

$$M \otimes M' \xrightarrow{\sim} A,$$

then M and M' are invertible and $M' \simeq M^\vee$. This is where the hypothesis that A is local is used.

We now pass to the general case. By the special case just treated, for every $x \in X$ there exists an integer $r(x)$ such that

$$P_{\overline{x}} \simeq A_{\overline{x}}[r(x)], \qquad P'_{\overline{x}} \simeq A_{\overline{x}}[-r(x)].$$

Equivalently, $\underline{\mathrm{H}}^i(P_{\overline{x}}) = 0$, respectively $\underline{\mathrm{H}}^i(P'_{\overline{x}}) = 0$, except for $i = -r(x)$, respectively $i = r(x)$, and the corresponding nonzero cohomology modules are isomorphic to $A_{\overline{x}}$. It remains to show that the function $x \mapsto r(x)$ is locally constant.

Assume this for the moment. Since X is connected, r is constant, say equal to r_0. Then

$$\underline{\mathrm{H}}^i(P) = 0 \ (i \neq -r_0), \qquad \underline{\mathrm{H}}^i(P') = 0 \ (i \neq r_0),$$

and

$$\underline{\mathrm{H}}^{-r_0}(P) \otimes \underline{\mathrm{H}}^{r_0}(P') \xrightarrow{\sim} A.$$

Put $L = \underline{\mathrm{H}}^{-r_0}(P)$ and $L' = \underline{\mathrm{H}}^{r_0}(P')$. Let $u : \overline{x} \to \overline{y}$ be a specialization morphism, and let

$$u^* : L_{\overline{y}} \to L_{\overline{x}}, \qquad u'^* : L'_{\overline{y}} \to L'_{\overline{x}}$$

be the corresponding specialization morphisms. There is a commutative square

$$\begin{array}{ccc} L_{\overline{y}} \otimes L'_{\overline{y}} & \xrightarrow{\sim} & A_{\overline{y}} \\ {\scriptstyle u^* \otimes u'^*}\downarrow & & \downarrow \\ L_{\overline{x}} \otimes L'_{\overline{x}} & \xrightarrow{\sim} & A_{\overline{x}} \end{array} \qquad (*)$$

Choose a basis e, respectively f, of $L_{\overline{x}}$, respectively $L_{\overline{y}}$, and let e', respectively f', be the dual basis of $L'_{\overline{x}}$, respectively $L'_{\overline{y}}$, meaning that $e \otimes e'$ and $f \otimes f'$ map to 1. If $u^*(f) = \lambda e$ and $u'^*(f') = \lambda' e'$, the commutativity of $(*)$ gives $\lambda\lambda' = 1$. Hence u^* is an isomorphism, and u'^* is the contragredient

isomorphism. By SGA A, Exposé IX, 2.13, it follows that L and L' are locally constant, hence of finite presentation as A_X-modules. Consequently, for every $x \in X$ the canonical map

$$\underline{\mathrm{Hom}}(L, F)_{\overline{x}} \longrightarrow \mathrm{Hom}(L_{\overline{x}}, F_{\overline{x}})$$

is an isomorphism for every A_X-module F. Since the geometric fibres of L are invertible, L itself is invertible. Similarly L' is invertible, and $L' \simeq L^\vee$. Hence

$$P \simeq L[-r_0], \qquad P' \simeq L^\vee[r_0].$$

It remains only to prove that r is locally constant. For $m \in \mathbb{Z}$, the condition $r(x) = m$ is equivalent to

$$\underline{\mathrm{H}}^m(P')_{\overline{x}} \neq 0.$$

Thus, by SGA A, Exposé IX, 2.4, the function r is locally constructible. Therefore, to verify that it is locally constant, EGA IV, 1.10.1, allows one to suppose that X is local. Let x be its closed point and U the open complement.

We prove that r is constant. By induction on the dimension of X, we may already suppose that $r(y)$ is constant and equal to r_0 for $y \in U$; the point is to prove $r(x) = r_0$.

Assume the contrary, and derive a contradiction. By hypothesis

$$P|_U \xrightarrow{\sim} L[r_0]$$

with L an invertible A_U-module. After translating degrees we may suppose $r_0 = 0$. On the other hand $r(x) \neq 0$; write $r(x) = a > 0$. Let

$$i : U \to X, \qquad j : x \to X$$

be the canonical inclusions. Consider the exact sequence

$$0 \longrightarrow i_!(P|_U) \longrightarrow P \longrightarrow j_*j^*P \longrightarrow 0. \tag{$**$}$$

By hypothesis the only nonzero cohomology objects of P are $\underline{\mathrm{H}}^0(P)$ and $\underline{\mathrm{H}}^{-a}(P)$, and

$$\underline{\mathrm{H}}^0(P) \xrightarrow{\sim} i_!L.$$

It follows that $(**)$ splits naturally, via the map $P \to \underline{\mathrm{H}}^0(P)$, hence

$$P \xrightarrow{\sim} i_!(P|_U) \oplus j_*j^*P.$$

Therefore

$$\begin{aligned} P \otimes^{\mathrm{L}} P' &\xrightarrow{\sim} i_!(P|_U) \otimes^{\mathrm{L}} P' \oplus j_*j^*P \otimes^{\mathrm{L}} P' \\ &\xrightarrow{\sim} i_!(P|_U \otimes^{\mathrm{L}} P'|_U) \oplus j_*(j^*P \otimes^{\mathrm{L}} j^*P') \\ &\xrightarrow{\sim} i_!A_U \oplus j_*A_x, \end{aligned}$$

which is impossible, since $i_!A_U \oplus j_*A_x$ is plainly not isomorphic to A_X; already the sheaves $\underline{\mathrm{H}}^0$ are not isomorphic. This proves Lemma 2.2, and hence Theorem 2.1. □

3. Existence of dualizing complexes

3.1. Preliminaries

As was said in the introduction, the object of this section is to prove that, on a "good" regular prescheme X, the sheaf A_X is dualizing, where n is assumed prime to the residual characteristics.

In fact, one would like this to hold on excellent regular preschemes of equal characteristic; but there is no doubt that the proof given below will extend to them once resolution of singularities and the purity theorem are available in that case.

We first present the various ingredients which will be used.

3.1.1. Singular locus. Let X be a prescheme, locally noetherian. We shall say that X satisfies condition *(reg)* if the following equivalent properties hold (EGA IV, 6.12.3):

(i) for every sub-prescheme Y of X, the set $\mathrm{Reg}(Y)$ of regular points of Y is open in Y;

(ii) for every closed integral sub-prescheme Y of X, the set $\mathrm{Reg}(Y)$ contains a non-empty open subset of Y.

The condition (reg) is satisfied if X is locally of finite type over a complete noetherian local ring, for example over a field (EGA IV, 6.12.8), or over a Dedekind ring whose field of fractions has characteristic zero, for example over $\mathbb{Z}$ (EGA IV, 6.12.6); more generally, it is satisfied if X is excellent (EGA IV, 7.8.6).

3.1.2. Dévissage of constructible sheaves. Let X be a noetherian prescheme, and let C be a strictly full subcategory of the category $\mathrm{Cons}(X)$ of constructible A_X-modules. Suppose that C is stable under direct factors and extensions. The following conditions are equivalent:

(i) $C = \mathrm{Cons}(X)$;

(ii) C contains sheaves of the form $i_!(F)$, where $i : Y \to X$ is the immersion of an integral sub-prescheme and F is locally constant on Y;

(iii) C contains sheaves of the form $f_* i_!(A'_U)$, where $i : U \to Y$ is an open subset of an integral prescheme, $f : Y \to X$ is a finite morphism such that the generic point of Y is separable over its image, and $A' = \mathbb{Z}/\ell\mathbb{Z}$, for ℓ a prime divisor of n.

If X satisfies (reg) (3.1.1), these conditions are again equivalent to the following:

(i bis) the analogue of (ii), with Y moreover regular;

(ii bis) the analogue of (iii), with U regular.

If, in addition, X is affine, then in (ii), respectively in (ii bis), one may suppose Y closed in an open subset of the form $D(f)$, with $f \in \Gamma(X, \mathcal{O}_X)$.

Proof. The equivalence of (i)–(iii) was proved in SGA A, Exposé IX, 2.5 and 5.8. The remaining assertions follow by noetherian induction. □

3.1.3. Cohomological dimension. Let X be a locally noetherian prescheme. We denote by $(\mathrm{cdloc})_n$ the following condition. For every sub-prescheme Y of X, every geometric point $\overline{y}$ of Y, and every

$$f \in \Gamma(\widetilde{Y}(\overline{y}), \mathcal{O}_{Y,\overline{y}}),$$

where $\widetilde{Y}(\overline{y})$ denotes the strict localization of Y at $\overline{y}$ (SGA A, Exposé VIII, 7.1), one has

$$\mathrm{cd}_{\mathbf{n}}(\widetilde{Y}(\overline{y}) - V(f)) \leq \dim \mathcal{O}_{Y,\overline{y}} \quad (= \dim \mathcal{O}_{Y,y} \text{ by EGA IV, 6.1.3}),$$

where $\mathbf{n}$ is the set of prime divisors of n.

The condition $(\mathrm{cdloc})_n$ is satisfied if X is locally of finite type over a field (SGA A, Exposé XIV, 3.5), or is an excellent prescheme of characteristic zero (SGA A, Exposé XIX, 6.2).[6]

3.1.4. Absolute cohomological purity. Let X be a regular prescheme, and let Y be a regular closed sub-prescheme of X, of codimension d at every point. One says that the pair (X, Y) satisfies the absolute cohomological purity theorem, relative to n, if

$$\underline{\mathrm{H}}^i_Y(A_X) = 0 \qquad (i \neq 2d),$$

and if the "local fundamental class" homomorphism (SGA $4^{1/2}$, Cycle 2.2)

$$A_Y \longrightarrow \underline{\mathrm{H}}^{2d}_Y((\mu_n)^{\otimes d}_X)$$

is an isomorphism.

One says that the absolute cohomological purity theorem is true on X if every pair (U, Y) as above satisfies it, where U is an open subset of X.

Absolute purity is true on X if X is smooth over a perfect field of characteristic prime to n (SGA A, Exposé XVI, 3.9), or if X is an excellent prescheme of characteristic zero (SGA A, Exposé XIX, 3.2), or if X is regular of dimension 1 (cf. 5.1).[7]

3.1.5. Hironaka-style resolution of singularities.

a) Let X be a regular prescheme, and let $D \geq 0$ be a divisor on X. One says that D has *strict normal crossings* if there exists a finite family $(f_i)_{i \in I}$ of elements of $\Gamma(X, \mathcal{O}_X)$ such that

$$D = \sum_{i \in I} \mathrm{Div}(f_i)$$

(EGA IV, 21), and such that, for every $x \in \mathrm{Supp}(D)$, the germs $(f_i)_x$ which lie in $\mathfrak{m}_x$ form part of a regular system of parameters. One says that D has *normal crossings* if, locally for the étale topology, D has strict normal crossings.

The standard example of a normal crossings divisor is furnished by a locally finite union of coordinate hyperplanes in affine space.

b) Let X be a locally noetherian prescheme. We shall say that X is *strongly desingularizable* if the following condition is satisfied: for every finite morphism $f : Y \to X$, where Y is integral and its generic point is separable over its image, and every regular open subset U of Y, there exists a proper birational morphism $h : Y' \to Y$, with Y' regular, such that h induces an isomorphism from $U' = h^{-1}(U)$ onto U, and $Y' - U'$ is a normal crossings divisor.

[6] Added in 1977: or, by a recent result of G. Ofer, if X is excellent, regular, and of dimension 2.
[7] Added in 1977: or, by a recent result of G. Ofer, if X is excellent, regular, and of dimension 2.

Here are cases where X is strongly desingularizable:

a) X is excellent of characteristic zero;

b) X is locally noetherian, regular, and of dimension ≤ 1;

c) X is of finite type over $\mathbb{Z}$ or over a perfect field, and of dimension ≤ 2.[8]

3.1.6. Cohomological finiteness. Let $f : X \to Y$ be a morphism of preschemes, and let $F \in \operatorname{ob} \mathrm{D}_c^+(X)$. One has $\mathrm{R}f_*(F) \in \operatorname{ob} \mathrm{D}_c^+(Y)$ in the following cases:

a) f is proper and of finite presentation (SGA A, Exposé XIV, 1.1);

b) "when resolution of singularities and the purity theorem are available", in particular:

(i) if X and Y are locally of finite type over a field k of characteristic zero and f is a k-morphism of finite type (SGA A, Exposé XVI, 5.1);

(ii) if Y is excellent of characteristic zero and f is of finite type (SGA A, Exposé XIX, 5.1);

(iii) if X is locally of finite type over a field and $\dim(X) \leq 2$ (SGA A, Exposé XIX, 5.1).

3.2. The quasi-injective dimension of A_X

Proposition 3.2.1. Let X be a regular prescheme whose residual characteristics are prime to n. Suppose that X satisfies (reg) (3.1.1) and $(\mathrm{cdloc})_n$ (3.1.3), and that absolute purity is true on X (3.1.4). Then, for every constructible A_X-module F and every $x \in X$, one has

$$\underline{\mathrm{Ext}}^i(F, A_X)_x = 0 \qquad \text{for } i > 2 \dim \mathcal{O}_{X,x}. \tag{*}$$

Proof. The question being local, we may suppose X affine. By dévissage (3.1.2), it is enough to verify $(*)$ for $F = i_!(G)$, where $i : Y \to X$ is the immersion of a regular integral sub-prescheme, closed in an open subset $D(f)$, $f \in A(X)$, and G is a locally constant constructible sheaf on Y. We must compute

$$\underline{\mathrm{Ext}}^q(F, A_X) = \mathrm{H}^q(\mathrm{R}\,\underline{\mathrm{Hom}}(F, A_X)).$$

The projection formula for i (SGA A, Exposé XVIII) gives

$$\mathrm{R}\,\underline{\mathrm{Hom}}(i_!G, A_X) \xrightarrow{\sim} \mathrm{R}i_*\mathrm{R}\,\underline{\mathrm{Hom}}(G, \mathrm{R}^!i(A_X)).$$

By purity,

$$\mathrm{R}^!i(A_X) \xrightarrow{\sim} (\mu_n)_Y^{\otimes -d}[-2d],$$

where $d = \operatorname{codim}(Y, X)$. Put $T = (\mu_n)_Y^{\otimes -d}$. Since G is locally constant constructible, for every geometric point $\overline{y}$ of Y and every p one has

$$\underline{\mathrm{Ext}}^p(G, T)_{\overline{y}} \xrightarrow{\sim} \mathrm{Ext}^p(G_{\overline{y}}, T_{\overline{y}}).$$

[8] Added in 1977: more generally, if X is excellent noetherian of dimension ≤ 2, by H. Hironaka, *Desingularization of excellent surfaces*, notes by B. Bennett, Bowdoin College, 1967, to be supplemented if necessary by H. Hironaka, *Certain numerical characters of singularities*, J. Math. Kyoto Univ. 10 (1970), 151–187.

But $T_{\overline{y}}$ is injective, being isomorphic to $A = \mathbb{Z}/n\mathbb{Z}$. Hence $\underline{\mathrm{Ext}}^p(G,T) = 0$ for $p \neq 0$, and

$$\mathrm{R}\,\underline{\mathrm{Hom}}(G,T) \xrightarrow{\sim} \underline{\mathrm{Hom}}(G,T).$$

Thus

$$\mathrm{R}\,\underline{\mathrm{Hom}}(F,A_X) \xrightarrow{\sim} \mathrm{R}i_*(\mathcal{H})[-2d], \qquad \mathcal{H} = \underline{\mathrm{Hom}}(G,T).$$

Let Z be the schematic closure of Y in X (EGA I, 9.5.10). Then $Y = Z \cap D(f)$ (EGA 0_{I}, 2.1.6). Denote by $j : Y \to Z$ and $k : Z \to X$ the canonical immersions. We have $\mathrm{R}i_* = k_*\mathrm{R}j_*$, so we are reduced to computing $\mathrm{R}j_*(\mathcal{H})$. If $\overline{x}$ is a geometric point of Z, let $\widetilde{Z} = \mathrm{Spec}(\mathcal{O}_{Z,\overline{x}})$ be the strict localization, let $\widetilde{f}$ be the image of f in $\mathcal{O}_{Z,\overline{x}}$, let $\widetilde{Y} = \widetilde{Z} \times_X Y = \widetilde{Z} - V(\widetilde{f})$, and let $\widetilde{\mathcal{H}}$ be the inverse image of $\mathcal{H}$ on $\widetilde{Y}$. By SGA A, Exposé VIII, 5.2,

$$\mathrm{R}^q j_*(\mathcal{H})_{\overline{x}} \xrightarrow{\sim} \mathrm{H}^q(\widetilde{Y},\widetilde{\mathcal{H}}),$$

hence

$$\underline{\mathrm{Ext}}^q(F,A_X)_{\overline{x}} \xrightarrow{\sim} \mathrm{H}^{q-2d}(\widetilde{Y},\widetilde{\mathcal{H}}).$$

The condition $(\mathrm{cdloc})_n$ implies that this group is zero for

$$q - 2d > \dim \mathcal{O}_{Z,x}.$$

Using

$$d = \mathrm{codim}_x(Z,X) \leq \dim \mathcal{O}_{X,x}$$

(EGA IV, 5.1.3) and

$$\dim \mathcal{O}_{Z,x} = \dim \mathcal{O}_{X,x} - \mathrm{codim}_x(Z,X)$$

(EGA 0_{IV}, 16.5.12 and EGA IV, 5.1.9), one obtains

$$\underline{\mathrm{Ext}}^q(F,A_X)_x = 0 \qquad (q > 2\dim \mathcal{O}_{X,x}),$$

as required. □

Remark 3.2.2. The bound obtained in 3.2.1 is the best possible. Indeed, let x be a point of X, and let Y be the closed integral sub-prescheme of X whose generic point is x. Since X satisfies (reg), there exists a regular open subset U of Y containing x. By purity,

$$\underline{\mathrm{Ext}}^{2d}(A_U,A_X)|U = (\mu_n)_U^{\otimes d},$$

where $d = \dim \mathcal{O}_{X,x} = \mathrm{codim}(Y,X)$.

Corollary 3.2.3. Let X be a regular prescheme of dimension d. If X is smooth over a field k of characteristic prime to n, or if X is excellent of characteristic zero, then X satisfies the conclusion of 3.2.1; consequently

$$\dim . q. inj(A_X) \leq 2d.$$

Proof. If X is excellent of characteristic zero, or if k is perfect of characteristic prime to n and X is smooth over k, then the hypotheses of 3.2.1 are satisfied by 3.1.1, 3.1.3, and 3.1.4. The conclusion is still valid when X is smooth over an arbitrary field k, as follows immediately after the base change $\mathrm{Spec}(k') \to \mathrm{Spec}(k)$, where k' is a perfect closure of k (SGA A, Exposé VIII, 1.1). □

Lemma 3.2.4. Let X be a prescheme satisfying the conclusion of 3.2.1 and of dimension $\leq d$. If there exists an integer N such that X has cohomological dimension $\leq N$, then

$$\dim . inj(A_X) \leq 2d + N.$$

If, moreover, for every closed subset Y of X, the implication

$$\operatorname{codim}(Y, X) \geq p \quad \Rightarrow \quad \operatorname{cd}_{\mathbf{n}}(Y) \leq N - 2p$$

holds, then

$$\dim . inj(A_X) \leq N.$$

Proof. The first assertion follows immediately from 1.5. For the second, one argues as in 1.5. We are reduced to proving, for F constructible on X, the relation

$$\operatorname{Ext}^i(X; F, A_X) = 0 \qquad (i > N).$$

For this, inspect the spectral sequence

$$E_2^{pq} = \mathrm{H}^p(X; \underline{\operatorname{Ext}}^q(F, A_X)) \Rightarrow \operatorname{Ext}^*(X; F, A_X).$$

By 3.2.1, the sheaves $\underline{\operatorname{Ext}}^{2i}(F, A_X)$ and $\underline{\operatorname{Ext}}^{2i-1}(F, A_X)$ are concentrated in codimension $\geq i$. Therefore $E_2^{p,2i} = E_2^{p,2i-1} = 0$ for $p > N - 2i$, by the hypothesis. Hence $E_2^{pq} = 0$ for $p + q > N$, and the assertion follows. □

Corollary 3.2.5. If X is a smooth prescheme of dimension d over a separably closed field k of characteristic prime to n, then

$$\dim . inj(A_X) = 2d.$$

Proof. By 3.2.3 and SGA A, Exposé X, 4.2, we are in the situation of 3.2.4. The hypotheses of SGA A, Exposé X, 4.2 are satisfied by SGA A, Exposé X, 2.1 and 3.2; hence $\dim . inj(A_X) \leq 2d$. The equality follows from purity: if x is a closed point of codimension d in X, then

$$\operatorname{Ext}^{2d}(X, A_x, A_X) = \mathrm{H}^{2d}_x(A_X) \xrightarrow{\sim} (\mu_n)^{\otimes d}(k) \neq 0.$$

□

3.3. Constructibility of the sheaves $\underline{\operatorname{Ext}}^i(F, A_X)$

Proposition 3.3.1. Let X be a prescheme.

a) The following conditions are equivalent:

(i) for $F \in \operatorname{ob} \mathrm{D}_c^-(X)$ and $G \in \operatorname{ob} \mathrm{D}_c^+(X)$, one has

$$\mathrm{R}\,\underline{\operatorname{Hom}}(F, G) \in \operatorname{ob} \mathrm{D}_c^+(X);$$

(i bis) for every pair (F, G) of constructible A_X-modules, one has $\mathrm{R}\,\underline{\operatorname{Hom}}(F, G) \in \operatorname{ob} \mathrm{D}_c^+(X)$, i.e. the sheaves $\underline{\operatorname{Ext}}^i(F, G)$ are constructible for all i;

(ii) for every open immersion $i : U \to X$ and every constructible A_U-module F, the sheaves $\mathrm{R}^p i_*(F)$ are constructible for all p;

(ii bis) for every immersion $i : Y \to X$ and every constructible A_Y-module F, the sheaves $\mathrm{R}^p i_*(F)$ are constructible for all p;

(ii ter) for every immersion $i : Y \to X$ and every locally constant constructible A_Y-module F, the sheaves $\mathrm{R}^p i_*(F)$ are constructible for all p;

(iii) for every finite morphism, respectively every closed immersion, $f : Y \to X$, and every $F \in \mathrm{ob}\, \mathrm{D}_c^+(X)$, one has $\mathrm{R}^! f(F) \in \mathrm{ob}\, \mathrm{D}_c^+(Y)$.

b) These conditions are satisfied in each of the following two cases:

(i) $\dim(X) \leq 1$;

(ii) resolution of singularities and purity are available on X in the sense of 3.1.6(b).

Proof. The equivalence of (i) and (i bis) follows from the standard spectral sequence passing from sheaf-Ext to hyper-Ext.

(i bis) $\Rightarrow$ (ii). Let $\overline{F}$ be a constructible A_X-module extending F, for example $\overline{F} = i_! F$. By duality (SGA A, Exposé XVIII, 3.1.10),

$$\mathrm{R}i_* F = \mathrm{R}i_* \mathrm{R}\,\underline{\mathrm{Hom}}(A_U, i^! \overline{F}) \xrightarrow{\sim} \mathrm{R}\,\underline{\mathrm{Hom}}(i_! A_U, \overline{F}),$$

and this proves the claim.

(ii) $\Rightarrow$ (ii bis). Factor i as a closed immersion followed by an open immersion.

(ii bis) $\Rightarrow$ (i bis). The question is local, so we may suppose X affine. By the usual dévissage (SGA A, Exposé IX, 2.5), it is enough to verify (ii) for $F = i_! M$, where $i : Y \to X$ is the immersion of a sub-prescheme and M is a locally constant constructible A_Y-module. By the projection formula (SGA A, Exposé XVIII),

$$\mathrm{R}\,\underline{\mathrm{Hom}}(i_! M, G) \xrightarrow{\sim} \mathrm{R}i_* \mathrm{R}\,\underline{\mathrm{Hom}}(M, \mathrm{R}i^! G),$$

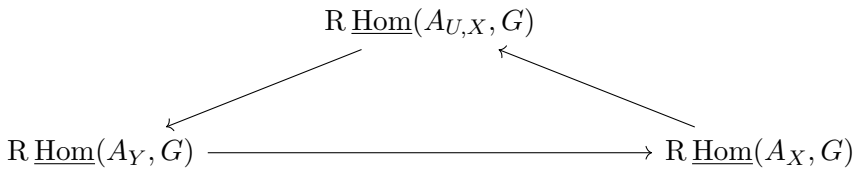
and by a spectral sequence we are reduced to proving that

$$\mathrm{R}\,\underline{\mathrm{Hom}}(M, \mathrm{R}i^! G) \in \mathrm{ob}\, \mathrm{D}_c^+(Y).$$

First prove $\mathrm{R}i^! G \in \mathrm{ob}\, \mathrm{D}_c^+(Y)$. After factoring i, we may suppose that Y is closed. Let $j : U = X - Y$ be the complementary open immersion. Applying $\mathrm{R}\,\underline{\mathrm{Hom}}(\ , G)$ to

$$0 \longrightarrow A_{U,X} \longrightarrow A_X \longrightarrow A_Y \longrightarrow 0$$

gives a distinguished triangle.



Since $\mathrm{R}\,\underline{\mathrm{Hom}}(A_X, G) = G$, and

$$\mathrm{R}\,\underline{\mathrm{Hom}}(A_{U,X}, G) \xrightarrow{\sim} \mathrm{R}j_* j^! G$$

belongs to $\mathrm{D}_c^+(X)$ by hypothesis, it follows that

$$\mathrm{R}\,\underline{\mathrm{Hom}}(A_Y, G) \xrightarrow{\sim} i_*\mathrm{R}i^!G$$

belongs to $\mathrm{D}_c^+(X)$. Resolving M locally on Y, for the étale topology, by free A_Y-modules, another dévissage gives

$$\mathrm{R}\,\underline{\mathrm{Hom}}(M, \mathrm{R}i^!G) \in \mathrm{ob}\,\mathrm{D}_c^+(Y).$$

This proves the implication.

(ii bis) $\Rightarrow$ (ii ter) is trivial.

(ii ter) $\Rightarrow$ (ii). Let $i : U \to X$ be an open immersion and let F be a constructible A_U-module. We must prove $\mathrm{R}i_*F \in \mathrm{ob}\,\mathrm{D}_c^+(X)$. The question being local, suppose X noetherian and argue by noetherian induction on X. We may suppose $U \neq \varnothing$. Then there exists a non-empty open subset $j : V \to U$ such that j^*F is locally constant (SGA A, Exposé IX, 2.4). Let M be the mapping cylinder of

$$F \longrightarrow \mathrm{R}j_*j^*F.$$

Applying $\mathrm{R}i_*$ gives a distinguished triangle

$$\begin{array}{ccc} & \mathrm{R}i_*(M) & \\ {\scriptstyle (+1)}\swarrow & & \nwarrow \\ \mathrm{R}i_*(F) & \longrightarrow & \mathrm{R}i_*\mathrm{R}j_*j^*(F) \end{array}$$

Condition (ii ter) implies

$$\mathrm{R}i_*\mathrm{R}j_*j^*F \xrightarrow{\sim} \mathrm{R}(ij)_*j^*F \in \mathrm{ob}\,\mathrm{D}_c^+(X).$$

Consequently,

$$\mathrm{R}j_*j^*F \xrightarrow{\sim} i^*\mathrm{R}(ij)_*j^*F \in \mathrm{ob}\,\mathrm{D}_c^+(U).$$

Thus $M \in \mathrm{ob}\,\mathrm{D}_c^+(U)$, since $F \in \mathrm{ob}\,\mathrm{D}_c^+(U)$. Moreover, the cohomology of M is supported on a closed subset Z of U distinct from U. Applying the induction hypothesis to $U \cap \overline{Z} \to \overline{Z}$, we deduce $\mathrm{R}i_*M \in \mathrm{ob}\,\mathrm{D}_c^+(X)$, and hence $\mathrm{R}i_*F \in \mathrm{ob}\,\mathrm{D}_c^+(X)$.

The equivalence of (i)–(ii ter) with condition (iii) is left to the reader; use 1.14.

For b)(i), normalization reduces one to the case where X is regular, and one uses purity, which will be proved in 5.1. For b)(ii), see 3.1.6(b). □

3.4. The biduality theorem on regular preschemes

Theorem 3.4.1, cf. [H], V, 2.2. Let X be a regular locally noetherian prescheme of finite dimension. Suppose that X is strongly desingularizable (3.1.5), satisfies (reg) (3.1.1) and $(\mathrm{cdloc})_n$ (3.1.3), and that absolute purity (3.1.4) is true on every prescheme smooth over X. Then A_X is dualizing.

Proof. We must prove that A_X satisfies conditions (i)–(iii) of 1.6. Condition (i) follows from 3.2.1. Condition (ii) follows from 3.3.1(b). It remains to prove condition (iii). Thus, by 1.7, for every constructible A_X-module F we must prove that the canonical homomorphism

$$F \longrightarrow \underline{D}_X\underline{D}_X F, \qquad \underline{D}_X = \mathrm{R}\,\underline{\mathrm{Hom}}(\ , A_X),$$

is an isomorphism. The question being local, suppose X noetherian. By dévissage (3.1.2, iii bis), it is enough to treat sheaves

$$F = f_* i_!(A'_U),$$

where $i : U \to Y$ is the inclusion of a regular open subset of an integral prescheme, $f : Y \to X$ is finite and the generic point of Y is separable over its image, and $A' = \mathbb{Z}/\ell\mathbb{Z}$ for a prime divisor ℓ of n.

Because X is strongly desingularizable, there is a proper birational morphism $h : Y' \to Y$, with Y' regular, inducing an isomorphism from $U' = h^{-1}U$ to U, and such that $Y' - U'$ is a normal crossings divisor. By base change (SGA A, Exposé XVII),

$$i_!(A'_U) \xrightarrow{\sim} \mathrm{R}h_* i'_!(A'_{U'}),$$

where $i' : U' \to Y'$ is the inclusion. Hence, with $g = fh$,

$$f_* i_!(A'_U) \xrightarrow{\sim} f_* \mathrm{R}h_* i'_!(A'_{U'}) \xrightarrow{\sim} \mathrm{R}g_* i'_!(A'_{U'}).$$

By 1.11, it suffices to prove that the pair

$$(i'_!(A'_{U'}), \mathrm{R}^! g(A_X))$$

is bidualizing. Locally immersing Y' in a prescheme X' smooth over X, and applying purity on X', one sees that $\mathrm{R}^! g(A_X)$ is locally isomorphic to $A_{Y'}$, up to a translation of degrees. We are therefore reduced to the following special case.

Lemma 3.4.2. Let X be a locally noetherian regular prescheme on which absolute purity is true. Let $Y = Y_1 \cup \cdots \cup Y_p$ be a strict normal crossings divisor on X, and put $U = X - Y$. Then the pair $(A'_{U,X}, A_X)$ is bidualizing.

Proof. By the exact sequence

$$0 \longrightarrow A'_{U,X} \longrightarrow A'_X \longrightarrow A'_Y \longrightarrow 0,$$

it is equivalent to verify that (A'_Y, A_X) is bidualizing. We argue by induction on p.

If $p = 1$, let $i : Y \to X$ be the immersion. By 1.11, it is enough to verify that

$$(A'_Y, \mathrm{R}^! i(A_X))$$

is bidualizing. By purity,

$$\mathrm{R}^! i(A_X) \xrightarrow{\sim} (\mu_n)_Y^{\otimes -1}[-2].$$

Thus the canonical homomorphism $A'_Y \to \underline{D}_Y \underline{D}_Y(A'_Y)$ is an isomorphism, as is checked trivially fibre by fibre, using Pontryagin duality for A-modules.

Suppose $p \geq 2$, and put $Y' = Y_1 \cup \cdots \cup Y_{p-1}$. We have an exact sequence

$$0 \longrightarrow A'_{(Y-Y'),X} \longrightarrow A'_Y \longrightarrow A'_{Y'} \longrightarrow 0.$$

By the induction hypothesis, $(A'_{Y'}, A_X)$ is bidualizing. By the five lemma, we are reduced to biduality for $(A'_{(Y-Y'),X}, A_X)$. But again there is an exact sequence

$$0 \longrightarrow A'_{(Y-Y'),X} \longrightarrow A'_{Y_p} \longrightarrow A'_{Y_p \cap Y'} \longrightarrow 0.$$

Since (A'_{Y_p}, A_X) is bidualizing, it remains to prove the same for $(A'_{Y_p\cap Y'}, A_X)$. Applying 1.11 again and using purity, we are finally reduced to biduality for $(A'_{Y_p\cap Y'}, A_{Y_p})$ on Y_p, where the induction hypothesis applies. □

This completes the proof of Theorem 3.4.1.

Corollary 3.4.3. Let S be an excellent noetherian regular prescheme of characteristic zero. Then A_S is dualizing. Moreover, if $f : X \to S$ is a morphism of finite type, then $\mathrm{R}^!f(A_S)$ is dualizing.

Proof. The first assertion follows because S satisfies the hypotheses of 3.4.1, as recalled in 3.1. For the second, one must first verify that $\mathrm{R}^!f(A_S)$ has finite quasi-injective dimension. Cover S by finitely many affine open subsets S_i such that $X_i = f^{-1}(S_i)$ is a finite union of affine open subsets X_{ij} immersed as closed subschemes in preschemes X'_{ij} smooth of finite dimension over S_i. From 3.2.3 and 1.6 it follows that

$$\dim . q. inj(\mathrm{R}^!f(A_S)) \leq 2 \sup \dim X'_{ij}.$$

It remains to verify conditions (ii) and (iii) of 1.7. Since these are local on X for the étale topology, we may suppose that f factors as $f = f'i$, where $f' : X' \to S$ is smooth of relative dimension d, and $i : X \to X'$ is a closed immersion. Then

$$\mathrm{R}^!f(A_S) \simeq \mathrm{R}^!i\,\mathrm{R}^!f'(A_S).$$

But $\mathrm{R}^!f'(A_S)$ is locally isomorphic to $A_{X'}$, up to the translation by $2d$, hence is dualizing by the first assertion. By 1.15, $\mathrm{R}^!f(A_S)$ is dualizing, and in particular satisfies conditions (ii) and (iii) of 1.7. □

Corollary 3.4.4. Let k be a field, and let $f : X \to S = \mathrm{Spec}(k)$ be a morphism locally of finite type, with $\dim(X) \leq 2$. Then $\mathrm{R}^!f(A_S)$ is dualizing.

Proof. Replacing k by its perfect closure, which is harmless for the étale topology (SGA A, Exposé VIII, 1.1), we may suppose k perfect. Cover X by affine open subsets X_i of finite type over k. Since $\dim(X_i) \leq 2$, the normalization lemma makes X_i finite over a scheme X'_i smooth over S and of dimension ≤ 2. By 1.15 this reduces us to the case where f is smooth, hence locally

$$f^!(A_S) \simeq A_X[2d].$$

Thus it remains to show that A_X is dualizing in this case; this is exactly 3.4.1, since the hypotheses are satisfied (see 3.1). □

Remark 3.4.5. We shall see below that if X is regular of dimension ≤ 1, then A_X is dualizing.

4. Local duality

The object of this section is to present the notion of "biduality" developed in the preceding sections in a form closer to geometric intuition.

4.1

Let X be a prescheme, let $i : x \to X$ be a closed point whose residue field is separably closed, and let K_X be a dualizing complex on X (1.7). We know (1.15) that $K_{\{x\}} = \mathrm{R}^! i(K_X)$ is a dualizing complex on x, hence, by (2.1) and (3.4.4), isomorphic to $A[r]$ for some $r \in \mathbb{Z}$ (if A is local). We shall say that K_X is *normalized at* x if $r = 0$ and if an isomorphism $K_{\{x\}} \xrightarrow{\sim} A$ has been given.

For example, if X is smooth of relative dimension d over the spectrum of a separably closed field, the complex $(\mu_n)_X^{\otimes d}[2d]$ is, by the purity theorem (SGA XVI 3, SGA $4^{1/2}$ Cycle 2.3), canonically normalized at every closed point of X.

4.2

Let X be a prescheme, $i : Y \to X$ a closed sub-prescheme, and K_X a dualizing complex on X. Then (1.15) $K_Y = \mathrm{R}^! i(K_X)$ is a dualizing complex on Y, and one has the *complementary induction formula* (1.12 b) (ii)), for $F \in \mathrm{ob}\, \mathrm{D}_c^b(X)$,

$$(4.2.1) \qquad i^* \underline{D}_X(F) \xrightarrow{\sim} \underline{D}_Y \mathrm{R}^! i(F),$$

where $\underline{D}_X = \mathrm{R}\,\underline{\mathrm{Hom}}(\ , K_X)$ and $\underline{D}_Y = \mathrm{R}\,\underline{\mathrm{Hom}}(\ , K_Y)$.

Apply (4.2.1) in particular in the case where $Y = \{x\}$ is a closed point of X with separably closed residue field, K_X being normalized at x (4.1). Taking into account that A_x is injective, (4.2.1) is then written

$$(4.2.2) \qquad \underline{D}_X(F)_x \xrightarrow{\sim} \mathrm{Hom}^*(\mathrm{R}^! i(F), A).$$

Noting that $\mathrm{R}^! i(F)$ is also written, by definition, $\mathrm{R}\Gamma_x(F)$, one therefore has a perfect pairing in $\mathrm{D}(A)$:

$$(4.2.2)' \qquad \underline{D}_X(F)_x \times \mathrm{R}\Gamma_x(F) \longrightarrow A,$$

giving rise to perfect pairings between finite groups:

$$(4.2.2)'' \qquad \underline{\mathrm{H}}^i(\underline{D}_X(F))_x \times \underline{\mathrm{H}}_x^{-i}(F) \longrightarrow A.$$

For example, let X be a prescheme smooth of dimension d over a separably closed field, and let $x \in X$ be a closed point. Then, for $F \in \mathrm{ob}\, \mathrm{D}_c^b(X)$, one has a canonical perfect duality between finite groups:

$$(4.2.2)''' \qquad \mathrm{Ext}^{2d-i}(F, (\mu_n)_X^{\otimes d})_x \times \underline{\mathrm{H}}_x^i(F) \longrightarrow A.$$

Exercise 4.2.3

Let X be a strictly local scheme (SGAA VIII 4.2), with closed point x, and let $i : x \to X$ be the canonical morphism. Let K be a dualizing complex on X, normalized at x. Denote by

$$\mathbf{L}\, i_? : \mathrm{D}^b(A) \longrightarrow \mathrm{D}^-(X)$$

the functor defined by

$$\mathbf{L}\, i_?(M) = M \overset{\mathbf{L}}{\otimes}_A K.$$

(If K has finite tor-dimension over A, $\mathbf{L}\, i_?$ extends to a functor from $\mathrm{D}^+(A)$ to $\mathrm{D}(X)$.)

Show that there exists, for $L \in \mathrm{D}^-(X)$ and $M \in \mathrm{D}^b(A)$, a canonical functorial isomorphism

$$(*) \qquad \mathrm{R}\,\mathrm{Hom}(L, \mathbf{L}\, i_?(M)) \xrightarrow{\sim} \mathrm{R}\,\mathrm{Hom}(\mathrm{R}^!i(L), M),$$

(assuming of course that $\mathrm{R}^!i : \mathrm{D}^-(X) \to \mathrm{D}^-(A)$ is defined ...).

Hint: First define a "trace" morphism $\mathrm{R}^!i\,\mathbf{L}\,i_?(M) \to M$; then, to check that $(*)$ is an isomorphism, reduce by dévissage to the case where $L \in \mathrm{ob}\,\mathrm{D}^b_c(X)$ and $M = A$, and apply (4.2.2). Note that, for $M = A$, $(*)$ reduces to the perfect pairing ("local duality", cf. [H] V 6.2)

$$\mathrm{R}\Gamma_x(L) \times \mathrm{R}\,\mathrm{Hom}(L, K) \longrightarrow A,$$

or

$$\mathrm{H}^i_x(L) \times \mathrm{Ext}^{-i}(L, K) \longrightarrow A.$$

4.3

We shall now generalize (4.2.2) to the case of a geometric point $\overline{x}$ of X localized at a point x which is not necessarily closed. For this we need a few preliminaries.

Lemma 4.3. Let X be a prescheme, X' the strict localization of X at a geometric point $\overline{x}$, and $f : X' \to X$ the canonical map. Then, for $F \in \mathrm{ob}\,\mathrm{D}^-_c(X)$ and $G \in \mathrm{ob}\,\mathrm{D}^+(X)$, the canonical functorial homomorphism (SGAA VI I 3.7)

$$f^*\mathrm{R}\,\underline{\mathrm{Hom}}(F, G) \longrightarrow \mathrm{R}\,\underline{\mathrm{Hom}}(f^*F, f^*G)$$

is an isomorphism.

Proof. As usual, one reduces to F and G concentrated in degree 0. Since the question is local in a neighborhood of x, one may suppose X affine. Then F admits (SGAA IX 2.7) a left resolution by sheaves of the form $i_!(A_U)$, where $i : U \to X$ is étale of finite presentation; hence, by dévissage, one is reduced to $F = i_!(A_U)$. Form the cartesian square

$$\begin{array}{ccc} U & \xleftarrow{g} & U' \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle i'} \\ X & \xleftarrow[f]{} & X' \end{array}$$

One has canonical isomorphisms, trivial special cases of duality (SGAA XVIII 3.1.10):

$$\mathrm{R}\,\underline{\mathrm{Hom}}(F, G) \xleftarrow{\sim} \mathrm{R}i_*i^*G, \qquad \mathrm{R}\,\underline{\mathrm{Hom}}(f^*F, f^*G) \xleftarrow{\sim} \mathrm{R}i'_*g^*i^*G.$$

Under these isomorphisms, the canonical arrow

$$f^*\mathrm{R}\,\underline{\mathrm{Hom}}(F, G) \longrightarrow \mathrm{R}\,\underline{\mathrm{Hom}}(f^*F, f^*G)$$

is identified with the base-change arrow (SGAA XVII)

$$f^*\mathrm{R}i_*i^*(G) \longrightarrow \mathrm{R}i'_*g^*i^*(G).$$

But this is an isomorphism, as one sees at once by passing to the limit (SGAA VII 5.11).

Lemma 4.4. Let X be a prescheme, and let $K \in \mathrm{ob}\,\mathrm{D}_c^+(X)$ be a complex satisfying conditions (i) and (ii) of (1.7). In order that K be dualizing, it is necessary and sufficient that, for every strict localization $f : \overline{X}(\overline{x}) \to X$, f^*K be dualizing.

Proof. Use the fact that every constructible sheaf on a strict localization $\overline{X}(\overline{x})$ is induced by a constructible sheaf on an étale $\overline{x}$-pointed scheme over X (SGAA IX 2.7.4), and apply (4.3).

4.5

Let X be a prescheme, $\overline{x}$ a geometric point of X, and $f : X' = \overline{X}(\overline{x}) \to X$ the corresponding strict localization.

Let Y be the integral closed sub-prescheme which is the closure of x in X; denote by $g : \overline{x} \to Y$ and $i : Y \to X$ the canonical maps, and form the cartesian square

$$\begin{array}{ccc} Y & \xrightarrow{i} & X \\ {\scriptstyle g}\uparrow & & \uparrow{\scriptstyle f} \\ \overline{x} & \xrightarrow[i']{} & X' \end{array}$$

($\overline{x}$ is both the closed point of X' and the strict localization of Y at $\overline{x}$).

We shall denote by

$$\mathrm{R}\Gamma_{\overline{x}} : \mathrm{D}^+(X) \longrightarrow \mathrm{D}^+(\overline{x})$$

the functor defined by

$$\mathrm{R}\Gamma_{\overline{x}} = g^*\mathrm{R}^!i. \tag{4.5.1}$$

Using the well-known relation between the functors $\mathrm{R}^!i$ and $\mathrm{R}j_*j^*$, where $j : U \to X$ is the open complement of Y, and applying passage to the limit (SGAA VII 5.11), one obtains a canonical isomorphism

$$\mathrm{R}\Gamma_{\overline{x}} \xrightarrow{\sim} \mathrm{R}^!i'f^*. \tag{4.5.2}$$

When x is a closed point with separably closed residue field, the functor $\mathrm{R}\Gamma_{\overline{x}}$ coincides with the usual functor $\mathrm{R}\Gamma_x$ (SGAA V 4.3), which justifies the notation.

Let $K_X \in \mathrm{ob}\,\mathrm{D}^+(X)$, and put $K_Y = \mathrm{R}^!i(K_X)$, $K_{X'} = f^*K_X$, and $K_{\overline{x}} = \mathrm{R}\Gamma_{\overline{x}}(K_X)$ (warning: $K_{\overline{x}}$ is not the fiber of K_X at $\overline{x}$!). Suppose that K_X is dualizing. Then, by (1.15) and (4.4), the same is true of $K_{X'}$, K_Y, and $K_{\overline{x}}$. Hence (2.1) one has $K_{\overline{x}} \simeq A[d]$ for some $d \in \mathbb{Z}$.

We shall say that K_X is *normalized at* $\overline{x}$ if $d = 0$ and if an isomorphism $K_{\overline{x}} \simeq A$ has been chosen. In the case where x is closed with separably closed residue field, this recovers the notion introduced in (4.1).

Let K_X be a dualizing complex, and put $\underline{D}_X = \mathrm{R}\underline{\mathrm{Hom}}(\ , K_X)$, $\underline{D}_Y = \mathrm{R}\underline{\mathrm{Hom}}(\ , K_Y)$, etc. Let $F \in \mathrm{ob}\,\mathrm{D}_c^b(X)$; let us compute $(\underline{D}_X F)_{\overline{x}}$. One has:

$$\begin{aligned} (\underline{D}_X F)_{\overline{x}} &\xrightarrow{\sim} g^*i^*\underline{D}_X F \\ &\xrightarrow{\sim} g^*\underline{D}_Y \mathrm{R}^!i F \qquad \text{(by the complementary induction formula (4.2.1))} \\ &\xrightarrow{\sim} \underline{D}_{\overline{x}} g^*\mathrm{R}^!i(F) \qquad \text{(by (4.3)), that is,} \end{aligned}$$

$$(\underline{D}_X F)_{\overline{x}} \xrightarrow{\sim} \underline{D}_{\overline{x}}\mathrm{R}\Gamma_{\overline{x}}(F). \tag{4.5.3}$$

Of course, one could have made an analogous computation by passing through X' instead of Y; one would then have obtained a canonical isomorphism

$$(\underline{D}_X F)_{\overline{x}} \xrightarrow{\sim} \underline{D}_{\overline{x}} \mathrm{R}^! i'^* f^*(F),$$

compatible with (4.5.3) by means of the identification (4.5.2).

If moreover K_X is normalized at $\overline{x}$, one obtains perfect pairings generalizing (4.2.2)' and (4.2.2)":

$$(4.5.3)' \qquad \underline{D}_X(F)_{\overline{x}} \times \mathrm{R}\Gamma_{\overline{x}}(F) \longrightarrow A,$$

$$(4.5.3)'' \qquad \underline{\mathrm{H}}^i(\underline{D}_X(F)_{\overline{x}}) \times \underline{\mathrm{H}}_{\overline{x}}^{-i}(F) \longrightarrow A,$$

where $\underline{\mathrm{H}}_{\overline{x}}^i = \underline{\mathrm{H}}^i \mathrm{R}\Gamma_{\overline{x}}$.

Conversely, let $K_X \in \mathrm{ob}\,\mathrm{D}^+(X)$ satisfy conditions (i) and (ii) of (1.7), and suppose that $K_{\overline{x}} = \mathrm{R}\Gamma_{\overline{x}}(K_X)$ is dualizing for every geometric point $\overline{x}$ of X. Then, for every $\overline{x}$, one can define (cf. 1.12 b) (ii)) a canonical arrow

$$(4.5.3)^{\mathrm{bis}} \qquad \underline{D}_X(F)_{\overline{x}} \longrightarrow \underline{D}_{\overline{x}} \mathrm{R}\Gamma_{\overline{x}}(F) \qquad (F \in \mathrm{ob}\,\mathrm{D}_c^b(X)).$$

If this is an isomorphism for every $\overline{x}$ and every F, then K_X is dualizing. Indeed, it remains to verify that the canonical arrow

$$F \longrightarrow \underline{D}_X \underline{D}_X(F)$$

is an isomorphism for every $F \in \mathrm{ob}\,\mathrm{D}_c^b(X)$. At an arbitrary geometric point $\overline{x}$, one has

$$\begin{aligned} F_{\overline{x}} &\xrightarrow{\sim} \underline{D}_{\overline{x}} \underline{D}_{\overline{x}}(F_{\overline{x}}) \qquad \text{(since } K_{\overline{x}} \text{ is dualizing)} \\ &\xrightarrow{\sim} \underline{D}_{\overline{x}} \mathrm{R}\Gamma_{\overline{x}} \underline{D}_X(F) \qquad \text{(by (4.3) and the induction formula 1.12 b) (i))} \\ &\xrightarrow{\sim} \underline{D}_X \underline{D}_X(F)_{\overline{x}} \qquad \text{(by hypothesis),} \end{aligned}$$

and therefore, modulo a compatibility check, (F, K_X) is bidualizing, which proves the assertion. In summary:

Proposition 4.5.4. Let X be a prescheme, and let $K_X \in \mathrm{ob}\,\mathrm{D}^+(X)$ be a complex satisfying conditions (i) and (ii) of (1.7). In order that K_X be dualizing, it is necessary and sufficient that, for every geometric point $\overline{x}$ of X, the complex $K_{\overline{x}}$ be dualizing and the canonical arrow $(4.5.3)^{\mathrm{bis}}$ be an isomorphism for every $F \in \mathrm{ob}\,\mathrm{D}_c^b(X)$.

Remark 4.5.5. The existence of dualizing complexes should be regarded, in a sense, as an important complement to the global duality theorem. Indeed, the latter expresses that, for a separated morphism of finite type $f : X \to Y$ (Y quasi-compact), one has a canonical isomorphism

$$\underline{D}_Y \mathrm{R}_! f(F) \xrightarrow{\sim} \mathrm{R}f_* \underline{D}_X(F)$$

(with the notation of 1.12). Its use for computing $\mathrm{R}_! f(F)$ (when $F \in \mathrm{ob}\,\mathrm{D}_c^b(X)$) requires information about $\underline{D}_X(F)$. When K_X is dualizing, this information is supplied by the isomorphism (4.5.3), which makes possible, at least in theory, a computation of the fibers of $\underline{D}_X(F)$ as invariants of "purely spatial" cohomology.

Exercise 4.5.6. Let X be a prescheme endowed with a dualizing complex (1.7). The family of functors (cf. (4.5.3)")

$$\underline{\mathrm{H}}^i_{\overline{x}} : \mathrm{D}^b_c(X) \longrightarrow (A\text{-modules})$$

(i running through $\mathbb{Z}$ and $\overline{x}$ through the set of geometric points of X) is "conservative", i.e. a morphism $F \to G$ in $\mathrm{D}^b_c(X)$ such that the maps $\mathrm{H}^i_{\overline{x}}(F) \to \mathrm{H}^i_{\overline{x}}(G)$ are isomorphisms, is an isomorphism.

4.6

Let X be a prescheme, $j : Y \to X$ a closed sub-prescheme, and $i : \overline{x} \to Y$ a geometric point of Y. Let, on the other hand, K_X be a dualizing complex on X, normalized at $\overline{x}$ (cf. (4.5)). We saw in (4.5) that, if Y is the closure of x, one has, for $F \in \mathrm{ob}\,\mathrm{D}^b_c(X)$, a perfect pairing

$$\mathrm{R}^!j(F)_{\overline{x}} \times \underline{D}_X(F)_{\overline{x}} \longrightarrow A.$$

It is not difficult to define an analogous pairing in the general case. Introduce the factorization of i as

$$\overline{x} \xrightarrow{i'} \overline{\{x\}} \xrightarrow{i''} Y.$$

For $F \in \mathrm{ob}\,\mathrm{D}^b_c(X)$, one has canonical isomorphisms:[9]

$$\begin{aligned}
\mathrm{R}\Gamma_{\overline{x}} j^* \underline{D}_X(F) &\xrightarrow{\sim} \mathrm{R}\Gamma_{\overline{x}} \underline{D}_Y \mathrm{R}^! j(F) \qquad \text{(complementary induction formula (4.2.1))} \\
&\xrightarrow{\sim} i'^* \mathrm{R}^! i'' \underline{D}_Y \mathrm{R}^! j(F) \qquad \text{(definition of } \mathrm{R}\Gamma_{\overline{x}} \text{ (4.5.1))} \\
&\xrightarrow{\sim} i'^* \underline{D}_{\overline{x}} i''^* \mathrm{R}^! j(F) \qquad \text{(ordinary induction (1.12 b) (i))} \\
&\xrightarrow{\sim} \underline{D}_{\overline{x}} i^* \mathrm{R}^! j(F) \qquad \text{(by 4.3)), i.e. finally a}
\end{aligned}$$

canonical isomorphism

$$\text{(4.6.1)} \qquad \mathrm{R}^!j(F)_{\overline{x}} \xrightarrow{\sim} \underline{D}_{\overline{x}} \mathrm{R}\Gamma_{\overline{x}} j^* \underline{D}_X(F),$$

and hence perfect pairings

$$\text{(4.6.1)}' \qquad \mathrm{R}^!j(F)_{\overline{x}} \times \mathrm{R}\Gamma_{\overline{x}} j^* \underline{D}_X(F) \longrightarrow A,$$

$$\text{(4.6.1)}'' \qquad \underline{\mathrm{H}}^i_Y(F)_{\overline{x}} \times \underline{\mathrm{H}}^{-i}_{\overline{x}}(\underline{D}_X(F)|Y) \longrightarrow A.$$

Example 4.6.2. Let X be a regular prescheme, let $\overline{x}$ be a geometric point of X, and put $d = \dim(\mathcal{O}_{X,\overline{x}})$. Set $K_X = (\mu_n)^{\otimes d}_X[2d]$. If X satisfies condition (reg) (3.1.1) and the purity theorem (3.1.4), then K_X is canonically normalized at $\overline{x}$. Thus, if K_X is dualizing, one has perfect pairings

$$\underline{\mathrm{H}}^i_Y(F)_{\overline{x}} \times \underline{\mathrm{H}}^{2d-i}_{\overline{x}}(F'|Y) \longrightarrow A,$$

for every closed subset Y containing x and every $F \in \mathrm{ob}\,\mathrm{D}^b_c(X)$, with $F' = \mathrm{R}\,\mathrm{Hom}(F, (\mu_n)^{\otimes d}_X)$.

To finish, let us give a strictly local variant of (4.6.1).

[9] *Editorial note.* The ordinary-induction line is not unambiguously legible in the printed source. The current source-checked French TeX reads $i'^* \underline{D}_{\overline{x}} i'''^* \mathrm{R}^! j(F)$; type checking through $i'' : \overline{\{x\}} \to Y$ instead suggests the subscript $\overline{\{x\}}$, while the source glyph can resemble X and its first pullback mark is also unclear. This edition retains the French-control reading without claiming that the scan adjudicates it.

4.7

Let X be a noetherian strictly local scheme (SGAA VIII 4.2), with closed point x. Let Y be a non-empty closed subset of X, and consider the canonical immersions

$$U = X - Y \xrightarrow{i} V = X - \{x\} \xrightarrow{j} X.$$

Finally, let K_X be a dualizing complex normalized at x (4.1), giving dualizing complexes "corresponding" on U, V, Y, x (and by hypothesis $\underline{D}_x = \mathrm{R}\,\mathrm{Hom}(\ , A)$):

$$K_V = j^* K_X, \qquad K_U = i^* K_V, \qquad K_Y = \mathrm{R}\Gamma_Y(K_X).$$

Let $G \in \mathrm{ob}\,\mathrm{D}^b_c(U)$, and put $G' = \underline{D}_U(G)$. We propose to define a natural pairing

$$(4.7.1) \qquad \mathrm{R}\Gamma(U, G) \times \mathrm{R}\Gamma(V, i_! G')[-1] \longrightarrow A,$$

i.e. a functorial homomorphism

$$(4.7.1)' \qquad \mathrm{R}\Gamma(U, G) \overset{\mathbf{L}}{\otimes}_A \mathrm{R}\Gamma(V, i_! G')[-1] \longrightarrow A.$$

(Since the ring $A = \mathbb{Z}/\ell\mathbb{Z}$ has infinite cohomological dimension for $\ell \geqslant 2$, one knows how to define only the tensor products

$$\overset{\mathbf{L}}{\otimes} : \mathrm{D}^-(A) \times \mathrm{D}^-(A) \longrightarrow \mathrm{D}^-(A)$$

and

$$\overset{\mathbf{L}}{\otimes} : \mathrm{D}(A) \times \mathrm{D}^b(A)_{\mathrm{torf}} \longrightarrow \mathrm{D}(A) \quad (*).$$

We therefore leave it to the reader to make suitable hypotheses ensuring that the two factors of $\overset{\mathbf{L}}{\otimes}$ appearing in (4.7.1)' are in $\mathrm{D}^b(A)$, or that one of them has finite tor-dimension.)

First note that, by the complementary duality formula (1.12 a) (ii), one has a canonical isomorphism

$$(4.7.2) \qquad i_!(G') \xrightarrow{\sim} \underline{D}_V(\mathrm{R}i_* G).$$

On the other hand, one has the ordinary duality isomorphism

$$(4.7.3) \qquad \mathrm{R}\,\mathrm{Hom}(A_U, G) \xrightarrow{\sim} \mathrm{R}\,\mathrm{Hom}(A_V, \mathrm{R}i_* G).$$

By the definition of $\underline{D}_V$ (and independently of the fact that K_V is dualizing), one has a canonical arrow

$$(4.7.4) \qquad \mathrm{R}i_* G \overset{\mathbf{L}}{\otimes} \underline{D}_V(\mathrm{R}i_* G) \longrightarrow K_V.$$

From (4.7.2), (4.7.3), and (4.7.4) one obtains a (canonical) arrow

$$(4.7.5) \qquad \mathrm{R}\Gamma(U, G) \overset{\mathbf{L}}{\otimes}_A \mathrm{R}\Gamma(V, i_! G') \longrightarrow \mathrm{R}\,\mathrm{Hom}(A_V, K_V).$$

But $K_V = j^! K_X$, and one has the duality isomorphism (SGAA 3.1.10):

$$(4.7.6) \qquad \mathrm{R}\,\mathrm{Hom}(A_V, K_V) \xrightarrow{\sim} \mathrm{R}\,\mathrm{Hom}(A_{V,X}, K_X).$$

Finally, the exact sequence

$$(4.7.7) \qquad 0 \longrightarrow A_{V,X} \longrightarrow A_X \longrightarrow A_x \longrightarrow 0$$

gives a homomorphism of degree +1:

$$\text{(4.7.8)} \qquad \mathrm{R}\,\mathrm{Hom}(A_{V,X}, K_X) \longrightarrow \mathrm{R}\,\mathrm{Hom}(A_x, K_X) \xrightarrow{\sim} A.$$

Composing (4.7.5), (4.7.6), and (4.7.8), one obtains the announced arrow (4.7.1)'.

(*) (added in 1977) Inexact: in fact it is easy to extend $\overset{\mathbf{L}}{\otimes} : \mathrm{D}^-(A) \times \mathrm{D}^-(A) \to \mathrm{D}^-(A)$ *to* $\overset{\mathbf{L}}{\otimes} : \mathrm{D}^-(A) \times \mathrm{D}(A) \to \mathrm{D}(A)$.

We shall now see that the pairing (4.7.1) is "perfect", i.e. that the arrow (4.7.1)' identifies $\mathrm{R}\Gamma(V, i_!G')[-1]$ with $\underline{D}_x\mathrm{R}\Gamma(U, G)$. Indeed suppose, as is allowed, that

$$G = (ji)^*F,$$

with $F \in \mathrm{ob}\,\mathrm{D}^b_c(X)$. Put $F' = \underline{D}_X(F)$ and $F'_{U,X} = (ji)_!G'$. One has the exact sequence

$$\text{(4.7.9)} \qquad 0 \longrightarrow F'_{U,X} \longrightarrow F' \longrightarrow F'|Y \longrightarrow 0,$$

which gives rise to a distinguished triangle

$$\begin{array}{ccc} & \mathrm{R}\Gamma_x(F'_{U,X}) & \\ {\scriptstyle +1}\nearrow & & \searrow \\ \mathrm{R}\Gamma_x(F'|Y) & \longleftarrow & \mathrm{R}\Gamma_x(F') \end{array} \qquad (b)$$

By definition of $\mathrm{R}\Gamma_x$, one has

$$\mathrm{R}\Gamma_x(F'_{U,X}) = \mathrm{R}\,\mathrm{Hom}(A_x, F'_{U,X});$$

hence, using (4.7.7) and the fact that $(F'_{U,X})_x = \mathrm{R}\Gamma(X, F'_{U,X}) = 0$, one has a canonical isomorphism

$$\mathrm{R}\,\mathrm{Hom}(A_{V,X}, F'_{U,X})[1] \xrightarrow{\sim} \mathrm{R}\Gamma_x(F'_{U,X}).$$

But one has

$$\begin{aligned} \mathrm{R}\,\mathrm{Hom}(A_{V,X}, F'_{U,X}) &= \mathrm{R}\,\mathrm{Hom}(j_!A_V, j_!i_!G') \\ &\xrightarrow{\sim} \mathrm{R}\,\mathrm{Hom}(A_V, i_!G') \qquad \text{by duality (SGAA 3.1.10),} \end{aligned}$$

and hence finally a canonical isomorphism

$$\text{(4.7.10)} \qquad \mathrm{R}\Gamma(V, i_!G')[-1] \xrightarrow{\sim} \mathrm{R}\Gamma_x(F'_{U,X}).$$

On the other hand one has the exact sequence

$$\text{(4.7.11)} \qquad 0 \longrightarrow A_{U,X} \longrightarrow A_X \longrightarrow A_Y \longrightarrow 0,$$

which gives rise to a distinguished triangle

$$\begin{array}{ccc} & \mathrm{R}\Gamma(U, F|U) & \\ {\scriptstyle +1}\swarrow & & \nwarrow \\ \mathrm{R}\Gamma_Y(F) & \longrightarrow & \mathrm{R}\Gamma_X(F) \end{array} \qquad (a)$$

By virtue of (4.7.1) and (4.7.10), one has a natural pairing

$$(4.7.12) \qquad \mathrm{R}\Gamma(U, F|U) \times \mathrm{R}\Gamma_x(F'_{U,X}) \longrightarrow A.$$

By virtue of (4.6.1), one has a perfect pairing

$$(4.7.13) \qquad \mathrm{R}\Gamma_Y(F) \times \mathrm{R}\Gamma_x(F'|Y) \longrightarrow A.$$

Finally, by the ordinary induction formula (1.12 b) (i)), one has a perfect pairing

$$(4.7.14) \qquad \mathrm{R}\Gamma(X, F) \times \mathrm{R}\Gamma_x(F') \longrightarrow A.$$

The reader who has the patience to orient himself in this maze of "canonical arrows" will check that the pairings (4.7.12), (4.7.13), and (4.7.14) are "compatible" with the arrows of the triangles (a) and (b), and consequently that the pairings (4.7.12) and (4.7.1) are perfect.

The pairing of the triangles (a) and (b) gives rise to two exact sequences "transpose to one another":

$$(4.7.15) \qquad \cdots \longrightarrow \mathrm{H}^i_Y(X, F) \longrightarrow \mathrm{H}^i(X, F) \longrightarrow \mathrm{H}^i(U, F) \longrightarrow \cdots$$
$$\cdots \longleftarrow \mathrm{H}^{-i}_x(Y, F'|Y) \longleftarrow \mathrm{H}^{-i}_x(X, F') \longleftarrow \mathrm{H}^{-i-1}(V, F'_{U,V}) \longleftarrow \cdots .$$

In summary, we may state:

Proposition 4.7.16. Let X be a noetherian strictly local scheme, with closed point x. Let Y be a non-empty closed subset of X, let $U = X - Y$, $V = X - x$, and let $i : U \to V$ and $j : V \to X$ be the canonical inclusions. Let K_X be a dualizing complex on X normalized at x (hence giving associated dualizing complexes on V, U, Y). For $G \in \mathrm{ob}\, \mathrm{D}^b_c(U)$, one has a perfect pairing:

$$(*) \qquad \mathrm{R}\Gamma(U, G) \times \mathrm{R}\Gamma(V, i_!G')[-1] \longrightarrow A$$

(where $G' = \underline{D}_U(G)$). If $G = F|U$, where $F \in \mathrm{ob}\, \mathrm{D}^b_c(X)$, one has a canonical isomorphism

$$(**) \qquad \mathrm{R}\Gamma(V, i_!G')[-1] \xrightarrow{\sim} \mathrm{R}\Gamma_x(F'_{U,X})$$

(where $F' = \underline{D}_X(F)$ and $F'_{U,X} = (ji)_!(F'|U) = (ji)_!(G')$), and a perfect pairing between the distinguished triangles

$$\begin{array}{ccc} & \mathrm{R}\Gamma(U, F|U) & \\ {\scriptstyle +1}\swarrow & & \searrow\nwarrow \\ \mathrm{R}\Gamma_Y(F) & \longrightarrow & \mathrm{R}\Gamma(X, F) \end{array} \qquad \text{and} \qquad \begin{array}{ccc} & \mathrm{R}\Gamma_x(F'_{U,X}) & \\ {\scriptstyle +1}\nearrow & & \searrow \\ \mathrm{R}\Gamma_x(F'|Y) & \longleftarrow & \mathrm{R}\Gamma_x(F') \end{array}$$

compatible with the pairing $(*)$ and the isomorphism $(**)$, and giving rise to two exact sequences transpose to one another (4.7.15).

Remark 4.7.17. In the particular case where $Y = \{x\}$, the pairing (4.7.1) is defined under the sole hypothesis that K_X is normalized at x (and not necessarily dualizing), i.e. such that $\mathrm{R}\Gamma_x(K_X) \simeq A$ (the isomorphism being given): the isomorphism (4.7.2) (which used biduality) then reduces to the identity. Since the pairing (4.7.14) is in any case perfect, one sees therefore that local duality on X (in the form (4.2.2)') is equivalent to the "global" duality on $U = X - x$, i.e. to the assertion that the pairing (4.7.1)

$$\mathrm{R}\Gamma(U, G) \times \mathrm{R}\Gamma(U, G')[-1] \longrightarrow A$$

is perfect, or equivalently that the pairings

$$\mathrm{H}^i(U,G)\times\mathrm{H}^{-i-1}(U,G')\longrightarrow A$$

are perfect.

Suppose that one has on X a dualizing complex K_X normalized at x. If X is excellent and U is regular of dimension d (x may therefore be an isolated singularity), one should be able to check that $K_U = K_X|U$ is canonically isomorphic to $(\mu_n)_U^{\otimes d}[2d]$ (this is easily checked, at any rate, if X is the strict localization of a prescheme locally of finite type over a field of characteristic 0). Then local duality on X implies that, for every locally constant constructible A_U-module G, one has perfect pairings:

$$\mathrm{H}^i(U,G)\times\mathrm{H}^{2d-1-i}(U,G^\circ)\longrightarrow A,$$

where $G^\circ = \underline{\mathrm{Hom}}(G,(\mu_n)_U^{\otimes d})$, corresponding formally to Poincaré duality on a scheme of dimension $2d-1$.

5. Local duality on curves

Theorem 5.1. Let X be a noetherian regular prescheme of dimension 1. Suppose that n is prime to the residual characteristics of X. Then the purity theorem is true on X (3.1.4), and the complex A_X is dualizing (1.7).

Proof. Suppose purity has been proved. Since X plainly satisfies condition (reg) (3.1.1), and since condition $(\mathrm{cdloc})_n$ is verified by (SGAA X 2.2), it follows from (3.2.1) that $\dim.q.inj(A_X)=2$. On the other hand, condition (ii) of (1.7) is verified by (3.3.1 b) (i)) (which was proved assuming purity). Hence, by (4.4), we are reduced to proving that A_X is dualizing when X is strictly local. But, to prove purity, which is a local question in a neighborhood of a closed point, one may equally well suppose X strictly local. Finally, we are reduced to proving the theorem when X is strictly local.

Thus suppose that X is strictly local. Let x be its closed point, let $(\pi = \mathrm{car}(k(x)))$, let η be its generic point, and let $U = X - x = \mathrm{Spec}(k(\eta))$. Let $G = \mathrm{Gal}(k(\overline{\eta})/k(\eta))$ be the fundamental group of U. It is known [CL, Chap. IV § 2 Exer. 2] that one has a canonical exact sequence

$$1\longrightarrow P\longrightarrow G\longrightarrow H\longrightarrow 1, \tag{5.1.1}$$

where $H=\prod_{\ell\neq\pi}\mathbb{Z}_\ell(1)$, $\mathbb{Z}_\ell(1)=\varprojlim\mu_{\ell^\nu}$, and P is a pro-π-group. (Of course, H is isomorphic, but not canonically, to $\prod_{\ell\neq\pi}\mathbb{Z}_\ell$.)

It is also known (SGAA VIII 2) that the étale cohomology of U is interpreted as the Galois cohomology of G, sheaves (respectively constructible sheaves) of A_U-modules corresponding to A-modules (respectively finite type A-modules) on which G acts continuously.

This being so, the $\underline{\mathrm{H}}^i_x(A_X)$ are determined by the exact sequence

$$0\longrightarrow\underline{\mathrm{H}}^0_x(A_X)\longrightarrow\mathrm{H}^0(X,A_X)\longrightarrow\mathrm{H}^0(U,A_U)\longrightarrow\underline{\mathrm{H}}^1_x(A_X)\longrightarrow 0, \tag{5.1.2}$$

and the isomorphisms

$$\underline{\mathrm{H}}^i_x(A_X)\xrightarrow{\sim}\mathrm{H}^{i-1}(U,A_U)\qquad\text{for } i\geqslant 2. \tag{5.1.3}$$

But trivially $\mathrm{H}^0(X, A_X) = \mathrm{H}^0(U, A_U) = A$, so $\underline{\mathrm{H}}^0_x(A_X) = \underline{\mathrm{H}}^1_x(A_X) = 0$.

On the other hand, for a Galois G-A-module M, one has the Hochschild–Serre spectral sequence

$$E_2^{pq} = \mathrm{H}^p(H, \mathrm{H}^q(P, M)) \Longrightarrow \mathrm{H}^*(G, M).$$

Since n is prime to π and P is a pro-π-group, one has

$$\mathrm{H}^q(P, M) = 0 \quad \text{for } q \neq 0,$$

hence $E_2^{pq} = 0$ for $q \neq 0$, giving a canonical isomorphism

$$\mathrm{H}^p(G, M) \xrightarrow{\sim} \mathrm{H}^p(H, M^P). \tag{5.1.4}$$

By an analogous argument, one sees moreover that $\mathrm{H}^p(H, N)$ is identified with $\mathrm{H}^p(\widehat{\mathbb{Z}}(1), N)$ when the factor $\widehat{\mathbb{Z}}(1)$ is made to act trivially on N. Thus, finally, with the preceding convention, one has a canonical isomorphism

$$\mathrm{H}^p(G, M) \xrightarrow{\sim} \mathrm{H}^p(\widehat{\mathbb{Z}}(1), M^P). \tag{5.1.5}$$

Now the Galois cohomology of $\widehat{\mathbb{Z}}$ is well known (CG chap. I p. 31): for a G-A-module N, one has

$$\mathrm{H}^i(\widehat{\mathbb{Z}}, N) = 0 \quad \text{for } i \geqslant 2, \qquad \mathrm{H}^0(\widehat{\mathbb{Z}}, N) = N^{\widehat{\mathbb{Z}}}, \qquad \mathrm{H}^1(\widehat{\mathbb{Z}}, N) = N_{\widehat{\mathbb{Z}}}. \tag{5.1.6}$$

From (5.1.3), (5.1.5), and (5.1.6) one immediately deduces that

$$\mathrm{H}^i(U, A_U) = 0 \quad \text{for } i \geqslant 2,$$

and

$$\mathrm{H}^1(U, A_U) \xrightarrow{\sim} A.$$

This last isomorphism is not canonical, since it depends on the choice of an identification of $\widehat{\mathbb{Z}}(1)$ with $\widehat{\mathbb{Z}}$. But, using the Kummer exact sequence, one finds (SGAA XIX 1.3) a canonical isomorphism (given by the "local fundamental class")

$$\mathrm{H}^1(U, \mu_n) \xrightarrow{\sim} A. \tag{5.1.7}$$

Purity is therefore proved.

Let us now prove that A_X is dualizing. By (4.7.17), it is a matter of showing that, for every locally constant constructible A_U-module M, the pairing

$$\mathrm{H}^i(U, M) \times \mathrm{H}^{1-i}(U, \underline{\mathrm{Hom}}(M, A_U)) \longrightarrow \mathrm{H}^1(U, A_U) \xrightarrow{\sim} (\mu_n)_X^{\otimes -1} \tag{5.1.8}$$

is a perfect duality. We shall interpret this pairing in terms of Galois cohomology. We shall use the following elementary lemma.

Lemma 5.1.9. Let $D = \mathrm{Hom}(\ , A)$ denote the Pontrjagin dualizing functor on the category of finite type A-modules. Let M be a finite type A-module on which a group G acts A-linearly.

(i) One has a canonical isomorphism

$$D(M^G) \xrightarrow{\sim} (DM)_G.$$

(ii) If G is a profinite group acting continuously on M, and if G has pro-order prime to n, then the canonical arrow

$$M^G \longrightarrow M_G$$

is an isomorphism.

Proof. By definition one has

$$M^G = \varprojlim_{s\in G} \mathrm{Ker}(M \xrightarrow{s-1} M),$$

hence

$$D(M^G) \xrightarrow{\sim} \varinjlim_{s\in G} \mathrm{Coker}(DM \xrightarrow{s-1} DM) \xrightarrow{\sim} (DM)_G,$$

which proves (i).

Let us prove (ii). Let M' be the A-module defined by the exact sequence

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M_G \longrightarrow 0.$$

One has $\mathrm{H}^1(G, M') = 0$ because G has pro-order prime to n. The exact cohomology sequence therefore implies that the arrow $M^G \to M_G$ is an epimorphism. But, applying the functor D and taking (i) into account, one deduces that it is a monomorphism, which completes the proof.

Applying (5.1.9) to M and P, one finds that $\underline{\mathrm{Hom}}(M, A)^P$ is canonically identified with $\underline{\mathrm{Hom}}(M^P, A)$. If one chooses an isomorphism from $\widehat{\mathbb{Z}}(1)$ to $\widehat{\mathbb{Z}}$, the pairing (5.1.8) is written, taking (5.1.5) into account, as

$$(5.1.8)' \qquad \mathrm{H}^i(\widehat{\mathbb{Z}}, M^P) \times \mathrm{H}^{1-i}(\widehat{\mathbb{Z}}, D(M^P)) \longrightarrow \mathrm{H}^1(\widehat{\mathbb{Z}}, A) \xrightarrow{\sim} A.$$

It follows immediately from (5.1.6) and (5.1.9(i)) that (5.1.8)' is a perfect pairing. This completes the proof of (5.1).

Appendix

by L. Illusie

The preceding theory extends easily to base Rings more general than the constant Ring $\mathbb{Z}/n\mathbb{Z}$. We shall briefly indicate how the theory is written for locally constant base Rings, killed by $n > 0$, and whose geometric fibres are noetherian rings. This is, moreover, only a provisional framework[10]: sooner or later one will have to globalize, by taking as "coefficients" on a prescheme X relative preschemes over the site $(X_{\text{ét}}, \mathbb{Z}/n\mathbb{Z})$.

1. Constructible sheaves

1.1. Let X be a prescheme, and let A_X be a sheaf of rings on X (for the étale topology), locally constant, whose geometric fibres are left noetherian rings. We denote by ${}_AX$ the category of left A_X-Modules, and by $\mathrm{D}({}_AX)$ (or $\mathrm{D}(X)$ if there is no risk of confusion) the corresponding derived category. The notion of a constructible left A_X-Module is defined as in (SGAA IX 2.3), by replacing the expression "locally constant with value of finite presentation" by "of finite presentation as an A_{U_i}-Module".

We denote by $\mathrm{D}_c(X)$ the full subcategory of $\mathrm{D}(X)$ consisting of complexes E such that $\underline{\mathrm{H}}^i(E)$ is a constructible A_X-Module for every i. It is a triangulated subcategory of $\mathrm{D}(X)$.

1.2. Let $E \in \mathrm{ob}\,\mathrm{D}(X)$. We say (cf. Exp. II 3.11) that E is pseudo-coherent if, for every i, $\underline{\mathrm{H}}^i(E)$ is an A_X-Module of finite presentation (or locally constant constructible, if one prefers). We denote by $\mathrm{D}(X)_{\mathrm{coh}}$ (or $\mathrm{D}_{\mathrm{coh}}(X)$) the full subcategory of $\mathrm{D}(X)$ consisting of pseudo-coherent objects. It follows from (SGAA IX 2.1) that this is a triangulated subcategory of $\mathrm{D}_c(X)$.

Proposition 1.3 (dévissage lemma). Let X be a quasi-compact and quasi-separated prescheme (respectively a noetherian prescheme), and let C be a strictly full subcategory of the category $\mathrm{Cons}(X)$ of constructible left A_X-Modules. Suppose that C is stable under extensions. The following conditions are equivalent:

(i) $C = \mathrm{Cons}(X)$;

(ii) C contains the sheaves of the form $i_!(F)$, where $i : Y \to X$ is a sub-prescheme of finite presentation (respectively an integral sub-prescheme), and F is locally constant constructible on Y.

If A_X is constant with value A, a left noetherian ring killed by an integer $n > 0$, the preceding conditions are equivalent to:

(iii) C is stable under direct factors and contains the sheaves of the form $f_*i_!(M_U)$, where $i : U \to Y$ is an open immersion (respectively an open subset of an integral prescheme), $f : Y \to X$ is a finite morphism (respectively finite and such that the generic point of Y is separable over its image), and M_U is a left A_U-Module constant with value a monogenic A-module killed by a prime divisor of n.

[10] According to Grothendieck!

Finally, if X is noetherian and satisfies condition (reg) (I 3.1.1), condition (ii) (respectively (iii)) is equivalent to the analogous condition in which one further assumes Y (respectively U) regular.

Proof. The equivalence of conditions (i) and (ii) is proved as in the case where A_X is constant; see (SGAA IX 2.4 and 2.5).

Suppose that A_X is constant with value A and killed by n, and prove that (iii) implies (ii). Let $E \in \operatorname{ob} \operatorname{Cons}(X)$; we show that $E \in \operatorname{ob} C$. By the equivalence (i)$\Leftrightarrow$(ii), we may suppose that $E = j_! F$, where $j : Z \to X$ is the immersion of a sub-prescheme of finite presentation (respectively an integral one), and F is a constructible locally constant A_Z-Module, which we may even suppose, after a little more dévissage, to be trivialized by an étale covering $g : Z' \to Z$ with group G. The sheaf F is therefore defined by a finite type A-module M on which G acts. If ℓ is a prime divisor of n, the subgroup of ℓ-torsion in M is a sub-G-A-module M_ℓ of M, and

$$M = \bigoplus_\ell M_\ell,$$

where ℓ runs over the set of prime divisors of n. Since C is stable under direct factors, we are reduced to the case where M is ℓ-torsion. Let H be an ℓ-Sylow subgroup of G, and let $h : U = Z'/H \to Z$ be the corresponding intermediate covering. Since the degree of h is prime to ℓ, the "trace method" (SGAA IX 5.1) shows that the adjunction map

$$F \longrightarrow h_* h^*(F)$$

is an isomorphism onto a direct factor; it is therefore enough to prove that $j_! h_* h^*(F) \in \operatorname{ob} C$. By the "Main theorem" (EGA IV 8.12.6), there exists a commutative diagram

$$\begin{array}{ccc} U & \xrightarrow{i} & Y \\ {\scriptstyle h}\downarrow & & \downarrow{\scriptstyle f} \\ Z & \xrightarrow[j]{} & X, \end{array}$$

where i is an open immersion and f is finite. We have

$$j_! h_* h^*(F) \simeq f_* i_! h^*(F).$$

But $h^*(F)$ is defined by M considered as an H-A-module. Thus (iii)$\Rightarrow$(ii) follows from the next lemma.

Lemma 1.3.1. Let A be a left noetherian ring, ℓ a prime number, H a finite ℓ-group, and M a left H-A-module of finite type killed by ℓ^ν ($\nu \geq 1$). There exists a finite filtration of M by sub-H-A-modules such that the successive quotients are monogenic A-modules killed by ℓ, and on which H acts trivially.

Proof. The exact sequence of H-A-modules

$$0 \longrightarrow \ell M \longrightarrow M \longrightarrow M/\ell M \longrightarrow 0$$

reduces, by induction on ν, to the case where M is killed by ℓ. We show that then M has a finite filtration by sub-H-A-modules on whose successive quotients H acts trivially. Arguing by noetherian induction on the set of sub-H-A-modules of M having the stated property, we are reduced to proving that $M \neq 0$ implies $M^H \neq 0$. But the kernel of the augmentation $\mathbb{F}_\ell[H] \to \mathbb{F}_\ell$ is plainly nilpotent, and Nakayama's lemma implies that every nonzero H-$\mathbb{F}_\ell$-module has a nonzero invariant vector.

This proves the assertion. Thus M has a finite filtration whose successive quotients are finite type A-modules killed by ℓ and on which H acts trivially. By noetherian induction one may even arrange for the successive quotients to be monogenic A-modules, completing the proof of (1.3.1).

The last assertion of (1.3) is immediate and left to the reader.

2. Quasi-injective dimension

With the notation of (1.1), one defines, as in (I 1.1 and 1.4), the notions of a quasi-injective A_X-Module and of quasi-injective dimension of an object of $\mathrm{D}(X)$. Propositions (I 1.3, 1.5 and 1.6) extend without change.

It is sometimes convenient to introduce a notion of pointwise quasi-injective dimension. Let $x \in X$ and let $K \in \mathrm{ob}\,\mathrm{D}^+(X)$. We say that K has quasi-injective dimension $\leq N$ at $\bar{x}$ if, for every constructible A_X-Module F, one has

$$\underline{\mathrm{Ext}}^i(F, K)_{\bar{x}} = 0 \qquad \text{for } i > N.$$

The quasi-injective dimension of K at $\bar{x}$, denoted $\dim.\mathrm{q.inj}_{\bar{x}}(K)$, is the greatest lower bound of the N satisfying the preceding condition. Of course,

$$\dim.\mathrm{q.inj}(K) = \sup_{\bar{x}} \dim.\mathrm{q.inj}_{\bar{x}}(K),$$

where $\bar{x}$ runs through the set of geometric points of X.

It is interesting to compare this with the notion of strict topological dimension introduced by Verdier in [1]. We say that $K \in \mathrm{ob}\,\mathrm{D}^+(X)$ has strict topological dimension $\leq N$ at a geometric point $\bar{x}$ of X if, for every sub-prescheme Y of X,

$$\underline{\mathrm{Ext}}^i(A_Y, K)_{\bar{x}} = \underline{\mathrm{H}}^i_Y(K)_{\bar{x}} = 0 \qquad \text{for } i > N.$$

The strict topological dimension of K at $\bar{x}$, denoted $\dim.\mathrm{top}_{\bar{x}}(K)$, is the greatest lower bound of the N satisfying the preceding condition. Whereas quasi-injective dimension depends a priori on the base Ring, strict topological dimension depends only on the underlying complex of abelian sheaves.

One plainly has

$$\dim.\mathrm{top}_{\bar{x}}(K) \leq \dim.\mathrm{q.inj}_{\bar{x}}(K).$$

We shall see below examples where equality holds.

3. Dualizing complexes: definition and formal properties

Keep the preceding notation, but suppose A_X is commutative. The notions of bidualizing pair and dualizing complex are defined as in (I 1.7). The statements (I 1.9, 1.11, 1.14) remain valid without modification. The statements (I 1.12, 1.13, 1.15) are also valid, but on condition that A be killed by an integer $n > 0$ prime to the residual characteristics of Y. Finally, the uniqueness theorem (I 2.1) is valid provided one assumes $\mathrm{Spec}(A_{\bar{x}})$ connected for every geometric point $\bar{x}$ of X.

4. Absolute purity

Return to the situation of absolute cohomological purity (I 3.1.4). Let X be a locally noetherian regular prescheme, let $n > 0$ be an integer prime to the residual characteristics of X, and let $i : Y \to X$ be a regular sub-prescheme of codimension $d > 0$ at every point. To say that the pair (Y, X) satisfies absolute cohomological purity means, recall, that the "local fundamental class" homomorphism (SGA $4^{1/2}$ Cycle 2.2)

$$(\mu_n^{\otimes -d})_Y[-2d] \longrightarrow \mathrm{R}i^!(\mathbb{Z}/n\mathbb{Z})_X \tag{4.1}$$

is an isomorphism.

Now put on X a sheaf of rings A_X killed by n. For the moment set $G = (\mathbb{Z}/n\mathbb{Z})_X$. Then, for every $F \in \mathrm{ob}\,\mathrm{D}_A^+(X)$, one can define a canonical arrow in $\mathrm{D}_A^+(X)$:

$$i^*(F) \otimes^L_{\mathbb{Z}/n\mathbb{Z}} \mathrm{R}i^!(G) \longrightarrow \mathrm{R}i^!(F \otimes^L_{\mathbb{Z}/n\mathbb{Z}} G). \tag{4.2}$$

Indeed, by duality (SGAA XVIII 3.1.6), this is equivalent to defining an arrow

$$i_!(i^*(F) \otimes^L_{\mathbb{Z}/n\mathbb{Z}} \mathrm{R}i^!(G)) \longrightarrow F \otimes^L_{\mathbb{Z}/n\mathbb{Z}} G;$$

we take this to be the composite of the Künneth arrow (SGAA XVII 5.4.2.2)

$$i_!(i^*(F) \otimes^L_{\mathbb{Z}/n\mathbb{Z}} \mathrm{R}i^!(G)) \longrightarrow F \otimes^L_{\mathbb{Z}/n\mathbb{Z}} i_!\mathrm{R}i^!(G),$$

and the arrow deduced from the trace homomorphism (SGAA XVIII 3.1.6)

$$F \otimes^L_{\mathbb{Z}/n\mathbb{Z}} i_!\mathrm{R}i^!(G) \longrightarrow F \otimes^L_{\mathbb{Z}/n\mathbb{Z}} G.$$

Notice that in the definition of (4.2) only the fact that G and $\mathrm{R}i^!(G)$ have finite Tor-dimension over $\mathbb{Z}/n\mathbb{Z}$ was used. Suppose on the other hand that the functor $i^!$ has finite cohomological dimension on the category of $(\mathbb{Z}/n\mathbb{Z})_X$-Modules: this is the case, for example, if X is of finite type over a field (SGAA XIV 3.1), or more generally if X is excellent of equal characteristic (SGAA XIX 6.1) when resolution of singularities is available, or again if X is of finite type over $\mathrm{Spec}(\mathbb{Z})$ (SGAA X 6). Then the arrow (4.2) is defined for all $F \in \mathrm{ob}\,\mathrm{D}({}_AX)$.

Composing (4.1) and (4.2), one obtains, for $F \in \mathrm{ob}\,\mathrm{D}_A^+(X)$, a canonical arrow

$$i^*(F) \otimes^L_{\mathbb{Z}/n\mathbb{Z}} (\mu_n^{\otimes -d})_Y[-2d] \longrightarrow \mathrm{R}i^!(F). \tag{4.3}$$

Assume that A_X is locally constant, and let $F \in \mathrm{ob}\,\mathrm{D}_A^+(X)$ be such that every $\underline{\mathrm{H}}^i(F)$ is a locally constant A_X-Module. Then, if $i^!$ has finite cohomological dimension, the arrow (4.2), and hence the arrow (4.3) if (Y, X) satisfies purity, is an isomorphism.

Indeed, by dévissage, one first reduces to the case where F is concentrated in degree zero. Since the question is local, one may suppose X affine and A_X and F constant. Resolving F on the left by free A_X-Modules and applying the hypothesis that $i^!$ has finite cohomological dimension, one reduces to the case where F is free. By an immediate passage to the limit, one reduces to F free of finite type, and finally to $F = A_X$. It is therefore enough to prove the assertion when $A_X = (\mathbb{Z}/n\mathbb{Z})_X$. But the preceding dévissage reduces to $F = (\mathbb{Z}/n\mathbb{Z})_X$, and in that case (4.2) is the identity.

Definition 4.4. Given the Ring A_X (locally constant and killed by n), we shall say that the pair (Y, X) satisfies cohomological purity in the strong sense if, for every $F \in \mathrm{ob}\,\mathrm{D}_A^+(X)$ such that the $\underline{\mathrm{H}}^i(F)$ are locally constant, the canonical arrow (4.3) is an isomorphism.

We shall say that the purity theorem is true in the strong sense on X if, locally for the étale topology, every pair (Y, X) as above satisfies purity in the strong sense. From what has been shown, for (Y, X) to satisfy purity in the strong sense it is enough that (Y, X) satisfy ordinary purity (I 3.1.) and that the functor $i^!$ have finite cohomological dimension.

5. Bound for quasi-injective dimension

Proposition 5.1. Let X be a locally noetherian regular prescheme, equipped with a locally constant sheaf of rings A_X, killed by an integer $n > 0$ prime to the residual characteristics of X, whose geometric fibres are left noetherian rings. Suppose that X satisfies conditions (reg) (I 3.1.1) and $(\mathrm{cdloc})_n$ (I 3.1.3), and that the purity theorem in the strong sense is true on X (4.4) (conditions all satisfied if X is smooth over a perfect field, or if X is excellent of characteristic zero).

Let $F \in \mathrm{ob}\, \mathrm{D}_A^+(X)$ be such that the $\underline{\mathrm{H}}^i(F)$ are locally constant, and let x be a point of X such that $F_{\bar{x}} \neq 0$ and $\dim .\mathrm{inj}_{A_{\bar{x}}}(F_{\bar{x}}) < +\infty$. Then

$$\dim .\mathrm{q.inj}_{\bar{x}}(F) = 2\dim(\mathcal{O}_{X,x}) + \dim .\mathrm{inj}(F_{\bar{x}}),$$

with the notation of no. 2.

Proof. One merely repeats step by step the proof of (I 3.2.1). First show the inequality

$$\dim .\mathrm{q.inj}_{\bar{x}}(F) \leq 2\dim(\mathcal{O}_{X,x}) + \dim .\mathrm{inj}(F_{\bar{x}}) = N,$$

that is, the relation

$$\underline{\mathrm{Ext}}^i(E, F)_{\bar{x}} = 0 \quad \text{for } i > N \text{ and every constructible } A_X\text{-Module } E. \tag{*}$$

Since the question is local, by dévissage (1.3) one may restrict to checking $(*)$ for $E = i_!(M)$, where $i : Y \to X$ is an integral regular sub-prescheme closed in an open $D(f)$ (with $f \in \Gamma(X, \mathcal{O}_X)$), of codimension d at every point of $D(f)$, and M is a locally constant constructible A_Y-Module ($A_Y = i^* A_X$).

Now there is the duality isomorphism (SGAA XVIII)

$$\mathrm{R}\underline{\mathrm{Hom}}(i_!(M), F) \simeq \mathrm{R}i_* \mathrm{R}\underline{\mathrm{Hom}}(M, \mathrm{R}i^! F).$$

By the purity theorem, there is also the isomorphism (4.3)

$$i^*(F) \otimes^L_{\mathbb{Z}/n\mathbb{Z}} (\mu_n^{\otimes -d})_Y[-2d] \xrightarrow{\sim} \mathrm{R}i^!(F).$$

Let $\bar{y}$ be a geometric point of Y. Since M is locally constant constructible, one has canonically

$$\mathrm{R}\underline{\mathrm{Hom}}(M, \mathrm{R}i^! F)_{\bar{y}} \simeq \mathrm{R}\underline{\mathrm{Hom}}(M_{\bar{y}}, (\mathrm{R}i^! F)_{\bar{y}}),$$

hence, by (4.3),

$$\mathrm{R}\underline{\mathrm{Hom}}(M, \mathrm{R}i^! F)_{\bar{y}} \simeq \mathrm{R}\underline{\mathrm{Hom}}(M_{\bar{y}}, F_{\bar{y}})[-2d].$$

After replacing X by a connected neighbourhood of x, one has $F_{\bar{x}} \simeq F_{\bar{y}}$ and $A_{\bar{x}} \simeq A_{\bar{y}}$, since A_X and the $\underline{\mathrm{H}}^i(F)$ are locally constant. Thus

$$\underline{\mathrm{Ext}}^i(M_{\bar{y}}, F_{\bar{y}}) = 0 \quad \text{for } i > \dim .\mathrm{inj}(F_{\bar{x}}),$$

and hence

$$\underline{\mathrm{Ext}}^q(M, \mathrm{R}i^!F) = 0 \quad \text{for } q > 2d + \dim.\mathrm{inj}(F_{\bar{x}}).$$

Set $G = \mathrm{R}\underline{\mathrm{Hom}}(M, \mathrm{R}i^!F)$ and compute $\mathrm{R}i_*(G)_{\bar{x}}$. Introduce, as in (I 3.2.1), the schematic closure Z of Y in X, giving a cartesian diagram of immersions

$$\begin{array}{ccc} Y & \longrightarrow & D(f) \\ {\scriptstyle j}\downarrow & & \downarrow \\ Z & \xrightarrow[k]{} & X. \end{array}$$

Then $\mathrm{R}i_*(G) \simeq k_*\mathrm{R}j_*(G)$. Assume of course that $x \in Z$, since otherwise $\mathrm{R}i_*(G) = 0$. Let $\bar{Z} = \mathrm{Spec}(\mathcal{O}_{Z,\bar{x}})$ be the strict localization of Z at $\bar{x}$, let $\bar{f}$ be the image of f in $\mathcal{O}_{Z,\bar{x}}$, let $\bar{Y} = \bar{Z} \times_Z Y = \bar{Z} \cap D(\bar{f})$, and let $\bar{G}$ be the inverse image of G on $\bar{Y}$. By (SGAA VIII 5.2),

$$\mathrm{R}i_*(G)_{\bar{x}} = \mathrm{R}j_*(G)_{\bar{x}} \simeq \mathrm{R}\Gamma(\bar{Y}, \bar{G}).$$

Condition $(\mathrm{cdloc})_n$ therefore implies, by a spectral sequence argument, that

$$R^p i_*(G)_{\bar{x}} = 0 \quad \text{for } p > 2d + \dim.\mathrm{inj}(F_{\bar{x}}) + \dim(\mathcal{O}_{Z,x}).$$

But (cf. the proof of I 3.2.1)

$$\dim(\mathcal{O}_{Z,x}) = \dim(\mathcal{O}_{X,x}) - d \geq 0,$$

so

$$R^p i_*(G)_{\bar{x}} = 0 \quad \text{for } p > d + \dim(\mathcal{O}_{X,x}) + \dim.\mathrm{inj}(F_{\bar{x}}),$$

and a fortiori for $p > 2\dim(\mathcal{O}_{X,x}) + \dim.\mathrm{inj}(F_{\bar{x}})$. This proves $(*)$.

It remains to prove that the bound $(*)$ is the best possible. Put $f = \dim.\mathrm{inj}(F_{\bar{x}})$, and choose a finite type $A_{\bar{x}}$-Module M' such that

$$\underline{\mathrm{Ext}}^f(M', F_{\bar{x}}) \neq 0.$$

Let Z be the integral closed sub-prescheme of X which is the closure of x, and let $Y = U \cap Z$ be a regular open subset of Z containing x and of codimension $d = \dim(\mathcal{O}_{X,x})$ at every point. After possibly shrinking Y, there exists a locally constant constructible A_Y-Module M such that $M_{\bar{x}} = M'$. Applying the purity theorem, one finds

$$\underline{\mathrm{Ext}}^{2d+f}(M, F|U)_{\bar{x}} \simeq \underline{\mathrm{Ext}}^f(M', F_{\bar{x}}) \neq 0,$$

which completes the proof.

If F is an A_X-Module such that $F_{\bar{x}}$ is injective, then in the last part of the proof one may take $M = A_Y$; hence:

Corollary 5.1.1. Under the hypotheses of (5.1), suppose that F is a locally constant A_X-Module such that $F_{\bar{x}}$ is injective. Then

$$\dim.\mathrm{q.inj}_{\bar{x}}(F) = \dim.\mathrm{top}_{\bar{x}}(F) = 2\dim(\mathcal{O}_{X,x}),$$

with the notation of no. 2.

Remarks 5.1.2. a) With the notation of (5.1), if $F_{\bar{x}} = 0$, then $F = 0$ in a neighbourhood of x, hence $\mathrm{R}\underline{\mathrm{Hom}}(E, F)_{\bar{x}} = 0$ for all $E \in \mathrm{ob}\,\mathrm{D}^-(X)$.

b) If $\dim.\mathrm{inj}(F_{\bar{x}}) = +\infty$, then $\dim.\mathrm{q.inj}_{\bar{x}}(F) = +\infty$; indeed, for every p there exists a finite type $A_{\bar{x}}$-module M' such that $\underline{\mathrm{Ext}}^p(M', F_{\bar{x}}) \neq 0$, hence a constructible A_X-Module M, locally constant in a neighbourhood of x, such that $\underline{\mathrm{Ext}}^p(M, F)_{\bar{x}} \neq 0$.

6. Constructibility of $\mathrm{R}\underline{\mathrm{Hom}}$

The equivalence of conditions a) of (I 3.3.1) remains valid when the Ring $(\mathbb{Z}/n\mathbb{Z})_X$ is replaced by a commutative Ring, locally constant, whose geometric fibres are noetherian rings: nothing has to be changed in the proof.

The preceding conditions are verified when one has resolution of singularities and purity in the strong sense (4.4), in particular if X has dimension ≤ 1, or if X is excellent of characteristic zero, or locally of finite type over a field and of dimension ≤ 2.

7. Existence of dualizing complexes

In this number, X denotes a prescheme equipped with a commutative sheaf of rings A_X, locally constant, whose geometric fibres are noetherian rings.

Lemma 7.1. If $F \in \mathrm{ob}\,\mathrm{D}^-_{\mathrm{coh}}(X)$ and $G \in \mathrm{ob}\,\mathrm{D}^+_{\mathrm{coh}}(X)$, then $\mathrm{R}\underline{\mathrm{Hom}}(F,G) \in \mathrm{ob}\,\mathrm{D}^+_{\mathrm{coh}}(X)$ (notation of (1.2)).

Proof. This is standard. One reduces, by a spectral sequence, to F and G concentrated in degree zero, and then argues as in (EGA 0_{III} 12.3.3).

Lemma 7.2. Let $g : X' \to X$ be a morphism of preschemes, and endow X' with the sheaf of rings $A_{X'} = g^*(A_X)$. Then, for $F \in \mathrm{ob}\,\mathrm{D}^-_{\mathrm{coh}}(X)$ and $G \in \mathrm{ob}\,\mathrm{D}^+(X)$, the canonical map

$$g^*\mathrm{R}\underline{\mathrm{Hom}}(F,G) \longrightarrow \mathrm{R}\underline{\mathrm{Hom}}(g^*F, g^*G)$$

is an isomorphism.

Proof. This too is standard: one reduces by dévissage to $F = A_X$ (cf. EGA 0_{III} 12.3.5).

Remark 7.2.1. The preceding lemmas are special cases of more general statements appearing in (SGA 6 I).

Lemma 7.3. Suppose X is quasi-compact, and let $K \in \mathrm{ob}\,\mathrm{D}^+_{\mathrm{coh}}(X)$ be such that, for every geometric point $\bar{x}$ of X, $K_{\bar{x}}$ is a dualizing complex in the sense of [H] V 2.1. Then, for every $F \in \mathrm{ob}\,\mathrm{D}^b_{\mathrm{coh}}(X)$, one has $\mathrm{R}\underline{\mathrm{Hom}}(F,K) \in \mathrm{ob}\,\mathrm{D}^b_{\mathrm{coh}}(X)$, and F is reflexive relative to K.

Proof. It suffices, of course, to check this for F concentrated in degree zero. By (7.1), $\mathrm{R}\underline{\mathrm{Hom}}(F,K) \in \mathrm{ob}\,\mathrm{D}^+_{\mathrm{coh}}(X)$. To prove boundedness, let $\bar{x}$ be a geometric point of X. By (7.2),

$$\mathrm{R}\underline{\mathrm{Hom}}(F,K)_{\bar{x}} \simeq \mathrm{R}\underline{\mathrm{Hom}}(F_{\bar{x}}, K_{\bar{x}}).$$

Putting $\dim.\mathrm{inj}(K_{\bar{x}}) = N(\bar{x})$, one obtains

$$\underline{\mathrm{Ext}}^i(F,K)_{\bar{x}} = 0 \quad \text{for } i > N(\bar{x}).$$

Since the sheaves $\underline{\mathrm{Ext}}^i(F,K)$ are locally constant, there is an open neighbourhood U of x such that $\underline{\mathrm{Ext}}^i(F,K)|U = 0$ for $i > N(\bar{x})$, and quasi-compactness of X gives the assertion. It remains to check that the canonical arrow

$$F \longrightarrow \mathrm{R}\underline{\mathrm{Hom}}(\mathrm{R}\underline{\mathrm{Hom}}(F,K),K)$$

is an isomorphism. It is enough to evaluate at a geometric point $\bar{x}$ of X. In the commutative

diagram

$$\begin{array}{ccc} F_{\bar{x}} & \longrightarrow & \mathrm{R}\underline{\mathrm{Hom}}(\mathrm{R}\underline{\mathrm{Hom}}(F,K),K)_{\bar{x}} \\ {\scriptstyle \mathrm{Id}}\downarrow & & \downarrow \\ F_{\bar{x}} & \longrightarrow & \mathrm{R}\underline{\mathrm{Hom}}(\mathrm{R}\underline{\mathrm{Hom}}(F_{\bar{x}},K_{\bar{x}}),K_{\bar{x}}), \end{array}$$

the right vertical arrow is an isomorphism by (7.2), and the bottom horizontal arrow is an isomorphism because $K_{\bar{x}}$ is dualizing; hence the top horizontal arrow is an isomorphism, q.e.d.

Lemma 7.4. Suppose X is a noetherian regular prescheme, A_X is killed by an integer $n > 0$ prime to the residual characteristics of X, and the purity theorem in the strong sense (4.4) is true on X.

Let D be a divisor with normal crossings on X (I 3.1.5 a)), and denote by $j : Y = V(D) \to X$ and $i : X - Y = U \to X$ the canonical inclusions. Let $K \in \mathrm{ob}\,\mathrm{D}^{+}_{\mathrm{coh}}(X)$ be such that, for every geometric point $\bar{x}$ of X, $K_{\bar{x}}$ is a dualizing complex for the ring $A_{\bar{x}}$ (in the sense of [H] V 2.1). Then, for every $E \in \mathrm{ob}\,\mathrm{D}^{b}_{\mathrm{coh}}(X)$, one has $\mathrm{R}\underline{\mathrm{Hom}}(i_!i^*(E),K) \in \mathrm{ob}\,\mathrm{D}^{b}_{c}(X)$, and the pair $(i_!i^*(E),K)$ is bidualizing.

Proof. We may suppose E is concentrated in degree zero, i.e. a locally constant constructible A_X-Module. Since the question is local on X for the étale topology, we may suppose that (a) A_X is constant with value A, and E is constant with value E; and (b) D has strict normal crossings, say $D = \sum_{i\in I} \mathrm{div}(s_i)$ with $s_i \in \Gamma(X,\mathcal{O}_X)$.

Argue by induction on $p = \mathrm{card}(I)$. For $p = 0$, the assertions follow from (7.3). Suppose $I = \{1,\dots,p\}$, put $Y_i = V(s_i)$, $Y' = V(\sum_{1\le i\le p-1} \mathrm{div}(s_i))$, and $U' = X - Y'$. We get a cartesian diagram of immersions

$$\begin{array}{ccccc} \varnothing & \longrightarrow & U'\cap Y_p & \xrightarrow{i'_p} & Y_p \\ \downarrow & & {\scriptstyle j'_p}\downarrow & & \downarrow{\scriptstyle j_p} \\ U & \longrightarrow & U' & \xrightarrow[i']{} & X. \end{array}$$

Consider the exact sequence

$$0 \longrightarrow E_{U,X} \longrightarrow E_{U',X} \longrightarrow E_{U'\cap Y_p,X} \longrightarrow 0.$$

By the induction hypothesis the theorem is true for $(E_{U',X},K)$. For fixed K, the F such that $\mathrm{R}\underline{\mathrm{Hom}}(F,K) \in \mathrm{ob}\,\mathrm{D}^{b}_{c}(X)$ and (F,K) is bidualizing form a triangulated subcategory of $\mathrm{D}_c(X)$; hence we are reduced to the case $F = E_{U'\cap Y_p,X}$. But

$$E_{U'\cap Y_p,X} = j_{p*}i'_{p!}(E_{U'\cap Y_p}),$$

and, by (I 1.13), it is equivalent to prove the theorem for $(i'_{p!}(E_{U'\cap Y_p}),\mathrm{R}j^{!}_{p}(K))$ on Y_p. By purity, however,

$$\mathrm{R}j^{!}_{p}(K) \simeq j^{*}_{p}(K) \otimes^{L}_{\mathbb{Z}/n\mathbb{Z}} (\mu_n)^{\otimes -1}_{Y_p}[-2].$$

Thus $\mathrm{R}j^{!}_{p}(K) \in \mathrm{ob}\,\mathrm{D}^{+}_{\mathrm{coh}}(Y_p)$ and, for every geometric point $\bar{y}$ of Y_p, $(\mathrm{R}j^{!}_{p}(K))_{\bar{y}}$ is dualizing. The induction hypothesis then applies.

Theorem 7.5. Assume the following: X is a noetherian regular prescheme; A_X is killed by an integer $n > 0$ prime to the residual characteristics of X; X is strongly desingularizable (I 3.1.5), satisfies conditions (reg) (I 3.1.1) and $(\mathrm{cdloc})_n$ (I 3.1.3); and the purity theorem in the strong sense (4.4) is true on every prescheme smooth over X (conditions satisfied if X is excellent of characteristic zero, or of dimension ≤ 2 and smooth over a perfect field).

Then, if $K \in \mathrm{ob}\, \mathrm{D}^+_{\mathrm{coh}}(X)$ is such that $K_{\bar{x}}$ is dualizing (in the sense of [H] V 2.1) for every geometric point $\bar{x}$ of X, the complex K is dualizing.

Proof. We must show that K satisfies conditions (i) to (iii) of (I 1.7). For every geometric point $\bar{x}$ of X, $K_{\bar{x}}$ has finite injective dimension, and since $K \in \mathrm{ob}\, \mathrm{D}^+_{\mathrm{coh}}(X)$, the function $x \mapsto \dim .\mathrm{inj}(K_{\bar{x}})$ is locally constant; it is therefore bounded because X is noetherian. It follows from (5.1) that K has finite quasi-injective dimension.

By what was seen in no. 6, condition (ii) of loc. cit. is also satisfied.

It remains to prove condition (iii), i.e. that every $F \in \mathrm{ob}\, \mathrm{D}^b_c(X)$ is reflexive relative to K. By dévissage we may suppose F is concentrated in degree zero. Since the question is local on X for the étale topology, we may suppose A_X constant with value A. Dévissage (1.3) then reduces us to $F = f_* i_!(E_U)$, where $f : Y \to X$ is finite, Y is integral with generic point separable over its image, $i : U \to Y$ is a nonempty regular open, and E_U is an A_U-Module constant with value a finite type A-module E. Since X is strongly desingularizable, there exists (I 3.1.5) a projective birational morphism $h : Y' \to Y$ such that Y' is regular, h induces an isomorphism $h^{-1}(U) \to U$, and $h^{-1}(U)$ is the complement of a normal crossings divisor in Y'. Identifying $h^{-1}(U)$ with U via h, we have a commutative diagram

$$\begin{array}{ccccc} & & Y' & & \\ & \overset{i'}{\nearrow} & \downarrow{\scriptstyle h} & \overset{g}{\searrow} & \\ U & \xrightarrow[i]{} & Y & \xrightarrow[f]{} & X. \end{array}$$

Consequently,

$$f_* i_!(E_U) \simeq f_* \mathrm{R}h_* i'_!(E_U) \simeq \mathrm{R}g_* i'_!(E_U) \simeq \mathrm{R}g_* i'_! i'^*(E_{Y'}).$$

By (I 1.13), it is enough to prove biduality for the pair $(i'_! i'^*(E_{Y'}), \mathrm{R}g^!(K))$. But, locally embedding Y' into a prescheme X' smooth over X and applying strong purity on X' (4.4), one finds that $\mathrm{R}g^!(K)$ is locally isomorphic, up to degree shift, to $g^*(K)$. Hence $\mathrm{R}g^!(K) \in \mathrm{ob}\, \mathrm{D}^+_{\mathrm{coh}}(Y')$ and $\mathrm{R}g^!(K)_{\bar{x}}$ is dualizing for every geometric point $\bar{x}$ of Y'. It remains only to apply (7.4).

The preceding proof also shows that $\mathrm{R}\underline{\mathrm{Hom}}(F, K) \in \mathrm{ob}\, \mathrm{D}^b_c(X)$ (using the finiteness theorem for a proper morphism (SGAA XIV)), which will reassure the reader who did not trust the spiel of no. 6.

This completes the proof.

SGA 5 — Exposé III

LEFSCHETZ FORMULA

by A. Grothendieck, written up by L. Illusie

In this exposé we prove the Lefschetz formula in étale cohomology, for correspondences between complexes of sheaves, in Verdier's formulation (cf. [18]). In an earlier version, distributed by the IHES about ten years ago, the formula was stated, under resolution hypotheses, but the required compatibilities were not proved. Deligne's finiteness theorems (SGA $4^{1/2}$, Finiteness) made it possible to dispense with these hypotheses, provided one works with schemes separated and of finite type over a field. As for the compatibilities, the editor has verified them (painfully).

Let us say at once that the Lefschetz formula in question here, just like the trace formula for constant coefficients (SGA $4^{1/2}$, Cycle), which it generalizes, is essentially trivial: it only translates certain compatibilities in the formalism of duality. Roughly speaking, it says that, under certain conditions, the trace of an endomorphism of a hypercohomology complex $R\Gamma(X, L)$, where L is a complex of sheaves on X, can be calculated as an "integral" of certain cohomology classes on $X \times X$. In practice, the endomorphisms one considers are associated with correspondences $C \subset X \times X$, and the classes recovered on the product have support in $C \cap \Delta$, where Δ is the diagonal; these classes are "local in nature" in a neighbourhood of the fixed points, which in principle facilitates their calculation. See 4.2 and 4.7 for precise statements. In fact, the calculation of these "local" classes in terms of more comprehensible invariants, without which the present formula would have no interest, has so far been undertaken only in very special situations (see 4.10, 4.11, and the following exposé, where in particular the case of the Frobenius correspondence on a curve is treated).

For lack of a good derived category of ℓ-adic sheaves (Jouanolou's thesis unfortunately not having been published), we work systematically with torsion coefficients (prime to the residual characteristics). Despite minor technical difficulties in the definition of traces, this point of view in fact leads to finer formulae, also more manageable insofar as, for the calculation of local terms, one wants to trivialize the sheaves involved by coverings (see notably (SGA $4^{1/2}$, Report), III B, and XII).

In no. 1, we fix the notation and recall various Künneth formulae from (SGA $4^{1/2}$, Finiteness), which play an essential role in what follows. We also introduce a certain number of fibred and cofibred categories, whose consideration later facilitates certain verifications of compatibilities. No. 2, which is very technical, may be skipped on first reading. Its main result (2.5) expresses a compatibility between external tensor product of RHom, direct image, and base change. In no. 3, we define cohomological correspondences between complexes, and show how they act on hypercohomology; the result quoted above makes it possible to describe this action in several equivalent ways. The core of the exposé is no. 4, where Verdier's pairing between cohomological correspondences is defined and the Lefschetz formula is proved, in a relative situation appreciably more general than the one usually considered, with a view to later applications to computations of local terms. We give the most evident corollaries for correspondences with constant coefficients. In no. 5, we indicate rapidly how to generalize to correspondences between complexes certain usual constructions on correspondences with constant coefficients (cf. [12]), such as passage to the dual, composition, and external tensor product. Most of the verifications, analogous to those in the preceding numbers, have been omitted. Finally, in the appendix, we paraphrase the preceding theory in the context of coherent sheaves, using the formalism of duality of [8]. Here one may work over any noetherian base S, provided that, when necessary, one imposes hypotheses of properness, finite tor-dimension, and tor-independence on the S-schemes considered. We show that the very general Lefschetz formula thereby obtained contains as a special case the Woods Hole formula [1], and we point out some applications.

2 Notation and recalls of Künneth formulae

1.1

We denote by S the spectrum of a field. Unless otherwise stated, the S-schemes considered in what follows will be S-schemes separated and of finite type.

We denote by A a commutative noetherian ring, annihilated by an integer invertible on S. If X is an S-scheme, we denote by $D(X) = D(X, A)$ the derived category of complexes of A-modules on X (for the étale topology), and by $D_{\mathrm{ctf}}(X)$ the full subcategory consisting of complexes of finite tor-dimension, with constructible cohomology. The category $D_{\mathrm{ctf}}(X)$ is a triangulated subcategory of $D(X)$. If $E, F \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$, it follows readily from the definitions that $E \otimes^L F \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$. According to (SGA $4^{1/2}$, Finiteness Theorem 1.6, 1.7), one also has $\mathrm{RHom}(E, F) \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$.

1.2

Let $f : X \to Y$ be an S-morphism. One has trivially

$$f^* D_{\mathrm{ctf}}(Y) \subset D_{\mathrm{ctf}}(X),$$

and, by (loc. cit.),

$$Rf_* D_{\mathrm{ctf}}(X) \subset D_{\mathrm{ctf}}(Y), \qquad Rf_! D_{\mathrm{ctf}}(X) \subset D_{\mathrm{ctf}}(Y), \qquad Rf^! D_{\mathrm{ctf}}(Y) \subset D_{\mathrm{ctf}}(X),$$

(the inclusion relative to $Rf_!$ uses only the finiteness theorem for proper morphisms (SGA 4 XIV) and the sorites (SGA 4 XVII 5.2.11), and hence holds more generally for every compactifiable morphism whose fibres have bounded dimension). In what follows, we shall sometimes write f_*, $f_!$, $f^!$ instead of Rf_*, $Rf_!$, $Rf^!$; the hypotheses of 1.1 imply that these functors are defined on the whole derived category.

1.3

For $f : X \to S$, we shall put

$$K_X = f^! A,$$

and shall denote by D_X (or D) the functor $\mathrm{RHom}(-, K_X)$. According to (SGA $4^{1/2}$, Finiteness Theorem 4.3), the complex K_X is dualizing: for $E \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$, one has canonically

$$E \xrightarrow{\sim} DDE.$$

1.4

Let $f : X \to Y$ be an S-morphism, $L \in \operatorname{ob} D(X)$, $M \in \operatorname{ob} D(Y)$. We put

$$\operatorname{Hom}_f^{(1)}(L, M) = \operatorname{Hom}(f^*M, L) \quad (\simeq \operatorname{Hom}(M, f_*L)),$$

$$\operatorname{Hom}_f^{(2)}(L, M) = \operatorname{Hom}(L, f^*M),$$

$$\operatorname{Hom}_f^{(3)}(L, M) = \operatorname{Hom}(f_!L, M) \quad (\overset{\text{(SGA 4 XVIII 3.1.5)}}{\simeq} \operatorname{Hom}(L, f^!M)),$$

$$\operatorname{Hom}_f^{(4)}(L, M) = \operatorname{Hom}(f^!M, L).$$

The elements of $\operatorname{Hom}_f^{(i)}(L, M)$ will be called *arrows of type i from L to M over f* (or f-arrows of type i from L to M). The transitivity isomorphisms for the functors f^*, f_*, $f_!$, $f^!$ allow one to compose arrows of type i for fixed i, and one thus obtains certain fibred or cofibred categories over the category of S-schemes: for example, for $i = 1$ (resp. $i = 3$) one obtains the fibred and cofibred category considered in (SGA 4 XVII 4.1.3) (resp. (SGA 4 XVIII 3.1.13)), whose fibre over X is the category opposite to $D(X)$ (resp. $D(X)$).

1.5

Let, for $i = 1, 2$, X_i be an S-scheme, $X = X_1 \times_S X_2$, and $L_i \in \operatorname{ob} D^-(X_i)$. We put

$$L_1 \otimes_S^L L_2 = \operatorname{pr}_1^* L_1 \otimes^L \operatorname{pr}_2^* L_2,$$

where $\operatorname{pr}_i : X \to X_i$ is the canonical projection.

1.6

Let, for $i = 1, 2$, $f_i : X_i \to Y_i$ be an S-morphism,

$$f = f_1 \times_S f_2 : X = X_1 \times_S X_2 \to Y = Y_1 \times_S Y_2,$$

$L_i \in \operatorname{ob} D^-(X_i)$, $M_i \in \operatorname{ob} D^-(Y_i)$. The evident canonical isomorphism

$$f_1^*M_1 \otimes_S^L f_2^*M_2 \xrightarrow{\sim} f^*(M_1 \otimes_S^L M_2) \tag{1.6.1}$$

allows one to define, for $u_i \in \operatorname{Hom}_{f_i}^{(1)}(L_i, M_i)$ (resp. $\operatorname{Hom}_{f_i}^{(2)}(L_i, M_i)$),

$$u_1 \otimes_S^L u_2 \in \operatorname{Hom}_f^{(1)}(L, M) \quad (\text{resp. } \operatorname{Hom}_f^{(2)}(L, M)), \tag{1.6.2}$$

where $L = L_1 \otimes_S^L L_2$, $M = M_1 \otimes_S^L M_2$. If u_i, v_i are composable, one has

$$(v_1u_1) \otimes_S^L (v_2u_2) = (v_1 \otimes_S^L v_2)(u_1 \otimes_S^L u_2). \tag{1.6.3}$$

Taking $M_i = f_{i*}L_i$, and u_i of type 1, given by the identity of $f_{i*}L_i$, 1.6.2 gives a *Künneth arrow* (cf. SGA 4 XVII 5.4.1.4)

$$f_{1*}L_1 \otimes_S^L f_{2*}L_2 \longrightarrow f_*(L_1 \otimes_S^L L_2). \tag{1.6.4}$$

According to (SGA $4^{1/2}$, Finiteness Theorem 1.9), 1.6.4 is an isomorphism: by 1.6.3 one is indeed reduced to the case where $X_2 = Y_2$, $f_2 = 1$, and one applies (loc. cit. App.). When f_1 and f_2 are proper, it is not necessary to invoke (loc. cit.): 1.6.4 is a special case of the Künneth isomorphism (SGA 4 XVII 5.4.3).

1.7

Choose a compactification $f_i = p_i j_i$, where j_i is an open immersion and p_i is a proper morphism. Composing the evident canonical isomorphism (where $j = j_1 \times_S j_2$)

$$j_{1!}L_1 \otimes_S^L j_{2!}L_2 \xrightarrow{\sim} j_!(L_1 \otimes_S^L L_2)$$

with the isomorphism 1.6.4 relative to $(p_i, j_{i!}L_i)$, one obtains a Künneth isomorphism (SGA 4 XVII 5.4.3)

$$f_{1!}L_1 \otimes_S^L f_{2!}L_2 \xrightarrow{\sim} f_!(L_1 \otimes_S^L L_2). \tag{1.7.1}$$

One checks easily (loc. cit.) that 1.7.1 does not depend on the compactifications chosen, and is compatible with the transitivity isomorphisms for composites $g_i f_i$ (cf. (loc. cit. 5.2.4)). Thanks to 1.7.1, one can define, for $u_i \in \mathrm{Hom}_{f_i}^{(3)}(L_i, M_i)$,

$$u_1 \otimes_S^L u_2 \in \mathrm{Hom}_f^{(3)}(L, M) \tag{1.7.2}$$

with L and M as in 1.6.2, and one has a transitivity formula analogous to 1.6.3.

For $L_i = f_i^! M_i$, and u_i given by the identity of L_i, 1.7.2 gives a *Künneth arrow*

$$f_1^! M_1 \otimes_S^L f_2^! M_2 \longrightarrow f^!(M_1 \otimes_S^L M_2). \tag{1.7.3}$$

Proposition 1.7.4

The arrow 1.7.3 is an isomorphism.

By the transitivity formula, it suffices to treat the case where $X_2 = Y_2$, $f_2 = 1$. By dévissage, one reduces to $M_2 = g_* j_! A_V$, where $j : V \to U$ is an open immersion and $g : U \to Y_2$ a finite morphism, and then, by (SGA 4 XVIII 3.1.12.3), to the case where $M_2 = A_{Y_2}$. By localization on X_2, one may suppose moreover that $f_1 = g_1 j_1$, where j_1 is a closed immersion and g_1 a smooth morphism purely of relative dimension n_1. By transitivity, it suffices to treat the cases

$$\text{a) } f_1 = g_1, \qquad \text{b) } f_1 = j_1.$$

In case a), the trace morphism supplies by adjunction (SGA 4 XVIII 3.2.5) an isomorphism

$$f_1^* M_1(n_1)[2n_1] \xrightarrow{\sim} f_1^! M_1;$$

this is compatible with the base change $Y_2 \to S$, because the trace morphism is so (SGA 4 XVIII 2.9), whence 1.7.4 in this case. In case b), if i_1 denotes the inclusion of the complementary open, one has an exact sequence

$$0 \longrightarrow j_{1*} R j_1^! M_1 \longrightarrow M_1 \longrightarrow R i_{1*} i_1^* M_1 \longrightarrow 0,$$

and the compatibility of Ri_{1*} with base change, a special case of 1.6.4, gives the conclusion.

Thanks to 1.7.3, one can define, for $u_i \in \mathrm{Hom}_f^{(4)}(L_i, M_i)$,

$$u_1 \otimes_S^L u_2 \in \mathrm{Hom}_f^{(4)}(L, M) \tag{1.7.5}$$

(L and M as in 1.6.2), with a transitivity formula analogous to 1.6.3.

On the other hand, with the notation of 1.3, 1.7.3 gives an isomorphism

$$K_{X_1} \otimes_S^L K_{X_2} \xrightarrow{\sim} K_X. \tag{1.7.6}$$

1.8

Let $f : X \to Y$ be an S-morphism, $L \in \operatorname{ob} D(X)$, $M \in \operatorname{ob} D(Y)$, S' an S-scheme, $P \in \operatorname{ob} D(S')$, and $f' : X' \to Y'$ the morphism deduced from f by the base change $S' \to S$. The identity arrow of P may be regarded indifferently as an arrow of type i $(1 \leq i \leq 4)$ over the identity arrow of S'; for $u \in \operatorname{Hom}_f^{(i)}(L, M)$ $(1 \leq i \leq 4)$, one may therefore, by 1.6.2, 1.7.2, 1.7.5, consider

$$u \otimes_S^L \operatorname{Id}_P \in \operatorname{Hom}_{f'}^{(i)}(L \otimes_S^L P, M \otimes_S^L P). \tag{1.8.1}$$

We shall sometimes write $u \otimes_S^L P$ instead of $u \otimes_S^L \operatorname{Id}_P$.

3 Functoriality of RHom and external tensor products

2.1

Let $f : X \to Y$ be an S-morphism, $P \in \operatorname{ob} D(Y)$, $Q \in \operatorname{ob} D^+(Y)$. The evident canonical arrow at the level of complexes

$$f^*\mathcal{H}om^\bullet(P, Q) \longrightarrow \mathcal{H}om^\bullet(f^*P, f^*Q)$$

gives by derivation a canonical arrow

$$f^*\mathrm{RHom}(P, Q) \longrightarrow \mathrm{RHom}(f^*P, f^*Q). \tag{2.1.1}$$

Let $L \in \operatorname{ob} D(X)$, $M \in \operatorname{ob} D^+(X)$. Put

$$\operatorname{Hom}_f^{(i,j)}((L, M), (P, Q)) = \operatorname{Hom}_f^{(i)}(L, P) \times \operatorname{Hom}_f^{(j)}(M, Q), \tag{2.1.2}$$

with the notation of 1.4. For $(u, v) \in \operatorname{Hom}_f^{(2,1)}((L, M), (P, Q))$ one defines

$$\mathrm{RHom}(u, v) \in \operatorname{Hom}_f^{(1)}(\mathrm{RHom}(L, M), \mathrm{RHom}(P, Q)) \tag{2.1.3}$$

by composing 2.1.1 with the arrow $\mathrm{RHom}(f^*P, f^*Q) \to \mathrm{RHom}(L, M)$ defined by u and v. For $L = f^*P$, $Q = f_*M$, u (resp. v) given by the identity of L (resp. Q), $\mathrm{RHom}(u, v)$ is the "trivial duality" isomorphism

$$\mathrm{RHom}(P, f_*M) \xrightarrow{\sim} f_*\mathrm{RHom}(f^*P, M). \tag{2.1.4}$$

For $(u, v) \in \operatorname{Hom}_f^{(3,4)}((L, M), (P, Q))$, one defines

$$\mathrm{RHom}(u, v) \in \operatorname{Hom}_f^{(1)}(\mathrm{RHom}(L, M), \mathrm{RHom}(P, Q)) \tag{2.1.5}$$

as the composite of the arrows

$$\mathrm{RHom}(P, Q) \xrightarrow{a} \mathrm{RHom}(f_!L, Q) \xrightarrow{b} f_*\mathrm{RHom}(L, f^!Q) \xrightarrow{c} f_*\mathrm{RHom}(L, M),$$

where a (resp. c) is defined by u (resp. v), and b is the inverse of the duality isomorphism (SGA 4 XVIII 3.1.9.6).

It follows easily from the definitions that the formation of $\mathrm{RHom}(u, v)$ is compatible with composition: for composable (u, v), (u', v') of type $(2, 1)$ (resp. $(3, 4)$), one has

$$\mathrm{RHom}(u'u, v'v) = \mathrm{RHom}(u', v')\,\mathrm{RHom}(u, v). \tag{2.1.6}$$

2.2

Let X be an S-scheme. Recall that for $L \in \operatorname{ob} D^-(X)$, $M \in \operatorname{ob} D(X)$, $N \in \operatorname{ob} D^+(X)$, one has the adjunction isomorphism ("dear to Cartan," as Grothendieck says)

$$\operatorname{Hom}(L \otimes^L M, N) = \operatorname{Hom}(L, \operatorname{RHom}(M, N)). \tag{2.2.1}$$

For $E \in \operatorname{ob} D^-(X)$, $F \in \operatorname{ob} D^+(X)$, the identity arrow of $\operatorname{RHom}(E, F)$ defines via 2.2.1 an arrow

$$E \otimes^L \operatorname{RHom}(E, F) \longrightarrow F, \tag{2.2.2}$$

called the *evaluation arrow*: it is derived from the arrow at the level of complexes

$$\mathcal{H}om^\bullet(E, F) \otimes E \longrightarrow F, \qquad f \otimes x \longmapsto f(x).$$

Let, for $i = 1, 2$, $E_i, F_i \in \operatorname{ob} D_{\mathrm{ctf}}(X)$. By adjunction (2.2.1), the arrow

$$E_1 \otimes^L E_2 \otimes^L \operatorname{RHom}(E_1, F_1) \otimes^L \operatorname{RHom}(E_2, F_2) \longrightarrow F_1 \otimes^L F_2,$$

composed of a symmetry isomorphism and of the tensor product of the evaluation arrows relative to (E_1, F_1) and (E_2, F_2), supplies an arrow

$$\operatorname{RHom}(E_1, F_1) \otimes^L \operatorname{RHom}(E_2, F_2) \longrightarrow \operatorname{RHom}(E_1 \otimes^L E_2, F_1 \otimes^L F_2). \tag{2.2.3}$$

Let, for $i = 1, 2$, X_i be an S-scheme, $X = X_1 \times_S X_2$, $p_i : X \to X_i$ the canonical projection, $E_i, F_i \in \operatorname{ob} D_{\mathrm{ctf}}(X_i)$, $E = E_1 \otimes_S^L E_2$, $F = F_1 \otimes_S^L F_2$. One has a canonical arrow

$$\operatorname{RHom}(E_1, F_1) \otimes_S^L \operatorname{RHom}(E_2, F_2) \longrightarrow \operatorname{RHom}(E, F), \tag{2.2.4}$$

obtained by composing the tensor product of the arrows $p_i^* \operatorname{RHom}(E_i, F_i) \to \operatorname{RHom}(p_i^* E_i, p_i^* F_i)$ and 2.2.3 for $(p_i^* E_i, p_i^* F_i)$.

Proposition 2.3

The arrow 2.2.4 is an isomorphism.

By localization and dévissage, one reduces to $E_i = f_{i!} A_{U_i}$ for $f_i : U_i \to X_i$ étale. One has canonical isomorphisms (duality)

$$\operatorname{RHom}(f_{i!} A_{U_i}, F_i) \xrightarrow{\sim} f_{i*} f_i^* F_i, \qquad \operatorname{RHom}(E, F) \xrightarrow{\sim} f_* f^* F \quad (f = f_1 \times_S f_2). \tag{1}$$

Taking into account the Künneth formula 1.6.4, it suffices, to conclude, to verify that these isomorphisms make the square

$$\begin{array}{ccc} \operatorname{RHom}(f_{1!} A_{U_1}, F_1) \otimes_S^L \operatorname{RHom}(f_{2!} A_{U_2}, F_2) & \xrightarrow{2.2.3} & \operatorname{RHom}(f_! A_U, F) \\ \downarrow \sim & & \downarrow \sim \\ f_{1*} f_1^* F_1 \otimes_S^L f_{2*} f_2^* F_2 & \xrightarrow[1.6.4]{} & f_* f^* F \end{array} \tag{2}$$

commute, where $U = U_1 \times_S U_2$. Since f_i is étale, the isomorphism (1) relative to f_i (resp. f) is adjoint to the composite arrow

$$f_i^* \operatorname{RHom}(f_{i!} A_{U_i}, F_i) \xrightarrow{\sim} \operatorname{RHom}(f_i^* f_{i!} A_{U_i}, f_i^* F_i) \longrightarrow f_i^* F_i, \tag{3}$$

where the second arrow is deduced from the adjunction $A_{U_i} \to f_i^* f_{i!} A_{U_i}$ (resp. the analogous composite arrow with f). The commutativity of (2) is equivalent to that of the square

$$\begin{array}{ccc} f_1^*\mathrm{RHom}(f_{1!}A_{U_1}, F_1) \otimes_S^L f_2^*\mathrm{RHom}(f_{2!}A_{U_2}, F_2) & \longrightarrow & f^*\mathrm{RHom}(f_!A_U, F) \\ \downarrow & & \downarrow \\ f_1^*F_1 \otimes_S^L f_2^*F_2 & \xrightarrow[\sim]{} & f^*F, \end{array} \tag{4}$$

where the vertical arrows are given by (3). But the commutativity of (4) follows from the fact that 2.2.3 is functorial in E_i and reduces to the identity for $E_i = A$, whence the proposition.

2.4

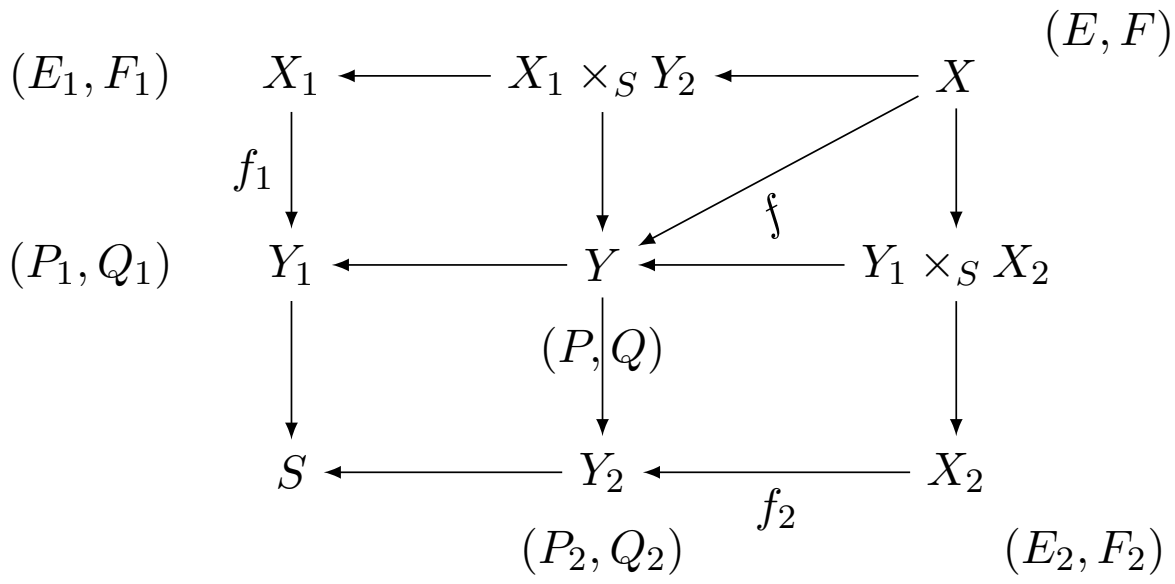
Let, for $i = 1, 2$, $f_i : X_i \to Y_i$ be an S-morphism,

$$f = f_1 \times_S f_2 : X \to Y,$$

$E_i, F_i \in \mathrm{ob}\, D_{\mathrm{ctf}}(X_i)$, $P_i, Q_i \in \mathrm{ob}\, D_{\mathrm{ctf}}(Y_i)$,

$$E = E_1 \otimes_S^L E_2, \quad F = F_1 \otimes_S^L F_2, \quad P = P_1 \otimes_S^L P_2, \quad Q = Q_1 \otimes_S^L Q_2.$$

Consider the diagram



(2.4.0)

Give ourselves $(u_1, v_1) \in \mathrm{Hom}_{f_1}^{(3,4)}((E_1, F_1), (P_1, Q_1))$, $(u_2, v_2) \in \mathrm{Hom}_{f_2}^{(2,1)}((E_2, F_2), (P_2, Q_2))$ (notation of 2.1.2 and 1.4). By 1.8, one deduces from (u_i, v_i) a square

$$\begin{array}{ccc} (E, F) & \xleftarrow{(E_1 \otimes_S^L u_2,\, F_1 \otimes_S^L v_2)} & (E_1 \otimes_S^L P_2, F_1 \otimes_S^L Q_2) \\ \downarrow{\scriptstyle (u_1 \otimes_S^L E_2,\, v_1 \otimes_S^L F_2)} & & \downarrow{\scriptstyle (u_1 \otimes_S^L P_2,\, v_1 \otimes_S^L Q_2)} \\ (P_1 \otimes_S^L E_2, Q_1 \otimes_S^L F_2) & \xrightarrow[(P_1 \otimes_S^L u_2,\, Q_1 \otimes_S^L v_2)]{} & (P, Q), \end{array} \tag{2.4.1}$$

where the vertical arrows (resp. horizontal arrows) are of type $(3,4)$ (resp. $(2,1)$).

We may now state the main compatibility of this number, which will play an essential role in the verification of the Lefschetz–Verdier formula.

Proposition 2.5

The diagram 2.5.1 below, where the square on the right is deduced from 2.4.1 by applying RHom in the sense of 2.1.3 and 2.1.5, is commutative:

$$\begin{array}{ccccc}
\mathrm{RHom}(E_1,F_1)\otimes_S^L \mathrm{RHom}(E_2,F_2) & & \xrightarrow{2.2.4} & & \mathrm{RHom}(E,F) \\
\downarrow & & & \swarrow \quad \searrow & \\
\mathrm{RHom}(u_1,v_1)\otimes_S^L \mathrm{RHom}(u_2,v_2) & & \mathrm{RHom}(E_1\otimes_S^L P_2, F_1\otimes_S^L Q_2) & & \mathrm{RHom}(P_1\otimes_S^L E_2, Q_1\otimes_S^L F_2) \\
\downarrow & & & \searrow \quad \swarrow & \\
\mathrm{RHom}(P_1,Q_1)\otimes_S^L \mathrm{RHom}(P_2,Q_2) & & \xrightarrow[2.2.4]{} & & \mathrm{RHom}(P,Q)
\end{array} \tag{2.5.1}$$

2.6

The proof of 2.5 will occupy the rest of no. 2. It follows from 1.6.3 that, if $w_i : L_i \to M_i$ is an arrow of type 1 over f_i, the arrow $w = w_1 \otimes_S^L w_2$ makes the diagram

$$\begin{array}{ccccc}
 & & L_1\otimes_S^L L_2 & & \\
 & \swarrow^{L_1\otimes_S^L w_2} & & \searrow^{w_1\otimes_S^L L_2} & \\
L_1\otimes_S^L M_2 & & & & M_1\otimes_S^L L_2 \\
 & \searrow_{w_1\otimes_S^L M_2} & & \swarrow_{M_1\otimes_S^L w_2} & \\
 & & M_1\otimes_S^L M_2 & &
\end{array}$$

commute. Applying this remark to $w_i = \mathrm{RHom}(u_i, v_i)$, one sees that it suffices to prove the following special cases of 2.5.

Corollary 2.6.1

Let $f : X \to Y$ be an S-morphism, S' an S-scheme, $f' : X' \to Y'$ the morphism deduced from f by the base change $S' \to S$, $E, F \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$, $P, Q \in \mathrm{ob}\, D_{\mathrm{ctf}}(Y)$, $P', Q' \in \mathrm{ob}\, D_{\mathrm{ctf}}(S')$, and $(u,v) \in \mathrm{Hom}_f^{(2,1)}((E,F),(P,Q))$ (resp. $\mathrm{Hom}_f^{(3,4)}((E,F),(P,Q))$). Then one has a commutative square, whose vertical arrows are of type 1 over f':

$$\begin{array}{ccc}
\mathrm{RHom}(E,F)\otimes_S^L \mathrm{RHom}(P',Q') & \xrightarrow{2.2.4} & \mathrm{RHom}(E\otimes_S^L P', F\otimes_S^L Q') \\
\downarrow{\scriptstyle \mathrm{RHom}(u,v)\otimes_S^L \mathrm{RHom}(P',Q')} & & \downarrow{\scriptstyle \mathrm{RHom}(u\otimes_S^L P', v\otimes_S^L Q')} \\
\mathrm{RHom}(P,Q)\otimes_S^L \mathrm{RHom}(P',Q') & \xrightarrow[2.2.4]{} & \mathrm{RHom}(P\otimes_S^L P', Q\otimes_S^L Q').
\end{array} \tag{2.6.1.1}$$

First examine the case where (u, v) is of type $(2, 1)$. By functoriality, one may suppose that $E = f^*P$, $F = f^*Q$, (u, v) being given by the identity of (f^*P, f^*Q). The commutativity of 2.6.1.1 in the case $P' = Q' = A_{S'}$ is evident; to establish it in the general case, it therefore suffices to verify that, for $L, M \in \mathrm{ob}\, D_{\mathrm{ctf}}(Y)$, the square

$$\begin{array}{ccc} f^*\mathrm{RHom}(E,F) \otimes^L f^*\mathrm{RHom}(L,M) & \xrightarrow{f^*(2.2.3)} & f^*\mathrm{RHom}(E \otimes^L L, F \otimes^L M) \\ \downarrow{\scriptstyle 2.1.1 \otimes 2.1.1} & & \downarrow{\scriptstyle 2.1.1} \\ \mathrm{RHom}(f^*E, f^*F) \otimes^L \mathrm{RHom}(f^*L, f^*M) & \xrightarrow[2.2.3]{} & \mathrm{RHom}(f^*(E \otimes^L L), f^*(F \otimes^L M)) \end{array}$$

is commutative. But one sees immediately that the two composites of this square are adjoint to the tensor product of the evaluation arrows

$$f^*E \otimes^L f^*\mathrm{RHom}(E,F) \longrightarrow f^*F \quad \text{and} \quad f^*L \otimes^L f^*\mathrm{RHom}(L,M) \longrightarrow f^*M,$$

which proves the assertion.

Now pass to the case where (u, v) is of type $(3, 4)$. By functoriality, one may suppose that $P = f_!E$, $F = f^!Q$, (u, v) being defined by $(\mathrm{Id}_P, \mathrm{Id}_F)$. One must prove the commutativity of the square

$$\begin{array}{ccc} f_*\mathrm{RHom}(E, f^!Q) \otimes^L_S \mathrm{RHom}(P', Q') & \xrightarrow{b} & f'_*\mathrm{RHom}(E \otimes^L_S P', f^!Q \otimes^L_S Q') \\ \downarrow{\scriptstyle a \otimes^L_S \mathrm{RHom}(P',Q')} & & \downarrow{\scriptstyle a'} \\ \mathrm{RHom}(f_!E, Q) \otimes^L_S \mathrm{RHom}(P', Q') & \xrightarrow[2.2.4]{} & \mathrm{RHom}(f_!E \otimes^L_S P', Q \otimes^L_S Q'), \end{array}$$

where b is the composite of $f'_*(2.2.4)$ and a base-change isomorphism, a is the duality isomorphism (SGA 4 XVIII 3.1.9.6), and a' is the composite of the duality isomorphism (relative to $E \otimes^L_S P'$ and $Q \otimes^L_S Q'$) and the base-change isomorphisms

$$f_!E \otimes^L_S P' \xrightarrow[\sim]{c} f'_!(E \otimes^L_S P'), \qquad f^!Q \otimes^L_S Q' \xrightarrow[\sim]{d} f'^!(Q \otimes^L_S Q').$$

Recall that a is the composite of the canonical arrow (SGA 4 XVIII 3.1.9.5)

$$f_*\mathrm{RHom}(E, f^!Q) \longrightarrow \mathrm{RHom}(f_!E, f_!f^!Q)$$

and of the arrow defined by the adjunction arrow $f_!f^!Q \to Q$. There is an analogous description of a', as the composite of the quoted arrow

$$f'_*\mathrm{RHom}(E \otimes^L_S P', f^!Q \otimes^L_S Q') \longrightarrow \mathrm{RHom}(f'_!(E \otimes^L_S P'), f'_!(f^!Q \otimes^L_S Q')), \qquad (*)$$

of the arrows defined by c and d, and of the arrow defined by the adjunction arrow

$$f'_!f'^!(Q \otimes^L_S Q') \longrightarrow Q \otimes^L_S Q'.$$

By definition, d is adjoint to the arrow

$$f'_!(f^!Q \otimes^L_S Q') \longrightarrow Q \otimes^L_S Q'$$

defined by the base-change isomorphism $f'_!(f^!Q \otimes^L_S Q') \simeq f_! f^! Q \otimes^L_S Q'$ and the adjunction arrow $f_! f^! Q \to Q$; in other words, the square

$$\begin{array}{ccc} f'_!(f^!Q \otimes^L_S Q') & \xrightarrow{f'_! d} & f'_! f'^!(Q \otimes^L_S Q') \\ {\scriptstyle \text{base ch.}\ \sim}\downarrow & & \downarrow{\scriptstyle \text{adj}} \\ f_! f^! Q \otimes^L_S Q' & \xrightarrow[\text{adj}\otimes 1]{} & Q \otimes^L_S Q' \end{array}$$

is commutative. It follows that one may also describe a' as the composite of (*), of the arrow defined by c, and of those defined by the base-change isomorphism

$$f'_!(f^!Q \otimes^L_S Q') \xrightarrow{\sim} f_! f^! Q \otimes^L_S Q'$$

and the adjunction arrow $f_! f^! Q \to Q$. This decomposition of a' and that of a given above, together with the commutativity of the square

$$\begin{array}{ccc} \mathrm{RHom}(f_!E, f_! f^! Q) \otimes^L_S \mathrm{RHom}(P', Q') & \longrightarrow & \mathrm{RHom}(f_!E \otimes^L_S P', f_! f^! Q \otimes^L_S Q') \\ \downarrow & & \downarrow \\ \mathrm{RHom}(f_!E, Q) \otimes^L_S \mathrm{RHom}(P', Q') & \longrightarrow & \mathrm{RHom}(f_!E \otimes^L_S P', Q \otimes^L_S Q'), \end{array}$$

defined by 2.2.4 and the adjunction arrow $f_! f^! Q \to Q$, show that, to establish the commutativity of 2.6.2, it suffices to prove the following compatibility.

Lemma 2.6.3

Let f, f', E, F, P', Q' be as in 2.6.1. Then one has a commutative square

$$\begin{array}{ccc} f_*\mathrm{RHom}(E, F) \otimes^L_S \mathrm{RHom}(P', Q') & \xrightarrow{(1)} & f'_*\mathrm{RHom}(E \otimes^L_S P', F \otimes^L_S Q') \\ {\scriptstyle (2)}\downarrow & & \downarrow{\scriptstyle (4)} \\ \mathrm{RHom}(f_!E, f_!F) \otimes^L_S \mathrm{RHom}(P', Q') & \xrightarrow[(3)]{} & \mathrm{RHom}(f_!E \otimes^L_S P', f_!F \otimes^L_S Q'), \end{array}$$

where (1) is the composite of the base-change isomorphism

$$f_*\mathrm{RHom}(E, F) \otimes^L_S - \xrightarrow{\sim} f'_*(\mathrm{RHom}(E, F) \otimes^L_S -)$$

and f'_*(2.2.4), (2) is deduced from the canonical arrow

$$f_*\mathrm{RHom}(E, F) \longrightarrow \mathrm{RHom}(f_!E, f_!F)$$

(SGA 4 XVIII 3.1.9.5) by applying $\otimes^L_S \mathrm{RHom}(P', Q')$, (3) is given by 2.2.4, and finally (4) is the composite of the canonical arrow

$$f'_*\mathrm{RHom}(E \otimes^L_S P', F \otimes^L_S Q') \longrightarrow \mathrm{RHom}(f'_!(E \otimes^L_S P'), f'_!(F \otimes^L_S Q'))$$

(loc. cit.) and the arrows defined by the base-change isomorphisms

$$f'_!(E \otimes_S^L P') \xrightarrow{\sim} f_!E \otimes_S^L P', \qquad f'_!(F \otimes_S^L Q') \xrightarrow{\sim} f_!F \otimes_S^L Q'.$$

Returning to the definition of the arrow (SGA 4 XVIII 3.1.9.5), choose a compactification of f[11]; one is then reduced to proving the lemma separately in the case where f is an open immersion and in the case where f is a proper morphism.

a) Case where f is an open immersion. By adjunction (2.2.1), it suffices to see that, if one tensors the square 2.6.3 by $f_!E \otimes_S^L P'$ and composes with the evaluation arrow 2.2.2

$$(f_!E \otimes_S^L P') \otimes^L \mathrm{RHom}(f_!E \otimes_S^L P', f_!F \otimes_S^L Q') \longrightarrow f_!F \otimes_S^L Q',$$

the square obtained is commutative. But the sums of this square are zero outside X', so that it suffices to verify that the square induced on X' commutes, which is trivial.

b) Case where f is a proper morphism. Then $f_! = f_*$, $f'_! = f'_*$. One sees easily that the composite of

$$f_*\mathrm{RHom}(E, F) \longrightarrow \mathrm{RHom}(f_*E, f_*F)$$

with the trivial-duality isomorphism

$$\mathrm{RHom}(f_*E, f_*F) \xrightarrow{\sim} f_*\mathrm{RHom}(f^*f_*E, F)$$

(2.1.4) is none other than the arrow deduced from the adjunction arrow $f^*f_*E \to E$ by applying $f_*\mathrm{RHom}(-, F)$. Similarly, the composite of (4) with the trivial-duality isomorphism

$$\mathrm{RHom}(f_*E \otimes_S^L P', f_*F \otimes_S^L Q') \xrightarrow{\sim} f'_*\mathrm{RHom}(f^*f_*E \otimes_S^L P', F \otimes_S^L Q')$$

($f_*F \otimes_S^L Q'$ being identified with $f'_*(F \otimes_S^L Q')$ by the canonical isomorphism) is none other than the arrow deduced from the adjunction arrow $f^*f_*E \to E$ by applying $f'_*\mathrm{RHom}(- \otimes_S^L P', F \otimes_S^L Q')$. Thus one is reduced to verifying the commutativity of the square

$$\begin{array}{ccc} \mathrm{RHom}(f_*E, f_*F) \otimes_S^L \mathrm{RHom}(P', Q') & \xrightarrow{(3)} & \mathrm{RHom}(f_*E \otimes_S^L P', f_*F \otimes_S^L Q') \\ \downarrow & & \downarrow \\ f_*\mathrm{RHom}(f^*f_*E, F) \otimes_S^L \mathrm{RHom}(P', Q') & \xrightarrow[(1')]{} & f'_*\mathrm{RHom}(f^*f_*E \otimes_S^L P', F \otimes_S^L Q'), \end{array}$$

where the vertical arrows are the trivial-duality isomorphisms and $(1')$ is (1) with E replaced by f^*f_*E. But this is a special case of 2.6.1.1 in the case, already treated, where (u, v) is of type $(2, 1)$ (take $u : f^*f_*E \to f_*E$ given by the identity of f^*f_*E, and $v : F \to f_*F$ given by the identity of f_*F). We have therefore proved 2.6.3. As we have seen, the commutativity of 2.6.2 follows, which completes the proof of 2.6.1 and, finally, of 2.5.

[11] The arrow quoted is defined with the aid of such a compactification, but it does not depend on it: this point, tacitly admitted in (loc. cit.), is easily verified.

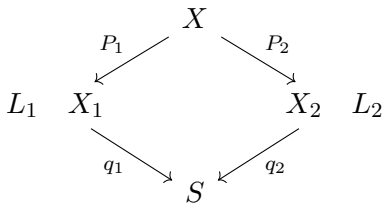
4 Cohomological Correspondences

3.1

Let, for $i = 1, 2$, X_i be an S-scheme and $L_i \in \mathrm{ob}\, D_{\mathrm{ctf}}(X_i)$, and let

$$X = X_1 \times_S X_2, \qquad p_i : X \longrightarrow X_i, \qquad q_i : X_i \longrightarrow S$$

be the canonical projections:



With the notation of 1.3, one has a canonical isomorphism (2.2.4)

$$DL_1 \overset{\mathbf{L}}{\otimes}_S L_2 \xrightarrow{\sim} \mathrm{RHom}(L_1 \overset{\mathbf{L}}{\otimes}_S A_{X_2}, q_1^! A_S \overset{\mathbf{L}}{\otimes}_S L_2).$$

Composing with the Künneth isomorphism

$$q_1^! A_S \overset{\mathbf{L}}{\otimes}_S L_2 \xrightarrow{\sim} p_2^! L_2 \qquad (1.7.3),$$

one obtains an isomorphism

$$DL_1 \overset{\mathbf{L}}{\otimes}_S L_2 \xrightarrow{\sim} \mathrm{RHom}(p_1^* L_1, p_2^! L_2). \tag{3.1.1}$$

This isomorphism will play a fundamental role throughout. For $X_i = S$, 3.1.1 reduces to

$$L_1^\vee \overset{\mathbf{L}}{\otimes} L_2 \xrightarrow{\sim} \mathrm{RHom}(L_1, L_2),$$

a special case of an isomorphism valid for perfect complexes on an arbitrary ringed topos (SGA 6 I 7.7). We set

$$\mathrm{RHom}(p_1^* L_1, p_2^! L_2) = \mathrm{RHom}_S(L_1, L_2), \qquad \mathrm{Hom}(p_1^* L_1, p_2^! L_2) = \mathrm{Hom}_S(L_1, L_2). \tag{3.1.2}$$

The elements of $\mathrm{Hom}_S(L_1, L_2)$ will be called *cohomological correspondences from L_1 to L_2*. Instead of "cohomological correspondence from A_{X_1} to A_{X_2}", we shall simply say *cohomological correspondence from X_1 to X_2* (understood: with coefficients in A).

If X_1 is *smooth*, purely of relative dimension r_1, then the same is true of p_2, and by the duality theorem (SGA 4 XVIII 3.2.5) one has

$$p_2^! L_2 \xrightarrow{\sim} p_2^* L_2(r_1)[2r_1],$$

therefore

$$\mathrm{RHom}_S(L_1, L_2) = \mathrm{RHom}(p_1^* L_1, p_2^* L_2)(r_1)[2r_1], \qquad \mathrm{Hom}_S(L_1, L_2) = \mathrm{H}^{2r_1}(X, \mathrm{RHom}(p_1^* L_1, p_2^* L_2)(r_1)). \tag{3.1.3}$$

In particular, the group of cohomological correspondences from X_1 to X_2 is identified in this case with $\mathrm{H}^{2r_1}(X, A(r_1))$.

3.2

The cohomological correspondences met in practice are associated with S-morphisms $X_2 \to X_1$, or more generally with cycles on X, or with schemes over X. Let

$$c : C \longrightarrow X$$

be a scheme over X (one sometimes says that c is a correspondence between X_1 and X_2), and put $c_i = p_i c : C \to X_i$ for the projections. We shall call *cohomological correspondences from L_1 to L_2 with support in c* (or in C, if there is no risk of confusion) the elements of the group

$$\mathrm{H}^0(X, c_!\mathrm{RHom}(c_1^*L_1, c_2^!L_2)) \quad (= \mathrm{Hom}(c_1^*L_1, c_2^!L_2) \text{ if } c \text{ is proper}).$$

By the induction formula (SGA 4 XVIII 3.1.12.2), one has a canonical isomorphism

$$c^!\mathrm{RHom}(p_1^*L_1, p_2^!L_2) \xrightarrow{\sim} \mathrm{RHom}(c_1^*L_1, c_2^!L_2), \tag{3.2.1}$$

whence, applying $c_!$ and composing with the adjunction arrow $c_!c^! \to \mathrm{Id}$, canonical arrows

$$c_!\mathrm{RHom}(c_1^*L_1, c_2^!L_2) \longrightarrow \mathrm{RHom}(p_1^*L_1, p_2^!L_2), \tag{3.2.2}$$

$$\mathrm{H}^0(X, c_!\mathrm{RHom}(c_1^*L_1, c_2^!L_2)) \longrightarrow \mathrm{Hom}_S(L_1, L_2). \tag{3.2.3}$$

Thus every correspondence from L_1 to L_2 with support in C canonically defines, by 3.2.3, a correspondence (without support) from L_1 to L_2.

Examples. a) Suppose that c is proper and that c_2 has finite tor-dimension and relative dimension $\leq N$. The trace morphism (SGA $4^{1/2}$ Cycle 2.3.3)

$$\mathrm{Tr}_{c_2} : c_{2!}A_C \longrightarrow A_{X_2}(-N)[-2N]$$

defines by adjunction a cohomological correspondence from A_{X_1} to $A_{X_2}(-N)[2N]$ with support in C, which will be called the *class of* (c, N), and will be denoted

$$\mathrm{cl}(c, N) \in \mathrm{H}^{-2N}(C, c_2^!A_{X_2}(-N)). \tag{3.2.4}$$

The most important case is that in which $N = 0$, i.e. c_2 is finite (and of finite tor-dimension); in that case $\mathrm{cl}(c)$ is a cohomological correspondence from X_1 to X_2 with support in C. If X_1 is smooth, purely of relative dimension r_1, then, by 3.1.3 and 3.2.1,

$$\mathrm{H}^{-2N}(C, c_2^!A_{X_2}(-N)) = \mathrm{H}^{2(r_1-N)}(C, c^!A_X(r_1 - N)). \tag{3.2.5}$$

If moreover c is a closed immersion, the second member rewrites as

$$\mathrm{H}_C^{2(r_1-N)}(X, A_X(r_1 - N)),$$

and the class of (c, N), considered as an element of this group, is precisely the cohomology class associated with c in the sense of (SGA $4^{1/2}$ Cycle 2.3.1), as follows immediately from the definitions.

b) Let $F : X_2 \to X_1$ be an S-morphism, and denote by $c(F) : C(F) \to X$ its graph, i.e. the image of the section of p_2 defined by F ("the set of points (Fx, x)"): c_2 is an isomorphism and $c_1c_2^{-1} = F$. One therefore has canonical isomorphisms

$$\mathrm{RHom}(c_1(F)^*L_1, c_2(F)^!L_2) = \mathrm{RHom}(F^*L_1, L_2), \qquad \mathrm{Hom}(c_1(F)^*L_1, c_2(F)^!L_2) = \mathrm{Hom}(F^*L_1, L_2). \tag{3.2.6}$$

In other words, the cohomological correspondences from L_1 to L_2 with support in the graph of F are the "lifts" of F to a homomorphism $F^*L_1 \to L_2$. Here are two important examples of such correspondences:

(i) $X_1 = X_2$, $L_1 = L_2$, $F = 1$ is the identity of X_1, whose graph Δ is the diagonal. The correspondence with support in Δ defined by the identity of L_1 is called the *diagonal correspondence*. It is the element

$$1 \in \mathrm{Hom}(L_1, L_1) = \mathrm{H}^0(X, \Delta_*\Delta^!\mathrm{RHom}_S(L_1, L_1))$$

(a group that is identified with $\mathrm{H}^{2r}_\Delta(X, \mathrm{RHom}_S(L_1, L_1)(r))$ when X_1 is smooth, purely of relative dimension r).

(ii) Suppose that S is the spectrum of a finite field $\mathbb{F}_q$, that $X_1 = X_2$, $L_1 = L_2$, and take for $F : X_1 \to X_1$ the relative Frobenius endomorphism over $\mathbb{F}_q$, the identity on the underlying space and raising to the q-th power on $\mathcal{O}_{X_1}$ (cf. XIV), and take as lift of F to L_1 the canonical isomorphism

$$F^*L_1 \xrightarrow{\sim} L_1$$

(loc. cit. §2, Prop. 1) (more precisely, the a-th iterate of the isomorphism of (loc. cit.) if $q = p^a$). The cohomological correspondence from L_1 to L_1 with support in the graph of F so defined is called the *Frobenius correspondence* (relative to $\mathbb{F}_q$).

c) Certain cohomological correspondences between sheaves on curves, related to Hecke operators, have been studied by Langlands in ([13] §7).

d) Cohomological correspondences between constant sheaves (the most frequent ones in nature) furnish in a natural way, by "integration", cohomological correspondences between complexes, as we shall now see.

3.3

Let, for $i = 1, 2$, $f_i : X_i \to Y_i$ be an S-morphism, and put

$$f = f_1 \times_S f_2 : X \to Y, \qquad f_1' = f_1 \times_S Y_2, \qquad f_2' = Y_1 \times_S f_2,$$
$$p_1' = X_1 \times_S f_2, \qquad p_2' = f_1 \times_S X_2.$$

$$\begin{array}{ccc} X_1 \times_S Y_2 & \xleftarrow{p_1'} & X \\ {\scriptstyle f_1'}\downarrow & \swarrow_{f} & \downarrow{\scriptstyle p_2'} \\ Y & \xleftarrow[f_2']{} & Y_1 \times_S X_2 \end{array} \tag{3.3.0}$$

Let $L_i \in \mathrm{ob}\, D_{\mathrm{ctf}}(X_i)$. There exists a unique isomorphism

$$f_*\mathrm{RHom}_S(L_1, L_2) \xrightarrow{\sim} \mathrm{RHom}_S(f_{1!}L_1, f_{2*}L_2) \tag{3.3.1}$$

whose inverse makes the square

$$\begin{array}{ccc} D(f_{1!}L_1) \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2 & \xrightarrow{3.1.1} & \mathrm{RHom}_S(f_{1!}L_1, f_{2*}L_2) \\ {\scriptstyle (1)}\downarrow & & \downarrow \\ f_{1*}DL_1 \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2 & \xrightarrow[(2)]{} & f_*\mathrm{RHom}_S(L_1, L_2), \end{array}$$

commutative, where (1) is deduced from the inverse of the duality isomorphism (SGA 4 XVIII 3.1.9.6)

$$Df_{1!}L_1 \xrightarrow{\sim} f_{1*}DL_1$$

by applying $- \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2$, and (2) is the composite of the Künneth isomorphism

$$f_{1*}DL_1 \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2 \xrightarrow{\sim} f_*(DL_1 \overset{\mathbf{L}}{\otimes}_S L_2)$$

and $f_*(3.1.1)$. Applying $R\Gamma(Y, -)$ to 3.3.1, one obtains an isomorphism

$$f_* : \mathrm{Hom}_S(L_1, L_2) \xrightarrow{\sim} \mathrm{Hom}_S(f_{1!}L_1, f_{2*}L_2). \tag{3.3.2}$$

For $u \in \mathrm{Hom}_S(L_1, L_2)$, the correspondence f_*u will be called the *direct image* of u by f. When $Y_1 = Y_2 = S$, we shall write u_* rather than f_*u. If $Y_1 = Y_2 = S$ is the spectrum of a separably closed field, 3.3.2 reads

$$\mathrm{Hom}_S(L_1, L_2) \xrightarrow{\sim} \mathrm{Hom}(R\Gamma_c(X_1, L_1), R\Gamma(X_2, L_2)). \tag{3.3.3}$$

Thus cohomological correspondences "operate" on cohomology. The following statement will allow us to interpret this operation in several ways, and in particular to relate it to the usual definitions in situations such as a) or b) above.

Proposition 3.4. With the notation of 3.3.0, one has a commutative diagram of isomorphisms in $D_{\mathrm{ctf}}(Y)$:

$$\begin{array}{ccccc} & & \mathrm{RHom}_S(f_{1!}L_1, f_{2*}L_2) & & \\ & \overset{(1)}{\swarrow} & \downarrow (5) & \overset{(2)}{\searrow} & \\ f'_{1*}\mathrm{RHom}_S(L_1, f_{2*}L_2) & & & & f'_{2*}\mathrm{RHom}_S(f_{1!}L_1, L_2) \\ & {\scriptstyle f'_{1*}(3)}\searrow & \downarrow & \swarrow{\scriptstyle f'_{2*}(4)} & \\ & & f_*\mathrm{RHom}_S(L_1, L_2) & & \end{array} \tag{3.4.1}$$

where (5) is the inverse of 3.3.1 and the arrows (1) to (4) are defined by the commutative diagrams below; in these diagrams "base ch." denotes an arrow deduced from a base-change or Künneth isomorphism of one of the types considered in no. 1, "dual." an arrow deduced from a duality isomorphism of type 2.1.4 or (SGA 4 XVIII 3.1.9.6), and "triv." a trivial isomorphism:

$$\begin{array}{ccc} \mathrm{RHom}(f_{1!}L_1 \overset{\mathbf{L}}{\otimes}_S A_{Y_2}, K_{Y_1} \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2) & \xrightarrow{\text{base ch.}} & \mathrm{RHom}_S(f_{1!}L_1, f_{2*}L_2) \\ \downarrow{\scriptstyle \text{base ch.}} & & \\ \mathrm{RHom}(f'_{1!}(L_1 \overset{\mathbf{L}}{\otimes}_S A_{Y_2}), K_{Y_1} \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2) & & \downarrow{\scriptstyle (1)} \\ \downarrow{\scriptstyle \text{dual.}} & & \\ f'_{1*}\mathrm{RHom}(L_1 \overset{\mathbf{L}}{\otimes}_S A_{Y_2}, f_1^{\prime !}(K_{Y_1} \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2)) & & \\ \downarrow{\scriptstyle \text{base ch.}} & & \\ f'_{1*}\mathrm{RHom}(L_1 \overset{\mathbf{L}}{\otimes}_S A_{Y_2}, K_{X_1} \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2) & \xrightarrow[\text{base ch.}]{} & f'_{1*}\mathrm{RHom}_S(L_1, f_{2*}L_2), \end{array}$$

$$
\begin{array}{ccc}
\mathrm{RHom}(f_{1!}L_1 \overset{\mathbf{L}}{\otimes}_S A_{Y_2}, K_{Y_1} \overset{\mathbf{L}}{\otimes}_S f_{2*}L_2) & \xrightarrow{\text{base ch.}} & \mathrm{RHom}_S(f_{1!}L_1, f_{2*}L_2) \\
\downarrow{\scriptstyle \text{base ch.}} & & \\
\mathrm{RHom}(f_{1!}L_1 \overset{\mathbf{L}}{\otimes}_S A_{Y_2}, f'_{2*}(K_{Y_1} \overset{\mathbf{L}}{\otimes}_S L_2)) & & \\
\downarrow{\scriptstyle \text{dual.}} & & \\

\qquad (4)
$$

This is only an explication of 2.5 in the particular case where $(u_1, v_1) : (L_1, K_{X_1}) \to (f_{1!}L_1, K_{Y_1})$ is given by the identity of $f_{1!}L_1$ and the canonical isomorphism $f_1^! K_{Y_1} \xrightarrow{\sim} K_{X_1}$, and where $(u_2, v_2) : (A_{X_2}, L_2) \to (A_{Y_2}, f_{2*}L_2)$ is given by the canonical isomorphism $A_{X_2} \xrightarrow{\sim} f_2^! A_{Y_2}$ and the identity of $f_{2*}L_2$.

Corollary 3.5. Assume that $Y_1 = Y_2 = S$. Let $u \in \mathrm{Hom}_S(L_1, L_2)$. The direct image $f_*u \in \mathrm{Hom}(f_{1!}L_1, f_{2*}L_2)$ (3.3.2) can be obtained in the following two equivalent ways:

a) Identify u, by trivial duality, with an arrow

$$L_1 \longrightarrow p_{1*}p_2^! L_2;$$

compose with the base-change isomorphism

$$p_{1*}p_2^!L_2 \xrightarrow{\sim} f_1^! f_{2*}L_2;$$

f_*u is the adjoint of this composite arrow.

b) Identify u, by adjunction, with an arrow

$$p_{2!}p_1^*L_1 \longrightarrow L_2;$$

compose with the base-change isomorphism

$$f_2^* f_{1!}L_1 \xrightarrow{\sim} p_{2!}p_1^*L_1;$$

f_*u is the adjoint of this composite arrow.

Description a) (respectively b)) indeed corresponds to the path $(f_{1*}(3) \circ (1))^{-1}$ (respectively $f_{2*}(4) \circ (2)$) in 3.4.1.

3.6

In practice, it is mainly description 3.5 b) that is used. Let us spell it out at the level of cohomology classes, assuming, in order to lighten the notation, that S is the spectrum of a separably closed field. Let

$$u \in \mathrm{Hom}_S(L_1, L_2) = \mathrm{Hom}(p_1^*L_1, p_2^!L_2).$$

For $x \in \mathrm{H}_c^i(X_1, L_1)$, $u_*(x) \in \mathrm{H}^i(X_2, L_2)$ is defined as follows: consider the element $p_1^*x \in \mathrm{H}^i(X_2, p_{2!}p_1^*L_1)$ deduced from x by inverse image, apply u to it, i.e. form the product

$$u \cdot p_1^*x \in \mathrm{H}^i(X_2, p_{2!}p_2^!L_2),$$

then apply the arrow

$$a : \mathrm{H}^i(X_2, p_{2!}p_2^!L_2) \longrightarrow \mathrm{H}^i(X_2, L_2)$$

defined by the adjunction arrow $p_{2!}p_2^! \to \mathrm{Id}$; in short:

$$u_*(x) = a(u \cdot p_1^*x). \tag{3.6.1}$$

Let $c : C \to X$ be a proper morphism, and let $u \in \mathrm{Hom}(c_1^*L_1, c_2^!L_2)$. Denote by

$$u_* \in \mathrm{Hom}\big(R\Gamma_c(X_1, L_1), R\Gamma(X_2, L_2)\big)$$

the image of u under the composite of 3.2.3 and 3.3.3. It follows from 3.6.1 that, for $x \in \mathrm{H}_c^i(X_1, L_1)$, one has

$$u_*(x) = a(u \cdot c_1^*x), \tag{3.6.2}$$

where c_1^*x is the inverse image of x in $\mathrm{H}^i(X_2, c_{2!}c_1^*L_1)$ and

$$a : \mathrm{H}^i(X_2, c_{2!}c_2^!L_2) \longrightarrow \mathrm{H}^i(X_2, L_2)$$

is the arrow deduced from the adjunction $c_{2!}c_2^!L_2 \to \mathrm{Id}$. In the situation of Example 3.2 a), one thus finds

$$\mathrm{cl}(c, N)_*(x) = \mathrm{Tr}_{c_2}(c_1^*x), \tag{3.6.3}$$

where

$$\mathrm{Tr}_{c_2} : \mathrm{H}^i(X_2, Rc_{2!}A_C) \longrightarrow \mathrm{H}^{i-2N}(X_2, A(-N))$$

is the arrow induced by the trace morphism relative to c_2. For $N = 0$, this formula agrees with (SGA $4^{1/2}$ Cycle 3.6): $\mathrm{cl}(c)_*$ is the homomorphism denoted η_{X_2,X_1} there. If X_1 is smooth, purely of relative dimension r_1, and c is a closed immersion, it follows from 3.6.1 and from the remark made at the end of 3.2 a) that one also has

$$\mathrm{cl}(c, N)_*(x) = \mathrm{Tr}_{p_2}(\mathrm{cl}(c)\, p_1^* x), \tag{3.6.4}$$

where $\mathrm{cl}(C) \in \mathrm{H}_C^{2(r_1-N)}(X, A(r_1 - N))$ is the cohomology class of C and

$$\mathrm{Tr}_{p_2} : \mathrm{H}^*(X_2, Rp_{2!}A_X) \longrightarrow \mathrm{H}^{*-2r_1}(X_2, A(-r_1))$$

is the arrow defined by the trace morphism relative to p_2. This recovers the usual definition of the homomorphism induced on cohomology by a correspondence ([12] 1.3), (SGA $4^{1/2}$ Cycle 3.2).

3.6.5

In the situation of 3.2 b), it follows from 3.6.2 that, for $u \in \mathrm{Hom}(F^*L_1, L_2)$,

$$u_* : \mathrm{H}_c^i(X_1, L_1) \longrightarrow \mathrm{H}^i(X_2, L_2)$$

is the composite of the "inverse image" homomorphism

$$\mathrm{H}_c^i(X_1, L_1) \longrightarrow \mathrm{H}^i(X_2, F^*L_1)$$

and the homomorphism induced by u (more generally, $f_*u : Rf_{1!}L_1 \to Rf_{2*}L_2$ is the composite of the canonical homomorphism

$$Rf_{1!}L_1 \longrightarrow Rf_{2*}F^*L_1$$

and of $Rf_{2*}u$). In particular, the diagonal correspondence induces the canonical arrow

$$Rf_{1!}L_1 \longrightarrow Rf_{1*}L_1$$

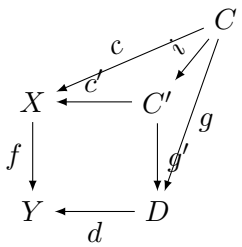
(the identity if X_1 is proper over S).

3.7

Return to the situation of the beginning of 3.3, assuming in addition that a commutative square

$$\begin{array}{ccc} X & \xleftarrow{c} & C \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle g} \\ Y & \xleftarrow[d]{} & D \end{array} \tag{3.7.1}$$

is given, with c proper. Put $c_i = p_i c$, $d_i = q_i d$, where $p_i : X \to X_i$, $q_i : Y \to Y_i$ are the projections. From 3.7.1 one deduces a commutative diagram whose inner square is cartesian:



(3.7.2)

For $K \in \operatorname{ob} D_{\mathrm{ctf}}(X)$, there is a canonical arrow

$$f_* c_! c^! K \longrightarrow d_* d^! f_* K, \tag{3.7.3}$$

which is the composite of the arrow

$$f_* c_! c^! K = f_* c'_* (i_* i^!) c'^! K \longrightarrow f_* c'_* c'^! K = d_* g'_* c'^! K$$

defined by the adjunction arrow $i_* i^! \to \mathrm{Id}$, and the isomorphism

$$d_* g'_* c'^! K \xrightarrow{\sim} d_* d^! f_* K$$

defined by the canonical isomorphism $g'_* d'^! \xrightarrow{\sim} d^! f_*$ (SGA 4 XVIII 3.1.12.3). Taking $K = \mathrm{RHom}_S(L_1, L_2)$, and composing 3.7.3 with the isomorphism deduced from 3.3.1, one obtains a canonical arrow

$$f_* c_* c^! \mathrm{RHom}_S(L_1, L_2) \longrightarrow d_* d^! \mathrm{RHom}_S(f_{1!} L_1, f_{2*} L_2), \tag{3.7.4}$$

which, by 3.2.1, may be rewritten as

$$f_* c_! \mathrm{RHom}(c_1^* L_1, c_2^! L_2) \longrightarrow d_* \mathrm{RHom}(d_1^* (f_{1!} L_1), d_2^! (f_{2*} L_2)). \tag{3.7.5}$$

One deduces

$$f_* : \mathrm{Hom}(c_1^* L_1, c_2^! L_2) \longrightarrow \mathrm{Hom}(d_1^* (f_{1!} L_1), d_2^! (f_{2*} L_2)). \tag{3.7.6}$$

The arrow 3.7.5 (respectively 3.7.6) generalizes 3.3.1 (respectively 3.3.2), with which it coincides when c and d are the identity. Also note that, for c proper, 3.2.2 (respectively 3.2.3) is nothing other than 3.7.5 (respectively 3.7.6) when f_1, f_2, and d are the identity arrows. When $Y_1 = Y_2 = S = D$, we shall abbreviate $f_* u$ as u_*, as above.

5 Pairings of Correspondences. Lefschetz Formula

4.1

Let, for $i = 1, 2$, X_i be an S-scheme, $X = X_1 \times_S X_2$, $p_i : X \to X_i$ the projections, $L_i \in \operatorname{ob} D_{\mathrm{ctf}}(X_i)$, and K_{X_i} the dualizing complex (1.3). The canonical arrows

$$p_i^* \mathrm{RHom}(L_i, K_{X_i}) \overset{\mathbf{L}}{\otimes} p_i^* L_i \longrightarrow p_i^* K_{X_i}, \tag{4.1.1}$$

composed from 2.1.1 and the evaluation arrow 2.2.2, give, by tensor product on X and composition with the Künneth isomorphism 1.7.6, a pairing

$$(DL_1 \overset{\mathbf{L}}{\otimes}_S L_2) \overset{\mathbf{L}}{\otimes} (L_1 \overset{\mathbf{L}}{\otimes}_S DL_2) \longrightarrow K_X, \tag{4.1.2}$$

which may be rewritten, by 3.1.1 and 3.1.2, as

$$\mathrm{RHom}_S(L_1, L_2) \overset{\mathbf{L}}{\otimes} \mathrm{RHom}_S(L_2, L_1) \longrightarrow K_X. \tag{4.1.3}$$

One deduces a pairing, called cup product,

$$\langle\ ,\ \rangle : \mathrm{Hom}_S(L_1, L_2) \otimes \mathrm{Hom}_S(L_2, L_1) \longrightarrow \mathrm{H}^0(X, K_X). \tag{4.1.4}$$

One may also regard 4.1.2 as the external tensor product of the evaluation arrows

$$DL_i \overset{\mathbf{L}}{\otimes} L_i \longrightarrow K_{X_i}.$$

In view of the Künneth isomorphism 2.2.4, one thus sees that 4.1.2 is a "perfect duality", i.e. identifies by the adjunction isomorphism 2.2.1 each of the complexes $DL_1 \overset{\mathbf{L}}{\otimes}_S L_2$ and $L_1 \overset{\mathbf{L}}{\otimes}_S DL_2$ with the dual of the other (with values in K_X).

When $X_1 = X_2 = S$, 4.1.3 is a special case of a pairing valid for perfect complexes on an arbitrary ringed topos (SGA 6 I 7.8), and, with the notation of (SGA 6 I 8.3), one has

$$\langle u, v\rangle = \mathrm{Tr}(vu) = \mathrm{Tr}(uv). \tag{4.1.5}$$

4.2

Let $c : C \to X$, $d : D \to X$, and $e = c \times_X d : E = C \times_X D \to X$. For $P, Q \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$, one has a canonical arrow (which is not in general an isomorphism)

$$c^!P \overset{\mathbf{L}}{\otimes}_X d^!Q \longrightarrow e^!(P \overset{\mathbf{L}}{\otimes} Q), \tag{4.2.1}$$

defined, in the same way as 1.7.3, as the adjoint of the composite arrow

$$e_!(c^!P \overset{\mathbf{L}}{\otimes}_X d^!Q) \underset{(1)}{\xrightarrow{\sim}} c_!c^!P \overset{\mathbf{L}}{\otimes} d_!d^!Q \xrightarrow{(2)} P \overset{\mathbf{L}}{\otimes} Q,$$

where (1) is the Künneth isomorphism (SGA 4 XVII 5.4.2.2) and (2) is the tensor product of the adjunction arrows. Applying $e_!$ to 4.2.1 and composing with the Künneth isomorphism just cited, one obtains a canonical arrow

$$c_!c^!P \overset{\mathbf{L}}{\otimes} d_!d^!Q \longrightarrow e_!e^!(P \overset{\mathbf{L}}{\otimes} Q). \tag{4.2.2}$$

Similarly, composing the Künneth arrow

$$c_*c^!P \overset{\mathbf{L}}{\otimes} d_*d^!Q \longrightarrow e_*(c^!P \overset{\mathbf{L}}{\otimes}_X d^!Q)$$

with the arrow deduced from 4.2.1 by applying e_*, one obtains a canonical arrow

$$c_*c^!P \overset{\mathbf{L}}{\otimes} d_*d^!Q \longrightarrow e_*e^!(P \overset{\mathbf{L}}{\otimes} Q). \tag{4.2.3}$$

For $P = DL_1 \overset{\mathbf{L}}{\otimes}_S L_2$, $Q = L_1 \overset{\mathbf{L}}{\otimes}_S DL_2$, one deduces from 4.2.2 and 4.2.3, by composition with 4.1.2 and the isomorphism $e^!K_X = K_E$, and with the identifications 3.1.1 and 3.2.1, pairings

$$c_!\mathrm{RHom}(c_1^*L_1, c_2^!L_2) \overset{\mathbf{L}}{\otimes} d_!\mathrm{RHom}(d_2^*L_2, d_1^!L_1) \longrightarrow e_!K_E, \tag{4.2.4}$$

$$c_*\mathrm{RHom}(c_1^*L_1, c_2^!L_2) \overset{\mathbf{L}}{\otimes} d_*\mathrm{RHom}(d_2^*L_2, d_1^!L_1) \longrightarrow e_*K_E, \tag{4.2.4'}$$

$$\langle\ ,\ \rangle : \mathrm{Hom}(c_1^*L_1, c_2^!L_2) \otimes \mathrm{Hom}(d_2^*L_2, d_1^!L_1) \longrightarrow \mathrm{H}^0(E, K_E). \tag{4.2.5}$$

These pairings are compatible with étale localization: given a commutative square (not necessarily cartesian)

if c', d', e' denote the composites $C' \to C \to X$, $D' \to D \to X$, $E' \to E \to X$, one has a commutative square.

$$\begin{array}{ccc} \mathrm{Hom}(c_1^* L_1, c_2^! L_2) \otimes \mathrm{Hom}(d_2^* L_2, d_1^! L_1) & \xrightarrow{4.2.5} & \mathrm{H}^0(E, K_E) \\ \downarrow & & \downarrow \\ \mathrm{Hom}(c_1'^* L_1, c_2'^! L_2) \otimes \mathrm{Hom}(d_2'^* L_2, d_1'^! L_1) & \longrightarrow & \mathrm{H}^0(E', K_{E'}) \end{array} \tag{4.2.6}$$

where the vertical arrows are the restrictions, and the lower horizontal arrow is the composite of the arrow analogous to 4.2.5 and the restriction

$$\mathrm{H}^0(E'', K_{E''}) \longrightarrow \mathrm{H}^0(E', K_{E'}),$$

with $E'' = C' \times_{X'} D'$ (there are analogous commutative squares with arrows of type 4.2.4, 4.2.4', which we leave to the reader to write down). If Z is étale over E, we shall denote, for

$$u \in \mathrm{Hom}(c_1^* L_1, c_2^! L_2), \qquad v \in \mathrm{Hom}(d_2^* L_2, d_1^! L_1),$$
$$\langle u, v \rangle_Z \in \mathrm{H}^0(Z, K_Z) \tag{4.2.7}$$

the image of $\langle u, v \rangle$ in $\mathrm{H}^0(Z, K_Z)$ by restriction (in practice, Z will be a connected component of E). If z is an isolated closed point of E, and $\bar{z}$ a geometric point above z, it follows from 4.2.6 that

$$\langle u, v \rangle_z \in \mathrm{H}^0(z, K_z) = A$$

depends only on the situation deduced by strict localization at the images of $\bar{z}$ in C, D, X.

Example 4.3. Assume that X_i is smooth, purely of relative dimension r_i, and that c and d are closed immersions, with c_2 (respectively d_1) finite. For $L_1 = A_{X_1}$, $L_2 = A_{X_2}$, we have, by 3.1.3,

$$DL_1 \otimes_S^{\mathbf{L}} L_2 = A_X(r_1)[2r_1], \qquad L_1 \otimes_S^{\mathbf{L}} DL_2 = A_X(r_2)[2r_2],$$

and 4.1.2 is identified with the product

$$A_X(r_1)[2r_1] \otimes^{\mathbf{L}} A_X(r_2)[2r_2] \longrightarrow A_X(r)[2r],$$

where $r = r_1 + r_2$, and hence, taking 3.2.1 into account, 4.2.5 is identified with the usual cup product

$$\mathrm{H}^{2r_1}_C(X, A(r_1)) \otimes \mathrm{H}^{2r_2}_D(X, A(r_2)) \longrightarrow \mathrm{H}^{2r}_{C \cap D}(X, A(r)).$$

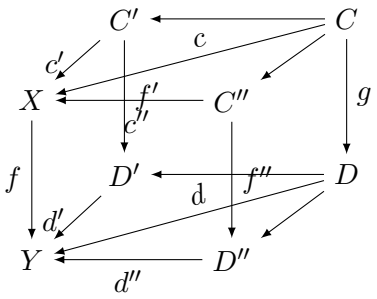
Take as cohomological correspondence from X_1 to X_2 (respectively from X_2 to X_1) the class of c (respectively d) (3.2 a)). It follows from (SGA $4^{1/2}$ Cycle 2.3.8) that, at an isolated point z of $C \cap D$, $\langle \mathrm{cl}(c), \mathrm{cl}(d) \rangle_z$ is nothing but the image in A of the intersection multiplicity of C and D at z.

We now give the main result of the exposé.

Theorem 4.4. Let, for $i = 1, 2$, $f_i : X_i \longrightarrow Y_i$ be a proper S-morphism,

$$f = f_1 \times_S f_2 : X \longrightarrow Y, \qquad p_i : X \longrightarrow X_i, \qquad q_i : Y \longrightarrow Y_i$$

the projections. Let moreover



(4.4.0)

be a commutative cube with cartesian horizontal faces, with c', c'', d', d'' proper. Put

$$c'_i = p_i c', \qquad c''_i = p_i c'', \qquad d'_i = q_i d', \qquad d''_i = q_i d''.$$

Finally, let $L_i \in \operatorname{ob} D_{\mathrm{ctf}}(X_i)$. Then there is a commutative square

$$\begin{array}{ccc} f_* c'_* \mathrm{RHom}({c'_1}^* L_1, {c'_2}^! L_2) \otimes^{\mathbf{L}} f_* c''_* \mathrm{RHom}({c''_2}^* L_2, {c''_1}^! L_1) & \xrightarrow{(1)} & f_* c_* K_C \\ \downarrow{\scriptstyle (2)} & & \downarrow{\scriptstyle (4)} \\ {d'_*}\mathrm{RHom}({d'_1}^* M_1, {d'_2}^! M_2) \otimes^{\mathbf{L}} {d''_*}\mathrm{RHom}({d''_2}^* M_2, {d''_1}^! M_1) & \xrightarrow[(3)]{} & d_* K_D, \end{array} \tag{4.4.1}$$

where $M_i = f_{i*} L_i$, (3) is given by 4.2.4, (1) is deduced from 4.2.4 by applying f_* and composing with the canonical arrow

$$f_* c'_*(-) \otimes^{\mathbf{L}} f_* c''_*(-) \longrightarrow f_*(c'_*(-) \otimes^{\mathbf{L}} c''_*(-)),$$

(2) is the tensor product of the arrows 3.7.5 relative to the faces containing f, and (4) is defined by the adjunction arrow $g_* K_C = g_! g^! K_D \longrightarrow K_D$.

Proof. Put

$$DL_1 \otimes^{\mathbf{L}}_S L_2 = P, \qquad L_1 \otimes^{\mathbf{L}}_S DL_2 = Q, \qquad DM_1 \otimes^{\mathbf{L}}_S M_2 = E, \qquad M_1 \otimes^{\mathbf{L}}_S DM_2 = F.$$

Consider the diagram

$$\begin{array}{ccccccc} f_* c'_* {c'}^! P \otimes^{\mathbf{L}} f_* c''_* {c''}^! Q & & \xrightarrow{(1)} & & f_* c_* c^! \big(P \otimes^{\mathbf{L}} Q\big) & \xrightarrow{(2)} & f_* c_* c^! K_X \\ \downarrow{\scriptstyle (8)} & & & & \downarrow{\scriptstyle (9)} & & \downarrow{\scriptstyle (10)} \\ {d'_*}{d'}^! f_* P \otimes^{\mathbf{L}} {d''_*}{d''}^! f_* Q & \xrightarrow[(3)]{} & d_* d^! \big(f_* P \otimes^{\mathbf{L}} f_* Q\big) & \xrightarrow[(4)]{} & d_* d^! f_* \big(P \otimes^{\mathbf{L}} Q\big) & \xrightarrow[(5)]{} & d_* d^! f_* K_X \\ \downarrow{\scriptstyle (11)} & & \downarrow{\scriptstyle (12)} & & & & \downarrow{\scriptstyle (13)} \\ {d'_*}{d'}^! E \otimes^{\mathbf{L}} {d''_*}{d''}^! F & \xrightarrow[(6)]{} & d_* d^! \big(E \otimes^{\mathbf{L}} F\big) & & \xrightarrow[(7)]{} & & d_* d^! K_Y, \end{array} \tag{4.4.2}$$

The arrows are as follows: (1) is deduced from 4.2.2 by applying f_*; (2) is defined by 4.1.2; (3) is given by 4.2.2; (4) is given by the canonical arrow $f_*P \otimes^{\mathbf{L}} f_*Q \longrightarrow f_*(P \otimes^{\mathbf{L}} Q)$; (5) by 4.1.2; (6) by 4.2.2; (7) by 4.1.2; (8) is the tensor product of arrows 3.7.3; (9) and (10) are defined by 3.7.3; (11) and (12) by the isomorphisms $f_*P \longrightarrow E$, $f_*Q \longrightarrow F$ (3.3.1); and (13) by the adjunction arrow $f_*K_X \longrightarrow K_Y$. By definition, 4.4.1 is identified, via 3.1.1 and 3.2.1, with the outer boundary of 4.4.2. It remains only to prove that the squares (A), (B), (C), (D) are commutative. The commutativity of (B) and (C) is clear by functoriality. It remains to prove that of (A) and (D).

a) Commutativity of (D). It is enough to prove that the square

$$\begin{array}{ccc} f_*P \otimes^{\mathbf{L}} f_*Q & \longrightarrow & f_*K_X \\ \downarrow & & \downarrow \\ E \otimes^{\mathbf{L}} F & \longrightarrow & K_Y \end{array} \tag{4.4.3}$$

(corresponding to (D) for $d = \mathrm{Id}$) commutes. Recall that the pairing

$$P \otimes^{\mathbf{L}} Q \longrightarrow K_X \quad (\text{respectively } E \otimes^{\mathbf{L}} F \longrightarrow K_Y)$$

is the external tensor product of the evaluation arrows

$$DL_i \otimes^{\mathbf{L}} L_i \longrightarrow K_{X_i} \quad (\text{respectively } DM_i \otimes^{\mathbf{L}} M_i \longrightarrow K_{Y_i}).$$

By the Künneth isomorphisms

$$f_{1*}DL_1 \otimes^{\mathbf{L}}_S f_{2*}L_2 \xrightarrow{\sim} f_*P, \qquad f_{1*}L_1 \otimes^{\mathbf{L}}_S f_{2*}DL_2 \xrightarrow{\sim} f_*Q,$$

4.4.3 is therefore identified with the external tensor product of the squares

$$\begin{array}{ccc} f_{i*}DL_i \otimes^{\mathbf{L}} f_{i*}L_i & \xrightarrow{(1)} & f_{i*}K_{X_i} \\ {\scriptstyle (3)}\downarrow & & \downarrow{\scriptstyle (4)} \\ DM_i \otimes^{\mathbf{L}} M_i & \xrightarrow[(2)]{} & K_{Y_i}, \end{array} \tag{4.4.4}$$

where (2) is the evaluation arrow, (1) the composite of the canonical arrow

$$f_{i*}DL_i \otimes^{\mathbf{L}} f_{i*}L_i \longrightarrow f_{i*}(DL_i \otimes^{\mathbf{L}} L_i)$$

and the arrow defined by the evaluation arrow, (3) is the tensor product of the duality isomorphism $f_{i*}DL_i \longrightarrow DM_i$ and the identity arrow of M_i, and (4) is the adjunction arrow. It is therefore enough to verify the commutativity of the squares 4.4.4. Since the above duality isomorphism is the composite of the canonical arrow (SGA 4 XVIII 3.1.9.5)

$$f_{i*}\mathrm{RHom}(L_i, K_{X_i}) \longrightarrow \mathrm{RHom}(f_{i*}L_i, f_{i*}K_{X_i})$$

and the arrow deduced from the adjunction arrow

$$f_{i*}K_{X_i} \longrightarrow K_{Y_i},$$

it is enough to see that the following square commutes:

$$\begin{array}{ccc} f_{i*}\mathrm{RHom}(L_i, K_{X_i}) \otimes^{\mathbf{L}} f_{i*}L_i & \xrightarrow{(1)} & f_{i*}K_{X_i} \\ \downarrow{\scriptstyle (3)} & & \downarrow{\scriptstyle \mathrm{Id}} \\ \mathrm{RHom}(f_{i*}L_i, f_{i*}K_{X_i}) \otimes^{\mathbf{L}} f_{i*}L_i & \xrightarrow[(2)]{} & f_{i*}K_{X_i}, \end{array} \tag{4.4.5}$$

where (1) is the arrow (1) of 4.4.4, (2) the evaluation arrow, and (3) the tensor product by $f_{i*}L_i$ of the canonical arrow just mentioned. More generally, for any arrow $N_i \longrightarrow f_{i*}L_i$ in $D_{\mathrm{ctf}}(X_i)$, i.e. any arrow $L_i \xrightarrow{u} N_i$ of type 1 over f_i, the triangle

$$\begin{array}{ccc} f_{i*}\mathrm{RHom}(L_i, K_{X_i}) \otimes^{\mathbf{L}} N_i & & \\ \downarrow & \searrow & \\ \mathrm{RHom}(N_i, f_{i*}K_{X_i}) \otimes^{\mathbf{L}} N_i & \longrightarrow & f_{i*}K_{X_i} \end{array}$$

deduced from 4.4.5 commutes: indeed, by functoriality, one may assume that $L_i = f_i^* N_i$, with u given by the identity of L_i; the arrow

$$f_{i*}\mathrm{RHom}(L_i, K_{X_i}) \longrightarrow \mathrm{RHom}(N_i, f_{i*}K_{X_i})$$

is then the inverse of the trivial duality isomorphism, and the commutativity of the triangle is verified immediately at the level of complexes, resolving N_i flatly and K_{X_i} injectively.

b) Commutativity of (A). Referring to the definition of 3.7.3, one sees that it is enough to verify this commutativity in each of the following cases:

(i) $X_i = Y_i$, $f_i =$ the identity arrow of X_i; (ii) the lateral faces of 4.4.0 are cartesian.

Place ourselves in case (i). The square (A) is the outer boundary of the diagram

$$\begin{array}{ccccc} c'_*c'^!P \otimes^{\mathbf{L}} c''_*c''^!Q & \xrightarrow{\sim} & c_*(c'^!P \otimes^{\mathbf{L}}_X c''^!Q) & \longrightarrow & c_*c^!(P \otimes^{\mathbf{L}} Q) \\ \downarrow{\scriptstyle (8)} & A_1 & \downarrow & A_2 & \downarrow{\scriptstyle (9)} \\ d'_*d'^!P \otimes^{\mathbf{L}} d''_*d''^!Q & \xrightarrow[\sim]{} & d_*(d'^!P \otimes^{\mathbf{L}}_X d''^!Q) & \longrightarrow & d_*d^!(P \otimes Q), \end{array}$$

in which the horizontal isomorphisms of A_1 are Künneth isomorphisms, the horizontal arrows of A_2 are given by 4.2.1, and the middle vertical arrow is deduced by applying d_* to the arrow

$$g_!(c'^!P \otimes^{\mathbf{L}}_X c''^!Q) \longrightarrow d'^!P \otimes^{\mathbf{L}}_X d''^!Q$$

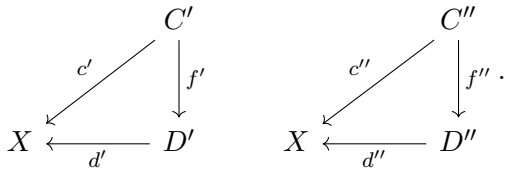
defined, via Künneth, by the external tensor product of the adjunction arrows

$$f'_!c'^!P \longrightarrow d'^!P, \qquad f''_!c''^!Q \longrightarrow d''^!Q.$$

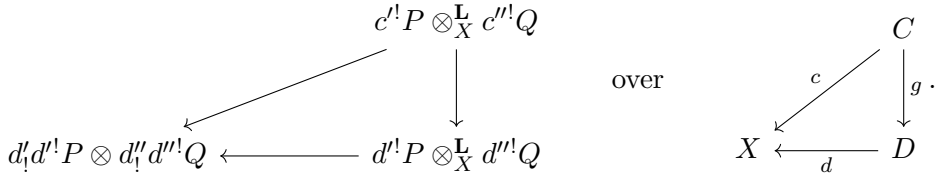
These adjunction arrows and the identity arrows of $d'_!d'^!P$, $d''_!d''^!Q$ define commutative triangles of arrows of type 3 (1.4)

$$\begin{array}{ccc} & c'^!P & \\ \swarrow & \downarrow & \\ d'_!d'^!P & \longleftarrow & d'^!P \end{array} \qquad \begin{array}{ccc} & c''^!Q & \\ \swarrow & \downarrow & \\ d''_!d''^!Q & \longleftarrow & d''^!Q \end{array}$$

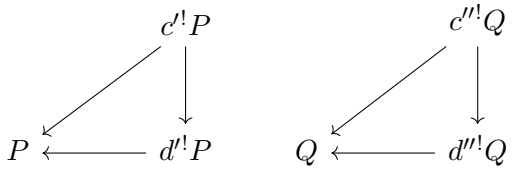
over



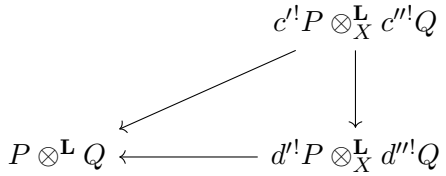
By external tensor product (over X), these triangles give a commutative triangle



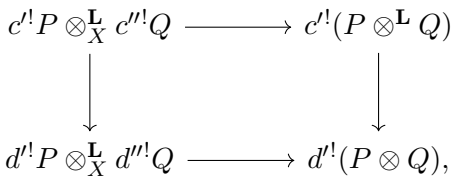
The commutativity of this triangle is equivalent to that of the square deduced from A_1 by inverting the horizontal arrows. On the other hand, there are commutative triangles of arrows of type 3



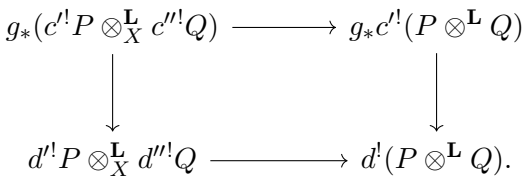
defined by the identity arrows of $d'^!P$, $c'^!P$, $d''^!Q$, $c''^!Q$. By external tensor product, one obtains a commutative triangle



which can be interpreted as a morphism of arrows of type 3 over $g : C \longrightarrow D$:



or again as a commutative square over D:



But the square deduced from the latter by applying d_* is none other than A_2, whence the commutativity of (A) in case (i).

It remains to treat case (ii). Since the faces of 4.4.0 containing f are cartesian, the arrows

$$f'_*c'^!P \longrightarrow d'^!f_*P, \qquad f''_*c''^!Q \longrightarrow d''^!f_*Q$$

(3.7.3) are isomorphisms. Their inverses define arrows of type 1

$$c'^!P \longrightarrow d'^!f_*P, \qquad c''^!Q \longrightarrow d''^!f_*Q$$

over f', f'', whence, by direct image, commutative squares of arrows of type 1

$$\begin{array}{ccc} c'_*c'^!P & \longleftarrow & c'^!P \\ \downarrow & & \downarrow \\ d'_*d'^!P & \longleftarrow & d'^!f_*P \end{array} \qquad \begin{array}{ccc} c''_*c''^!Q & \longleftarrow & c''^!Q \\ \downarrow & & \downarrow \\ d''_*d''^!Q & \longleftarrow & d''^!f_*Q \end{array}$$

over the faces of 4.4.0 containing f. Taking the tensor product, one obtains a commutative square in $D_{\mathrm{ctf}}(Y)$

$$\begin{array}{ccc} d'_*d'^!f_*P \otimes^{\mathbf{L}} d''_*d''^!f_*Q & \longrightarrow & d_*\big(d'^!f_*P \otimes^{\mathbf{L}}_Y d''^!f_*Q\big) \\ \downarrow & & \downarrow \\ f_*c'_*c'^!P \otimes^{\mathbf{L}} f_*c''_*c''^!Q & \longrightarrow & d_*g_*\big(c'^!P \otimes^{\mathbf{L}}_X c''^!Q\big), \end{array} \tag{4.4.6}$$

where the left vertical arrow is the inverse of (8), the horizontal arrows are given by Künneth, and the right vertical arrow by the external tensor product over Y of the arrows

$$f'_*c'^!P \longrightarrow d'^!f_*P, \qquad f''_*c''^!Q \longrightarrow d''^!f_*Q.$$

The same tensor product defines the left vertical arrow of the square

$$\begin{array}{ccc} d'^!f_*P \otimes^{\mathbf{L}}_Y d''^!f_*Q & \longrightarrow & d^!f_*(P \otimes^{\mathbf{L}} Q) \\ \downarrow & & \downarrow \\ g_*(c'^!P \otimes^{\mathbf{L}}_X c''^!Q) & \longrightarrow & g_*c'^!(P \otimes^{\mathbf{L}} Q), \end{array} \tag{4.4.7}$$

where the right vertical arrow is 3.7.3, and the horizontal arrows are defined by 4.2.1. The outer boundary of the diagram composed of 4.4.6 and d_*(4.4.7) is the square deduced from (A) by inverting the vertical arrows. It is therefore enough to prove that 4.4.7 commutes, in other words that the arrows 4.2.1

$$c'^!P \otimes^{\mathbf{L}}_X c''^!Q \longrightarrow c'^!(P \otimes^{\mathbf{L}} Q), \qquad d'^!f_*P \otimes^{\mathbf{L}}_Y d''^!f_*Q \longrightarrow d^!f_*(P \otimes^{\mathbf{L}} Q)$$

define a morphism from

$$c'^!P \otimes^{\mathbf{L}}_X c''^!Q \longrightarrow d'^!f_*P \otimes^{\mathbf{L}}_Y d''^!f_*Q$$

to

$$c'^!(P \otimes^{\mathbf{L}} Q) \longrightarrow d^!f_*(P \otimes^{\mathbf{L}} Q),$$

viewed as arrows of type 1 over g. By adjunction, we are reduced to verifying that the tensor products of adjunction arrows

$$c'_*c'^!P \otimes^{\mathbf{L}}_X c''_*c''^!Q \longrightarrow P \otimes^{\mathbf{L}} Q, \qquad d'_*d'^!f_*P \otimes^{\mathbf{L}}_Y d''_*d''^!f_*Q \longrightarrow f_*P \otimes^{\mathbf{L}} f_*Q$$

define a morphism, between arrows of type 1 over f, from the tensor product of the arrows

$$c'_*c'^!P \longrightarrow d'_*d'^!f_*P, \qquad c''_*c''^!Q \longrightarrow d''_*d''^!f_*Q$$

to the tensor product of the arrows

$$P \longrightarrow f_*P, \qquad Q \longrightarrow f_*Q.$$

For this it is enough to verify that the adjunction arrows

$$c'_*c'^!P \longrightarrow P, \qquad d'_*d'^!f_*P \longrightarrow f_*P$$

define a morphism from

$$c'_*c'^!P \longrightarrow d'_*d'^!f_*P$$

to

$$P \longrightarrow f_*P,$$

and likewise for the pair (c'', d''). It is enough to consider the case of (c', d'), the statement being the same in the two cases. We have to see that the triangle

$$\begin{array}{ccc} & & f_*c'_*c'^!P \\ & \swarrow & \downarrow \sim \\ f_*P & \longleftarrow & d'_*d'^!f_*P \end{array}$$

where the horizontal and oblique arrows are given by adjunction and the vertical arrow by the isomorphism 3.7.3, is commutative. Taking into account the definition of 3.7.3 (SGA 4 XVIII 3.1.12.3) as the transpose of a base-change isomorphism, we are reduced, by applying the functor $\mathrm{Hom}(R, -)$ $(R \in \mathrm{ob}\, D_{\mathrm{ctf}}(Y))$, to verifying the commutativity of the square

$$\begin{array}{ccc} c'_*c'^*f^*R & \xrightarrow{\mathrm{Id}} & c'_*f'^*d'^*R \\ \uparrow & & \uparrow \sim \\ f^*R & \longrightarrow & f^*d'_*d'^*R \end{array}$$

where the left vertical arrow (respectively the lower horizontal arrow) is defined by the adjunction arrow $1 \longrightarrow c'_*c'^*$ (respectively $1 \longrightarrow d'_*d'^*$), and the right vertical arrow by the base-change isomorphism

$$f^*d'_* \xrightarrow{\sim} c'_*f'^*.$$

But this square commutes by the very definition of the base-change arrow. The commutativity of (A) is therefore established, and this completes the proof of the theorem.

Corollary 4.5. Under the hypotheses of 4.4, there is a commutative square

$$\begin{array}{ccc} \mathrm{Hom}(c'_1{}^*L_1, c'_2{}^!L_2) \otimes \mathrm{Hom}(c''_2{}^*L_2, c''_1{}^!L_1) & \xrightarrow{4.2.5} & \mathrm{H}^0(C, K_C) \\ \downarrow{\scriptstyle 3.7.6 \otimes 3.7.6} & & \downarrow{\scriptstyle g_*} \\ \mathrm{Hom}(d'_1{}^*f_{1*}L_1, d'_2{}^!f_{2*}L_2) \otimes \mathrm{Hom}(d''_2{}^*f_{2*}L_2, d''_1{}^!f_{1*}L_1) & \xrightarrow[4.2.5]{} & \mathrm{H}^0(D, K_D), \end{array}$$

where g_* is defined by the adjunction arrow

$$g_*K_C = g_*g^!K_D \longrightarrow K_D.$$

In other words, for

$$u \in \mathrm{Hom}({c'_1}^*L_1, {c'_2}^!L_2), \qquad v \in \mathrm{Hom}({c''_2}^*L_2, {c''_1}^!L_1),$$

one has

$$\langle f_*u, f_*v\rangle = g_*\langle u, v\rangle. \tag{4.5.1}$$

For every proper S-scheme $t : T \longrightarrow S$, denote by

$$\int_T : \mathrm{H}^0(T, K_T) \longrightarrow \mathrm{H}^0(S, K_S) = \mathrm{H}^0(S, A) \tag{4.6}$$

the arrow defined by the adjunction arrow

$$t_!K_T \longrightarrow A.$$

Corollary 4.7 – Lefschetz–Verdier formula. Under the hypotheses of 4.4, suppose that $Y_1 = Y_2 = S = D' = D''$. For

$$u \in \mathrm{Hom}({c'_1}^*L_1, {c'_2}^!L_2), \qquad v \in \mathrm{Hom}({c''_2}^*L_2, {c''_1}^!L_1),$$

one has

$$\langle u_*, v_*\rangle = \int_C \langle u, v\rangle, \tag{4.7.1}$$

where

$$u_* \in \mathrm{Hom}(f_{1*}L_1, f_{2*}L_2), \qquad v_* \in \mathrm{Hom}(f_{2*}L_2, f_{1*}L_1)$$

are the homomorphisms deduced from u, v by direct image over S (3.7.6), and

$$\langle u_*, v_*\rangle = \mathrm{Tr}(u_*v_*) = \mathrm{Tr}(v_*u_*)$$

is the cup product, in the sense of (SGA 6 I 8.3), of the homomorphisms of perfect complexes u_*, v_* (4.1.5).

Taking 3.6.5 into account, in particular one has:

Corollary 4.8. Let $t : T \longrightarrow S$ be a proper S-scheme, $\Delta \subset T \times_S T$ the diagonal, $F : T \longrightarrow T$ an S-endomorphism of T, $T^F = (\text{graph of } F) \times_{(T\times_S T)} \Delta$ the scheme of fixed points of F, $L \in \mathrm{ob}\, D_{\mathrm{ctf}}(T)$, $u \in \mathrm{Hom}(F^*L, L)$ a correspondence from L to L with support in the graph of F, and $1 \in \mathrm{Hom}(L, L)$ the identity correspondence, with support in Δ (3.2 b)). Then

$$\mathrm{Tr}(u_*) = \int_{T^F} \langle u, 1\rangle,$$

where u_* is the endomorphism of t_*L obtained by composing $t_*L \longrightarrow t_*F^*L$ (inverse image) with $t_*u : t_*F^*L \longrightarrow t_*L$.

From the remarks of 3.2 a) and 3.6 one also deduces:

Corollary 4.9. Under the hypotheses of 4.7, assume that X_i is smooth over S, purely of relative dimension r_i, and that C' (respectively C'') is a closed subscheme of X finite and of finite tor-dimension over X_2 (respectively X_1). Let

$$\mathrm{cl}(C') \in \mathrm{H}^{2r_1}_{C'}(X, A(r_1)), \qquad \mathrm{cl}(C'') \in \mathrm{H}^{2r_2}_{C''}(X, A(r_2))$$

be the cohomology classes of C' and C'', and let

$$\mathrm{cl}(C')_* \in \mathrm{Hom}(\mathrm{R}f_{1*}A, \mathrm{R}f_{2*}A), \qquad \mathrm{cl}(C'')_* \in \mathrm{Hom}(\mathrm{R}f_{2*}A, \mathrm{R}f_{1*}A)$$

be the corresponding homomorphisms (3.2 a), 3.7.6). Then

$$\langle \mathrm{cl}(C')_*, \mathrm{cl}(C'')_* \rangle = \int_{C' \cap C''} \mathrm{cl}(C)\,\mathrm{cl}(D),$$

where

$$\mathrm{cl}(C)\,\mathrm{cl}(D) \in \mathrm{H}^{2(r_1+r_2)}_{C' \cap C''}(X, A(r_1+r_2)) = \mathrm{H}^0(C' \cap C'', K_{C' \cap C''})$$

is the usual cup product.

Taking 4.3 into account, in particular one has:

Corollary 4.10. Under the hypotheses of 4.9, suppose that $C' \cap C''$ is finite. For $z \in C' \cap C''$, denote by $(C' \cdot C'')_z$ the image in A of the intersection multiplicity of C' and C'' at z. Then

$$\langle \mathrm{cl}(C')_*, \mathrm{cl}(C'')_* \rangle = \sum_{z \in C' \cap C''} (C' \cdot C'')_z.$$

4.11. Under the hypotheses of 4.9, one has in general

$$\langle \mathrm{cl}(C')_*, \mathrm{cl}(C'')_* \rangle = \sum_{Z \in \pi_0(C' \cap C'')} (\mathrm{cl}(C')\,\mathrm{cl}(C''))_Z, \tag{4.11.1}$$

where $\pi_0(C' \cap C'')$ denotes the set of connected components of $C' \cap C''$, and $(\mathrm{cl}(C')\,\mathrm{cl}(C''))_Z$ the restriction of $\mathrm{cl}(C')\,\mathrm{cl}(C'')$ to $\mathrm{H}^0(Z, K_Z)$. When Z is a component of dimension ≥ 1, the calculation of $(\mathrm{cl}(C')\,\mathrm{cl}(C''))_Z$ presents problems, because one is in an "excess" situation. If Z is smooth, purely of dimension d, if C' and C'' are smooth in a neighbourhood of Z, and if X is projective, one can show that

$$\int_Z (\mathrm{cl}(C')\,\mathrm{cl}(C''))_Z = \int_Z c_d(N_Z), \tag{4.11.2}$$

where N_Z is the locally free sheaf of rank d defined by the exact sequence of normal bundles

$$0 \longrightarrow N_{Z/C'} \oplus N_{Z/C''} \longrightarrow N_{Z/X} \longrightarrow N_Z \longrightarrow 0,$$

and $c_d(N_Z) \in \mathrm{H}^{2d}(Z, A(d))$ denotes its d-th Chern class (SGA 5 VII) (use (SGA 6 XIV 6.3) to reduce to a calculation of intersection number in K-theory, and apply (SGA 6 VII 2.5), cf. ([10] 4.1); the projectivity hypothesis is no doubt unnecessary).

Let T be a smooth projective S-scheme; take as correspondence C' (respectively C'') the graph of an S-endomorphism F (respectively the diagonal), and suppose that the scheme of fixed points $T^F = C' \cap C''$ is smooth. The sheaf $N_{(T^F)}$ above is nothing other than the tangent sheaf to T^F, so

that 4.11.2 implies, by the Gauss–Bonnet formula (SGA 5 VII 4.9), the analogue of a formula well known to topologists:

$$\mathrm{Tr}(F, \mathrm{R}\Gamma(T, A)) = \mathrm{EP}(T^F), \tag{4.11.3}$$

where $\mathrm{EP}(T^F)$ denotes the Euler–Poincaré characteristic of T_s^F, for s a geometric point above S (loc. cit.).

The calculation of $(\mathrm{cl}(C')\,\mathrm{cl}(C''))_Z$ for a non-smooth component Z of dimension ≥ 1 has not been treated in general, at least to the knowledge of the editor.

4.12. In the situation of 4.7, let z be an isolated point of C, with projection z_i on X_i, a' (respectively a'') on C' (respectively C''), and let $\bar{z}$ be a geometric point above z, with image $\bar{z}_i$ above z_i. Assume that c_2' (respectively c_1'') is quasi-finite and flat at a' (respectively a''), that L_i is perfect in a neighbourhood of $\bar{z}_i$, and that u (respectively v) is given in a neighbourhood of a' (respectively a'') by

$$\mathrm{Tr}_{c_2'} : c_{2!}' {c_2'}^* L_2 \longrightarrow L_2 \quad \text{and} \quad s \in \mathrm{Hom}({c_1'}^* L_1, {c_2'}^* L_2)$$

(respectively

$$\mathrm{Tr}_{c_1''} : c_{1!}'' {c_1''}^* L_1 \longrightarrow L_1 \quad \text{and} \quad t \in \mathrm{Hom}({c_2''}^* L_2, {c_1''}^* L_1)).$$

Let $s_{\bar{z}} \in \mathrm{Hom}(L_{1\bar{z}_1}, L_{2\bar{z}_2})$ (respectively $t_{\bar{z}} \in \mathrm{Hom}(L_{2\bar{z}_2}, L_{1\bar{z}_1})$) be the homomorphism deduced from s (respectively t) by passage to the fibres. Let again, as in 3.2 a), $\mathrm{cl}(c')$ (respectively $\mathrm{cl}(c'')$) denote the correspondence from X_1 to X_2 (respectively from X_2 to X_1) defined, in a neighbourhood of a' (respectively a''), by c_2' (respectively c_1''), and let $(C' \cdot C'')_z$ be the corresponding local term $\langle \mathrm{cl}(c'), \mathrm{cl}(c'') \rangle_z$ (equal to the image in A of the intersection multiplicity of C' and C'' at z when C' and C'' are closed subschemes of X, with X_1 and X_2 smooth). Then:

$$\langle u, v \rangle_z = (C' \cdot C'')_z \langle s_{\bar{z}}, t_{\bar{z}} \rangle. \tag{4.12.1}$$

This follows easily from 4.2.6.

4.13. If T is a scheme over S, denote by $DF(T)$ the filtered derived category of complexes of A_T-modules with finite filtration ([9] V 1), and by $DF_{\mathrm{ctf}}(T)$ the full subcategory formed by the L such that $\mathrm{gr}(L) \in \mathrm{ob}\, D_{\mathrm{ctf}}(T)$. The kind of compatibility of filtered derived functors with passage to associated graded objects implies that DF_{ctf} is stable under the six operations f^*, f_*, $f_!$, $f^!$, $\otimes^{\mathbf{L}}$, RHom. The definitions and results of the preceding numbers are valid, mutatis mutandis, in DF_{ctf}. The pairing 4.1.2 is compatible with passage to associated graded objects (K_X being regarded as endowed with the trivial filtration), and it follows that, with the notation of 4.2.5, for $L_i \in \mathrm{ob}\, DF_{\mathrm{ctf}}(X_i)$,

$$u \in \mathrm{Hom}_{DF}(c_1^* L_1, c_2^! L_2), \qquad v \in \mathrm{Hom}_{DF}(d_2^* L_2, d_1^! L_1),$$

one has the following equality in $\mathrm{H}^0(E, K_E)$:

$$\langle u, v \rangle = \sum_i \langle \mathrm{gr}^i u, \mathrm{gr}^i v \rangle. \tag{4.13.1}$$

As Deligne observes, this remark applies in particular to the situation considered by Langlands in ([13] §7). The correspondences that he considers in (loc. cit. 7.11) indeed preserve, near the fixed points, finite filtrations on the sheaves with associated graded objects inducing, on the strict localization at the image of a fixed point, either a constant sheaf or a constant sheaf on

the complement of the closed point extended by zero. The calculation of the local terms is easily reduced, by 4.13, to 4.12.1 and to the case of sheaves concentrated on the closed points that are the images of the fixed points, a case treated directly. Applying 4.7, one obtains the Lefschetz formula required in ([13] 7.11). We point out that the general statement (loc. cit. 7.12) is true; the proof, more delicate, will be given in III B.

5. Complements

5.1. Dual of a correspondence

Let, for $i = 1, 2$, X_i be an S-scheme, let $X = X_1 \times_S X_2$, and let $p_i : X \to X_i$ be the projections. Let $L_i \in \operatorname{ob} D_{\mathrm{ctf}}(X_i)$. Every cohomological correspondence u from L_1 to L_2 gives, by applying D_X and identifying $Dp_2^!$ with $p_2^* D$ and Dp_1^* with $p_1^! D$, a correspondence Du from DL_2 to DL_1, called the *dual of* u. In other words, D defines a homomorphism

$$D : \operatorname{Hom}(p_1^* L_1, p_2^! L_2) \longrightarrow \operatorname{Hom}(p_2^* DL_2, p_1^! DL_1). \tag{5.1.1}$$

One checks that 5.1.1 is obtained, by applying $H^0(X, -)$, from the isomorphism

$$D : \operatorname{RHom}(p_1^* L_1, p_2^! L_2) \xrightarrow{\sim} \operatorname{RHom}(p_2^* DL_2, p_1^! DL_1) \tag{5.1.2}$$

which makes the square

$$\begin{array}{ccc} p_1^* DL_1 \otimes^{\mathbf{L}} p_2^* L_2 & \xrightarrow{3.1.1} & \operatorname{RHom}(p_1^* L_1, p_2^! L_2) \\ \downarrow & & \downarrow \\ p_2^* DDL_2 \otimes^{\mathbf{L}} p_1^* DL_1 & \xrightarrow{3.1.1} & \operatorname{RHom}(p_2^* DL_2, p_1^! DL_1), \end{array} \tag{5.1.3}$$

commutative. Here the left vertical arrow is the composite of the symmetry isomorphism and the one defined by the biduality isomorphism $L_2 \to DDL_2$. It follows easily from the definitions that the following square is commutative:

$$\begin{array}{ccc} \operatorname{RHom}_S(L_1, L_2) \otimes^{\mathbf{L}} \operatorname{RHom}_S(L_2, L_1) & \xrightarrow{4.1.3} & K_X \\ \downarrow{\scriptstyle D \otimes^{\mathbf{L}} D} & & \downarrow{\scriptstyle \mathrm{Id}} \\ \operatorname{RHom}_S(DL_2, DL_1) \otimes^{\mathbf{L}} \operatorname{RHom}_S(DL_1, DL_2) & \xrightarrow{4.1.3} & K_X. \end{array} \tag{5.1.4}$$

Let $c : C \to X$ be an S-morphism and put $c_i = p_i c$. Applying $c_* c^!$ to 5.1.2, and using (3.2.1), one deduces an isomorphism

$$D : \operatorname{Hom}(c_1^* L_1, c_2^! L_2) \xrightarrow{\sim} \operatorname{Hom}(c_2^* DL_2, c_1^! DL_1), \tag{5.1.5}$$

which is checked to identify with the one obtained by applying the functor D_X and the identifications of Dc_1^* with $c_1^! D$ and $Dc_2^!$ with $c_2^* D$. If $c' : C' \to X$ and $c'' : C'' \to X$ are S-morphisms, it follows from 5.1.4 that, for

$$u \in \operatorname{Hom}({c'_1}^* L_1, {c'_2}^! L_2), \qquad v \in \operatorname{Hom}({c''_2}^* L_2, {c''_1}^! L_1),$$

one has

$$\langle u, v\rangle = \langle Du, Dv\rangle, \tag{5.1.6}$$

with the notation of 4.2.5.

On the other hand, one checks that, in the situation of 3.3, the following square is commutative:

$$\begin{array}{ccc} f_*\mathrm{RHom}_S(L_1, L_2) & \xrightarrow{3.3.1} & \mathrm{RHom}_S(f_{1!}L_1, f_{2*}L_2) \\ {\scriptstyle f_*D}\downarrow & & \downarrow{\scriptstyle D} \\ f_*\mathrm{RHom}_S(DL_2, DL_1) & \xrightarrow{3.3.1} & \mathrm{RHom}_S(f_{2!}DL_2, f_{1*}DL_1), \end{array} \tag{5.1.7}$$

and consequently, in the situation of 3.7.6, one has

$$f_*Du = Df_*u. \tag{5.1.8}$$

5.2. Composition of correspondences

Let, for $i = 1, 2, 3$, X_i be an S-scheme, let $X_{ij} = X_i \times_S X_j$, $X = X_1 \times_S X_2 \times_S X_3$, and let $p_i : X \to X_i$, $p_{ij} : X \to X_{ij}$ be the projections. Let $L_i \in \mathrm{ob}\, D_{\mathrm{ctf}}(X_i)$. One has $X = X_{12} \times_{X_2} X_{23}$, and

$$(DL_1 \otimes^{\mathbf{L}}_S L_2) \otimes^{\mathbf{L}}_{X_2} (DL_2 \otimes^{\mathbf{L}}_S L_3) = p_1^*DL_1 \otimes^{\mathbf{L}} p_2^*L_2 \otimes^{\mathbf{L}} p_2^*DL_2 \otimes^{\mathbf{L}} p_3^*L_3.$$

The evaluation arrow $L_2 \otimes^{\mathbf{L}} DL_2 \to K_{X_2}$ therefore defines a pairing

$$(DL_1 \otimes^{\mathbf{L}}_S L_2) \otimes^{\mathbf{L}}_{X_2} (DL_2 \otimes^{\mathbf{L}}_S L_3) \longrightarrow p_{13}^!(DL_1 \otimes^{\mathbf{L}}_S L_3), \tag{5.2.1}$$

the second member being identified with $(DL_1 \otimes^{\mathbf{L}}_S L_3) \otimes^{\mathbf{L}}_S K_{X_2}$ by Künneth (1.7.3). Taking 3.1.1 and 3.1.2 into account, one may rewrite 5.2.1 in the form

$$\mathrm{RHom}_S(L_1, L_2) \otimes^{\mathbf{L}}_{X_2} \mathrm{RHom}_S(L_2, L_3) \longrightarrow p_{13}^!\mathrm{RHom}_S(L_1, L_3) = \mathrm{RHom}(p_1^*L_1, p_3^!L_3), \tag{5.2.2}$$

the identification with the second member being given by the induction isomorphism (SGA 4 XVIII 3.1.12.2). Hence one obtains a pairing, called *composition of correspondences*,

$$\mathrm{Hom}_S(L_1, L_2) \otimes \mathrm{Hom}_S(L_2, L_3) \longrightarrow \mathrm{Hom}(p_1^*L_1, p_3^!L_3), \tag{5.2.3}$$

which will be denoted $(u, v) \mapsto vu$. One checks that, if $p_{ij,i} : X_{ij} \to X_i$ and $p_{ij,j} : X_{ij} \to X_j$ denote the projections, 5.2.2 can also be obtained by composing the arrow

$$\mathrm{RHom}_S(L_1, L_2) \otimes^{\mathbf{L}}_{X_2} \mathrm{RHom}_S(L_2, L_3) \longrightarrow \mathrm{RHom}(p_1^*L_1, p_{12}^*p_{12,2}^!L_2) \otimes \mathrm{RHom}(p_{23}^!p_{23,2}^*L_2, p_3^!L_3)$$

(the tensor product of the canonical arrows $p_{12}^*\mathrm{RHom}_S(L_1, L_2) \to \mathrm{RHom}(p_1^*L_1, p_{12}^*p_{12,2}^!L_2)$ and $p_{23}^*\mathrm{RHom}_S(L_2, L_3) \to \mathrm{RHom}(p_{23}^!p_{23,2}^*L_2, p_3^!L_3)$), the arrow defined by the base-change arrow $p_{12}^!p_{12,2}^*L_2 \to p_{23}^*p_{23,2}^*L_2$, and a usual composition arrow on the RHom's.

Let $c' : C' \to X_{12}$ and $c'' : C'' \to X_{23}$ be correspondences, and let $c : C = C' \times_{X_2} C'' \to X$ be the "composite" correspondence. From 5.2.2 one deduces, or else defines directly by a composition analogous to the one just described, a pairing

$$\mathrm{RHom}({c'_1}^*L_1, {c'_2}^!L_2) \otimes^{\mathbf{L}}_{X_2} \mathrm{RHom}({c''_2}^*L_2, {c''_3}^!L_3) \longrightarrow \mathrm{RHom}(c_1^*L_1, c_3^!L_3), \tag{5.2.4}$$

hence a "composition" pairing $(u, v) \mapsto vu$:

$$\mathrm{Hom}({c'_1}^* L_1, {c'_2}^! L_2) \otimes \mathrm{Hom}({c''_2}^* L_2, {c''_3}^! L_3) \longrightarrow \mathrm{Hom}(c_1^* L_1, c_3^! L_3). \tag{5.2.5}$$

One checks that composition of correspondences is compatible with direct images in the following sense. Let, for $1 \leq i \leq 3$, $f_i : X_i \to Y_i$ be an S-morphism, with f_2 proper, and let c', c'', c be morphisms as above, with c' and c'' proper. Let $d' : D' \to Y_{12}$ and $d'' : D'' \to Y_{23}$ be proper morphisms, $d : D = D' \times_{Y_2} D'' \to Y$, and suppose given the commutative squares

$$\begin{array}{ccc} X_{12} & \longleftarrow & C' \\ {\scriptstyle f_{12}}\downarrow & & \downarrow \\ Y_{12} & \longleftarrow & D' \end{array} \qquad \begin{array}{ccc} X_{23} & \longleftarrow & C'' \\ {\scriptstyle f_{23}}\downarrow & & \downarrow \\ Y_{23} & \longleftarrow & D'' \end{array}$$

Then one has a commutative square

$$\begin{array}{ccc} \mathrm{Hom}({c'_1}^* L_1, {c'_2}^! L_2) \otimes \mathrm{Hom}({c''_2}^* L_2, {c''_3}^! L_3) & \xrightarrow{5.2.5} & \mathrm{Hom}(c_1^* L_1, c_3^! L_3) \\ \downarrow{\scriptstyle f_{12*} \otimes f_{23*}} & & \downarrow{\scriptstyle f_{13*}} \\ \mathrm{Hom}({d'_1}^* M_1, {d'_2}^! M_2) \otimes \mathrm{Hom}({d''_2}^* M_2, {d''_3}^! M_3) & \xrightarrow{5.2.5} & \mathrm{Hom}(d_1^* M_1, d_3^! M_3), \end{array} \tag{5.2.6}$$

where $M_1 = f_{1!} L_1$, $M_2 = f_{2*} L_2$, and $M_3 = f_{3*} L_3$.

Finally, suppose that $X_1 = X_3$ and $L_1 = L_3$. The fundamental pairing 4.1.2 may be interpreted as the composite of the pairing

$$q_1^* D L_1 \otimes^{\mathbf{L}} q_2^* L_2 \otimes^{\mathbf{L}} q_2^* D L_2 \otimes^{\mathbf{L}} q_1^* L_1 \longrightarrow q_1^* D L_1 \otimes^{\mathbf{L}} q_2^* K_{X_2} \otimes^{\mathbf{L}} q_1^* L_1 \tag{5.2.7}$$

defined by $L_2 \otimes^{\mathbf{L}} D L_2 \to K_{X_2}$, or, equivalently, induced by 5.2.1 on X_{12} via the diagonal $X_{12} \to X_1 \times_S X_2 \times_S X_1$ ($q_i : X_{12} \to X_i$ denoting the projection), and the pairing

$$q_1^* D L_1 \otimes^{\mathbf{L}} q_2^* K_{X_2} \otimes^{\mathbf{L}} q_1^* L_1 \longrightarrow K_{X_{12}} \tag{5.2.8}$$

defined by $D L_1 \otimes^{\mathbf{L}} L_1 \to K_{X_1}$. It follows that, for $u \in \mathrm{Hom}_S(L_1, L_2)$ and $v \in \mathrm{Hom}_S(L_2, L_1)$, one has, in $H^0(X_1 \times_S X_2, K_{X_1 \times_S X_2})$,

$$\langle u, v \rangle = \langle vu, 1 \rangle, \tag{5.2.9}$$

where 1 denotes the identity correspondence from L_1 to L_1 on $X_1 \times_S X_1$, supported on the diagonal (3.2 b)), and the cup product in the second member is taken in the sense of 4.2.5, taking account of the fact that the fibred product $X \times_{(X_1 \times_S X_1)} X_1$ (via $p_{13} : X \to X_{13} = X_1 \times_S X_1$ and the diagonal $X_1 \to X_1 \times_S X_1$) identifies with $X_1 \times_S X_2$. Likewise, more generally, if $c' : C' \to X_{12}$ and $c'' : C'' \to X_{21}$ are correspondences, if $c : C = C' \times_{X_2} C'' \to X_1 \times_S X_2 \times_S X_1$ is the composite correspondence, and if $d : C' \times_{X_{12}} C'' = D \to X_{12}$ is the intersection correspondence, then, for $u \in \mathrm{Hom}({c'_1}^* L_1, {c'_2}^! L_2)$ and $v \in \mathrm{Hom}({c''_2}^* L_2, {c''_1}^! L_1)$, one has the following equality in $H^0(D, K_D)$:

$$\langle u, v \rangle = \langle vu, 1 \rangle, \tag{5.2.10}$$

where 1 denotes, as above, the diagonal correspondence, and D is identified with the fibred product of $C \to X_1 \times_S X_1$ and the diagonal $X_1 \to X_1 \times_S X_1$. Formulas 5.2.9 and 5.2.10 generalize a well-known formula in the case of constant coefficients ([12] 1.3.6 (ii) c)).

5.3. External tensor product of correspondences

Let, for $1 \leq i \leq 4$, X_i be an S-scheme, let $X = X_1 \times_S X_2 \times_S X_3 \times_S X_4$, $X_{ij} = X_i \times_S X_j$, and let $L_i \in \operatorname{ob} D_{\mathrm{ctf}}(X_i)$. The Künneth isomorphism (1.7.6, 2.2.4)

$$DL_1 \otimes_S^{\mathbf{L}} DL_3 \xrightarrow{\sim} D(L_1 \otimes_S^{\mathbf{L}} L_3)$$

defines an isomorphism on X

$$(DL_1 \otimes_S^{\mathbf{L}} L_2) \otimes_S^{\mathbf{L}} (DL_3 \otimes_S^{\mathbf{L}} L_4) \xrightarrow{\sim} D(L_1 \otimes_S^{\mathbf{L}} L_3) \otimes_S^{\mathbf{L}} (L_2 \otimes_S^{\mathbf{L}} L_4), \tag{5.3.1}$$

which, by 3.1.1, may be rewritten in the form

$$\mathrm{RHom}_S(L_1, L_2) \otimes_S^{\mathbf{L}} \mathrm{RHom}_S(L_3, L_4) \xrightarrow{\sim} \mathrm{RHom}_S(L_1 \otimes_S^{\mathbf{L}} L_3, L_2 \otimes_S^{\mathbf{L}} L_4). \tag{5.3.2}$$

Hence a pairing, called the *external tensor product*,

$$\mathrm{Hom}_S(L_1, L_2) \otimes \mathrm{Hom}_S(L_3, L_4) \longrightarrow \mathrm{Hom}_S(L_1 \otimes_S^{\mathbf{L}} L_3, L_2 \otimes_S^{\mathbf{L}} L_4), \tag{5.3.3}$$

which will be denoted $(u, v) \mapsto u \otimes_S^{\mathbf{L}} v$. The pairing 5.3.2 may also be interpreted as the composite of the external tensor product

$$\mathrm{RHom}(E_1, E_2) \otimes_S^{\mathbf{L}} \mathrm{RHom}(E_3, E_4) \xrightarrow{\sim} \mathrm{RHom}(E_1 \otimes_S^{\mathbf{L}} E_3, E_2 \otimes_S^{\mathbf{L}} E_4)$$

(where $E_1 = p_{12,1}^* L_1$, etc., with the evident notation) and of the isomorphism defined by Künneth

$$E_2 \otimes_S^{\mathbf{L}} E_4 \xrightarrow{\sim} p_{24}^!(L_2 \otimes_S^{\mathbf{L}} L_4) \quad (1.7.3).$$

Let $c' : C' \to X_{12}$ and $c'' : C'' \to X_{34}$ be correspondences, and let $c : C = C' \times_S C'' \to X = X_{13} \times_S X_{24}$ be the product correspondence. From 5.3.2 one deduces, or else defines analogously, a pairing

$$\mathrm{RHom}({c'_1}^* L_1, {c'_2}^! L_2) \otimes_S^{\mathbf{L}} \mathrm{RHom}({c''_3}^* L_3, {c''_4}^! L_4) \longrightarrow \mathrm{RHom}(c_{13}^*(L_1 \otimes_S^{\mathbf{L}} L_3), c_{24}^!(L_2 \otimes_S^{\mathbf{L}} L_4)), \tag{5.3.4}$$

hence an external tensor product pairing, $(u, v) \mapsto u \otimes_S^{\mathbf{L}} v$,

$$\mathrm{Hom}({c'_1}^* L_1, {c'_2}^! L_2) \otimes \mathrm{Hom}({c''_3}^* L_3, {c''_4}^! L_4) \longrightarrow \mathrm{Hom}(c_{13}^*(L_1 \otimes_S^{\mathbf{L}} L_3), c_{24}^!(L_2 \otimes_S^{\mathbf{L}} L_4)). \tag{5.3.5}$$

One checks that these pairings are compatible with direct images, in the following sense. Let, for $1 \leq i \leq 4$, $f_i : X_i \to Y_i$ be an S-morphism, let c', c'', c be as above, with c' and c'' proper, let $d' : D' \to Y_{12}$ and $d'' : D'' \to Y_{34}$ be proper morphisms, let $d : D = D' \times_S D'' \to Y = Y_{12} \times_S Y_{34}$, and suppose given the commutative squares

$$\begin{array}{ccc} X_{12} & \longleftarrow & C' \\ {\scriptstyle f_{12}}\downarrow & & \downarrow \\ Y_{12} & \longleftarrow & D' \end{array} \qquad \begin{array}{ccc} X_{34} & \longleftarrow & C'' \\ {\scriptstyle f_{34}}\downarrow & & \downarrow \\ Y_{34} & \longleftarrow & D'' \end{array}$$

Then one has a commutative square

$$\begin{array}{ccc} \mathrm{Hom}({c'_1}^* L_1, {c'_2}^! L_2) \otimes \mathrm{Hom}({c''_3}^* L_3, {c''_4}^! L_4) & \xrightarrow{5.3.5} & \mathrm{Hom}(c_{13}^* L_{13}, c_{24}^! L_{24}) \\ \downarrow{\scriptstyle f_{12} \otimes f_{34}} & & \downarrow{\scriptstyle f_{13,24*}} \\ \mathrm{Hom}({d'_1}^* M_1, {d'_2}^! M_2) \otimes \mathrm{Hom}({d''_3}^* M_3, {d''_4}^! M_4) & \xrightarrow{5.3.5} & \mathrm{Hom}(d_{13}^* M_{13}, d_{24}^! M_{24}), \end{array} \tag{5.3.6}$$

where $M_i = f_{i!}L_i$ if $i = 1, 3$ and $f_{i*}L_i$ otherwise, $L_{ij} = L_i \otimes_S^{\mathbf{L}} L_j$, and $M_{ij} = M_i \otimes_S^{\mathbf{L}} M_j$ (there is also an analogous square with the RHom's).

Suppose that $X_3 = X_2$, $X_4 = X_1$, $L_3 = L_2$, and $L_4 = L_1$. A reasoning analogous to that of the last paragraph of 5.2 shows that, for $u \in \mathrm{Hom}_S(L_1, L_2)$ and $v \in \mathrm{Hom}_S(L_2, L_1)$, one has

$$\langle u, v\rangle = \langle u \otimes_S^{\mathbf{L}} v, 1\rangle, \tag{5.3.7}$$

where 1 denotes the diagonal correspondence from L_{12} to L_{12} on X_{12}, and the cup product in the second member is taken in the sense of 4.2.5. More generally, if $c' : C' \to X_{12}$ and $c'' : C'' \to X_{21}$ are correspondences, their "intersection" $C = C' \times_{X_{12}} C''$ identifies with the fibred product of $C' \times_S C'' \to X = X_{12} \times_S X_{21}$ and the diagonal $X_{12} \to X$, and, for $u \in \mathrm{Hom}(c_1'^* L_1, c_2'^! L_2)$ and $v \in \mathrm{Hom}(c_2''^* L_2, c_1''^! L_1)$, one has the following equality in $H^0(C, K_C)$:

$$\langle u, v\rangle = \langle u \otimes_S^{\mathbf{L}} v, 1\rangle, \tag{5.3.8}$$

where 1 denotes, as above, the diagonal correspondence. Thus there are two "diagonal" procedures (5.2.10, 5.3.8) for the calculation of the "Verdier local term" $\langle u, v\rangle$.

6. Appendix. Lefschetz formula for coherent sheaves

In this number, S denotes a noetherian scheme. The S-schemes considered will be assumed separated and of finite type. Recall that, by Nagata, every S-morphism between such schemes is compactifiable, i.e. factors as an open immersion followed by a proper morphism. For every S-scheme X, we shall write $D(X)$ for the derived category of the category of $\mathcal{O}_X$-modules.

6.1

Recall ([8] App.) that for every S-morphism $f : X \to Y$ one has a functor

$$f^! : D^+(Y) \longrightarrow D^+(X)$$

(and transitivity isomorphisms $(gf)^! = f^! g^!$ for a composite gf, with a cocycle condition). If f is proper, $f^!$ is right "adjoint" to the functor $f_* : D^+(X)_{\mathrm{coh}} \to D^+(Y)_{\mathrm{coh}}$ (where the subscript "coh" denotes the full subcategory formed by complexes with coherent cohomology), this adjunction being made precise by an isomorphism

$$f_* \mathrm{RHom}(E, f^! F) \xrightarrow{\sim} \mathrm{RHom}(f_* E, F) \tag{6.1.1}$$

for $E \in \mathrm{ob}\, D(X)_{\mathrm{coh}}$, $F \in \mathrm{ob}\, D^+(Y)$, defined analogously to the isomorphism (SGA 4 XVIII 3.1.9.6). The considerations of ([8] App.5), together with the duality theorem for projective space, show that, if f is smooth, purely of dimension d, there is a canonical isomorphism

$$f^! L \xleftarrow{\sim} f^* L \otimes \Omega^d_{X/Y}[d]; \tag{6.1.2}$$

and, if moreover f is proper, the arrow

$$\mathrm{Tr}_f : f_*(f^* L \otimes \Omega^d_{X/Y}[d]) \longrightarrow L \tag{6.1.3}$$

deduced, by 6.1.2, from the adjunction arrow $f_* f^! \to I$, coincides with the trace morphism ([8] VI).

6.2

Contrary to what happens in the case of discrete coefficients, there is no reasonable subcategory of D here that is stable under the "six operations" $(f^*, f_*, f^!, f_!, \otimes^{\mathbf{L}}, \mathrm{RHom})$. The most natural finiteness notion seems to be relative perfection (SGA 6 III 4). If X is an S-scheme and $L \in \mathrm{ob}\, D(X)$, recall that L is said to be perfect relative to S if L has finite tor-dimension relative to S and coherent cohomology. We shall denote by $D(X)_{\mathrm{parf}/S}$ the full subcategory of $D(X)$ formed by the complexes perfect relative to S. It is not stable in general either under $\otimes^{\mathbf{L}}$ or under RHom. However, if E is perfect in the absolute sense and F is perfect relative to S, then $\mathrm{RHom}(E, F)$ is perfect relative to S (SGA 6 III 4.9). On the other hand, let, for $i = 1, 2$, X_i be an S-scheme and $L_i \in \mathrm{ob}\, D^-(X_i)$. We shall put, as in 1.5,

$$L_1 \otimes^{\mathbf{L}}_S L_2 = Lp_1^* L_1 \otimes^{\mathbf{L}} Lp_2^* L_2,$$

where $p_i : X_1 \times_S X_2 \to X_i$ is the projection. Considering this object is reasonable only if X_1 and X_2 are tor-independent over S, i.e. (SGA 6 III 1.5) if $\mathrm{Tor}_i^S(\mathcal{O}_X, \mathcal{O}_Y) = 0$ for $i \neq 0$. Suppose this is the case: then, if L_1 and L_2 are perfect relative to S, so is $L_1 \otimes^{\mathbf{L}}_S L_2$ (SGA 6 III 4.7).

Let $f : X \to Y$ be an S-morphism. If f is proper, then $f_* D(X)_{\mathrm{parf}/S} \subset D(Y)_{\mathrm{parf}/S}$ (SGA 6 III 4.8). If f has finite tor-dimension, then $f^* D(Y)_{\mathrm{parf}/S} \subset D(X)_{\mathrm{parf}/S}$ (SGA 6 III 4.5), and $f^! D(Y)_{\mathrm{parf}/S} \subset D(X)_{\mathrm{parf}/S}$ (SGA 6 III 4.9).

For every S-scheme $a : X \to S$, we put

$$K_X = a^! \mathcal{O}_S, \tag{6.2.1}$$

and write D_X (or simply D) for the functor $\mathrm{RHom}(-, K_X)$. If X has finite tor-dimension over S, then K_X is perfect relative to S and, for every $L \in \mathrm{ob}\, D(X)_{\mathrm{parf}/S}$, one has $DL \in \mathrm{ob}\, D(X)_{\mathrm{parf}/S}$, and the canonical arrow $L \to DDL$ is an isomorphism (SGA 6 III 4.9).

Let $f : X \to Y$ be an S-morphism, $L \in \mathrm{ob}\, D(X)$, and $M \in \mathrm{ob}\, D(Y)$. If $f^* M$ is defined (for example if $M \in \mathrm{ob}\, D^-(Y)$, or if f has finite tor-dimension), put

$$\mathrm{Hom}_f^{(1)}(L, M) = \mathrm{Hom}(f^* M, L), \qquad \mathrm{Hom}_f^{(2)}(L, M) = \mathrm{Hom}(L, f^* M).$$

If $f^! M$ is defined (for example if $M \in \mathrm{ob}\, D^+(Y)$, or if f is smooth, or finite of finite tor-dimension, or a composite of such morphisms, since in these cases $f^!$ extends, by 6.1.1 and 6.1.2, to a functor defined on the whole category $D(Y)$), put

$$\mathrm{Hom}_f^{(3)}(L, M) = \mathrm{Hom}(L, f^! M), \qquad \mathrm{Hom}_f^{(4)}(L, M) = \mathrm{Hom}(f^! M, L).$$

The elements of $\mathrm{Hom}_f^{(i)}(L, M)$ will be called, as in 1.4, *arrows of type i from L to M over f* (or f-arrows of type i from L to M). We leave to the reader the task of making explicit the composition of arrows of type i, for fixed i, and the corresponding fibred and cofibred categories. We recall only the partial adjunction formulas

$$\mathrm{Hom}_f^{(1)}(L, M) = \mathrm{Hom}(M, f_* L) \quad (M \in \mathrm{ob}\, D^-(Y),\ L \in \mathrm{ob}\, D^+(X)),$$

$$\mathrm{Hom}_f^{(3)}(L, M) = \mathrm{Hom}(f_* L, M) \quad (f \text{ proper},\ L \in \mathrm{ob}\, D(X)_{\mathrm{coh}},\ M \in \mathrm{ob}\, D^+(Y)).$$

6.3

In the situation of 1.6, suppose that X_1 and X_2 are tor-independent over S, and likewise Y_1 and Y_2. Then, for $L_i \in \mathrm{ob}\, D(X_i)_{\mathrm{parf}/S}$, the Künneth arrow 1.6.4 is defined (use the fact that finite relative tor-dimension is preserved by direct image (SGA 6 III 3.7.1)) and is an isomorphism (to verify this, one may assume S and the Y_i affine, and, for a Čech calculation, reduce to also assuming X_1 and X_2 affine; the conclusion is then a trivial consequence of the tor-independence hypotheses). On the other hand, for $M_i \in \mathrm{ob}\, D(Y_i)_{\mathrm{parf}/S}$, with $f_1^! M_1$ or $f_2^! M_2$ in D^b, the Künneth arrow 1.7.3 is defined[12], and is an isomorphism when f_1 and f_2 have finite tor-dimension, as is easily checked with the help of the Künneth isomorphism of type 1.6.4 just indicated, conjugated with 6.1.2, and with 6.1.1 in the case where f_i is a closed immersion. In particular, if X_1 and X_2 have finite tor-dimension over S and are tor-independent, 1.7.6 is an isomorphism.

One defines $\mathrm{RHom}(u, v)$ as in 2.1 for (u, v) of type $(2, 1)$ (respectively $(3, 4)$, with f proper in order to avoid the pro-objects caused by an $f_!$). Under suitable degree hypotheses (see for example ([9] V 2.3)), the evaluation arrows (2.2.2) and tensor-product arrows (2.2.3, 2.2.4) are defined, and the arrows 2.2.3 and 2.2.4 (provided they are defined) are isomorphisms as soon as E_1 and E_2 are perfect in the absolute sense.

In the situation of 2.4, suppose that the pairs (X_1, X_2), (X_1, Y_2), (Y_1, X_2), (Y_1, Y_2) are tor-independent over S, that f_1 is proper, that E_i, F_i, P_i, Q_i, $\mathrm{RHom}(E_i, F_i)$, $\mathrm{RHom}(P_i, Q_i)$ are perfect relative to S, and that the Künneth arrows

$$f_1^! Q_1 \otimes_S^{\mathbf{L}} Q_2 \to (f_1 \times_S Y_2)^!(Q_1 \otimes_S^{\mathbf{L}} Q_2), \qquad f_1^! Q_1 \otimes_S^{\mathbf{L}} F_2 \to (f_1 \times_S Y_2)^!(Q_1 \otimes_S^{\mathbf{L}} F_2)$$

are isomorphisms. Then 2.4.1 and the diagram of 2.5 are defined, and the latter is commutative (however, the horizontal arrows are not necessarily isomorphisms). The verification is the same as for 2.5.

6.4

Let, for $i = 1, 2$, X_i be an S-scheme, let $X = X_1 \times_S X_2$, and let $p_i : X \to X_i$, $q_i : X_i \to S$ be the canonical projections. Suppose that X_1 and X_2 are tor-independent and that q_1 has finite tor-dimension. Let $L_i \in \mathrm{ob}\, D(X_i)_{\mathrm{parf}/S}$. By the analogue of 2.2.4, one has a canonical arrow

$$DL_1 \otimes_S^{\mathbf{L}} L_2 \longrightarrow \mathrm{RHom}(L_1 \otimes_S^{\mathbf{L}} \mathcal{O}_{X_2}, q_1^! \mathcal{O}_S \otimes_S^{\mathbf{L}} L_2), \tag{6.4.1}$$

and hence, by composing with the Künneth isomorphism (6.3) $q_1^! \mathcal{O}_S \otimes_S^{\mathbf{L}} L_2 \xrightarrow{\sim} p_2^! L_2$, an arrow

$$DL_1 \otimes_S^{\mathbf{L}} L_2 \longrightarrow \mathrm{RHom}(p_1^* L_1, p_2^! L_2). \tag{6.4.2}$$

The arrow 6.4.1, and therefore also 6.4.2, is an isomorphism, as one sees by reducing to the case where q_1 is a closed immersion.

As in 3.1.2, we shall put

$$\mathrm{RHom}(p_1^* L_1, p_2^! L_2) = \mathrm{RHom}_S(L_1, L_2), \qquad \mathrm{Hom}(p_1^* L_1, p_2^! L_2) = \mathrm{Hom}_S(L_1, L_2), \tag{6.4.3}$$

[12] In the proper or lissifiable case, the definition of the arrow is immediate; the general case can be reduced to the lissifiable case by cohomological descent.

and call the elements of $\mathrm{Hom}_S(L_1, L_2)$ *cohomological correspondences from* L_1 *to* L_2. If $c : C \to X$ is a correspondence (proper in practice), then by the induction formula ([8] III 8.8)[13]

$$c^!\mathrm{RHom}(p_1^*L_1, p_2^!L_2) = \mathrm{RHom}(c_1^*L_1, c_2^!L_2), \tag{6.4.4}$$

and the elements of

$$\mathrm{Hom}(c_1^*L_1, c_2^!L_2) = H^0(X, c_*c^!\mathrm{RHom}(p_1^*L_1, p_2^!L_2))$$

will be called *cohomological correspondences from* L_1 *to* L_2 *with support in* C. We shall see below examples analogous to those of 3.2.

6.5

Let, for $i = 1, 2$, $f_i : X_i \to Y_i$ be a proper S-morphism, and let $f = f_1 \times_S f_2 : X \to Y$. Suppose that the X_i and Y_i have finite tor-dimension over S, and that the squares of 2.4.0 are tor-independent. Let $L_i \in \mathrm{ob}\, D(X_i)_{\mathrm{parf}/S}$. As in 3.3.1, one defines an isomorphism

$$f_*\mathrm{RHom}_S(L_1, L_2) \xrightarrow{\sim} \mathrm{RHom}_S(f_{1*}L_1, f_{2*}L_2), \tag{6.5.1}$$

hence, by applying $R\Gamma(Y, -)$, an isomorphism

$$f_* : \mathrm{Hom}_S(L_1, L_2) \xrightarrow{\sim} \mathrm{Hom}_S(f_{1*}L_1, f_{2*}L_2), \tag{6.5.2}$$

which we shall simply denote by $u \mapsto u_*$ when $Y_1 = Y_2 = S$. There is a commutative diagram analogous to 3.4.1, as follows from the analogue of 2.5 indicated in 6.3. One deduces from it a corollary analogous to 6.5 and, in the case where $Y_1 = Y_2 = S$ is the spectrum of a field, a description, analogous to that of 3.6, of the operations u_* on cohomology.

Given a commutative square 3.7.1, with c proper, one has, for $K \in \mathrm{ob}\, D^+(C)$, a canonical arrow

$$f_*c_*c^!K \longrightarrow d_*d^!f_*K, \tag{6.5.3}$$

defined in the same way as 3.7.3 (the isomorphism $g'_*c'^! \xrightarrow{\sim} d^!f_*$ is also valid in the present context: definition of the arrow by transposition of a base-change arrow, and verification that it is an isomorphism by reduction to the cases where d is smooth and where d is a closed immersion). Taking $K = \mathrm{RHom}_S(L_1, L_2)$, one deduces from 6.5.3 and 6.5.1 canonical arrows

$$f_*c_*\mathrm{RHom}(c_1^*L_1, c_2^!L_2) \longrightarrow d_*\mathrm{RHom}(d_1^*(f_{1*}L_1), d_2^!(f_{2*}L_2)), \tag{6.5.4}$$

$$f_* : \mathrm{Hom}(c_1^*L_1, c_2^!L_2) \longrightarrow \mathrm{Hom}(d_1^*(f_{1*}L_1), d_2^!(f_{2*}L_2)), \tag{6.5.5}$$

analogous to 3.7.5 and 3.7.6.

6.6

Let, for $i = 1, 2$, X_i be S-schemes of finite tor-dimension and tor-independent over S, and let $L_i \in \mathrm{ob}\, D(X_i)_{\mathrm{parf}/S}$. The external tensor product of the evaluation arrows $DL_i \otimes^{\mathbf{L}} L_i \to K_{X_i}$ defines, as in 4.1, "cup-product" pairings analogous to 4.1.2, 4.1.3, and 4.1.4.

[13] The "lissifiability" hypothesis of (loc. cit.) is unnecessary.

Let $c : C \to X$ and $d : D \to X$ be proper morphisms, let $e = c \times_X d : E \to X$, and let $P, Q \in \operatorname{ob} D(X)_{\mathrm{parf}/S}$. By 6.1.1, one has

$$c_* c^! P = \mathrm{RHom}(Rc_* \mathcal{O}_C, P)$$

(and an analogous isomorphism with d). Assuming c and d of finite tor-dimension at the points above $e(E)$, one deduces, by tensor product, a canonical arrow

$$c_* c^! P \otimes^{\mathbf{L}} d_* d^! Q \longrightarrow \mathrm{RHom}(Rc_* \mathcal{O}_C \otimes^{\mathbf{L}} Rd_* \mathcal{O}_D, P \otimes^{\mathbf{L}} Q). \tag{6.6.1}$$

When c and d are tor-independent, the second member is rewritten, by Künneth and 6.1.1, as $e_* e^!(P \otimes^{\mathbf{L}} Q)$, and 6.6.1 takes the form 4.2.3. For $P = DL_1 \otimes^{\mathbf{L}}_S L_2$, $Q = L_1 \otimes^{\mathbf{L}}_S DL_2$, one deduces from 6.6.1 and the pairings indicated above pairings analogous to 4.2.4 and 4.2.5:

$$c_* \mathrm{RHom}(c_1^* L_1, c_2^! L_2) \otimes^{\mathbf{L}} d_* \mathrm{RHom}(d_2^* L_2, d_1^! L_1) \longrightarrow \mathrm{RHom}(Rc_* \mathcal{O}_C \otimes^{\mathbf{L}} Rd_* \mathcal{O}_D, K_X), \tag{6.6.2}$$

$$\langle\ ,\ \rangle : \mathrm{Hom}(c_1^* L_1, c_2^! L_2) \otimes \mathrm{Hom}(d_2^* L_2, d_1^! L_1) \longrightarrow \mathrm{Hom}(Rc_* \mathcal{O}_C \otimes^{\mathbf{L}} Rd_* \mathcal{O}_D, K_X). \tag{6.6.3}$$

Just like the pairings of 4.2, these are compatible with étale localization. When c and d are tor-independent, the second member of 6.6.2 (respectively 6.6.3) identifies canonically with $e_* K_E$ (respectively $H^0(E, K_E)$).

Theorem 4.4 has the following analogue:

Theorem 6.7. Let, for $i = 1, 2$, $f_i : X_i \to Y_i$ be a proper S-morphism, let $f = f_1 \times_S f_2 : X \to Y$, and let $p_i : X \to X_i$, $q_i : Y \to Y_i$ be the projections. Suppose given, on the other hand, a cube 4.4.0 with cartesian horizontal faces, with c', c'', d', d'' proper, and with c', c'' (respectively d', d'') of finite tor-dimension at the points above $c(C)$ (respectively $d(D)$). Put $c'_i = p_i c'$, $c''_i = p_i c''$, $d'_i = q_i d'$, and $d''_i = q_i d''$. Finally, let $L_i \in \operatorname{ob} D(X_i)_{\mathrm{parf}/S}$. Assume that the pairs (X_1, X_2), (X_1, Y_2), (Y_1, X_2), (Y_1, Y_2) are tor-independent over S, and that X_i and Y_i have finite tor-dimension over S. Then one has a commutative square

$$\begin{array}{ccc} f_* c'_* \mathrm{RHom}(c_1'^* L_1, c_2'^! L_2) \otimes^{\mathbf{L}} f_* c''_* \mathrm{RHom}(c_2''^* L_2, c_1''^! L_1) & \xrightarrow{(1)} & f_* \mathrm{RHom}(Rc'_* \mathcal{O}_{C'} \otimes^{\mathbf{L}} Rc''_* \mathcal{O}_{C''}, K_X) \\ \downarrow{\scriptstyle (2)} & & \downarrow{\scriptstyle (4)} \\ d'_* \mathrm{RHom}(d_1'^* M_1, d_2'^! M_2) \otimes^{\mathbf{L}} d''_* \mathrm{RHom}(d_2''^* M_2, d_1''^! M_1) & \xrightarrow{(3)} & \mathrm{RHom}(Rd'_* \mathcal{O}_{D'} \otimes^{\mathbf{L}} Rd''_* \mathcal{O}_{D''}, K_Y), \end{array} \tag{6.7.1}$$

where $M_i = f_{i*} L_i$, (3) is given by 6.6.2, (1) is deduced from 6.6.2 by application of f_* and composition with the canonical arrow $f_* c'_* \otimes^{\mathbf{L}} f_* c''_* \to f_*(c'_* \otimes^{\mathbf{L}} c''_*)$, (2) is the tensor product of the arrows 6.5.4 relative to the faces containing f, and (4) is the composite of the duality isomorphism 6.1.1 and of the arrow defined by the canonical arrow

$$Rd'_* \mathcal{O}_{D'} \otimes^{\mathbf{L}} Rd''_* \mathcal{O}_{D''} \longrightarrow f_*(Rc'_* \mathcal{O}_{C'} \otimes^{\mathbf{L}} Rc''_* \mathcal{O}_{C''})$$

which is adjoint to the tensor product of the base-change arrows $f^* Rd'_* \mathcal{O}_{D'} \to Rc'_* \mathcal{O}_{C'}$, $f^* Rd''_* \mathcal{O}_{D''} \to Rc''_* \mathcal{O}_{C''}$.

The proof is essentially the same as that of 4.4; we leave to the reader the small modifications to be made.

When c' and c'' are tor-independent, and likewise d' and d'', the arrow (4) of 6.7.1 is rewritten in the form $f_*c_*K_C \to d_*K_D$; it is simply defined by the adjunction arrow $g_*K_C = g_*g^!K_D \to K_D$ (as is arrow (4) of 4.4.1). However, it would not be natural to consider only this case, since that would exclude correspondences with excess intersection.

From 6.7 one deduces formulas analogous to 4.5.1 and 4.7.1: under the hypotheses of 6.7, one has, for $u \in \mathrm{Hom}({c'_1}^*L_1, {c'_2}^!L_2)$ and $v \in \mathrm{Hom}({c''_2}^*L_2, {c''_1}^!L_1)$,

$$\langle f_*u, f_*v\rangle = f_*\langle u, v\rangle, \tag{6.7.2}$$

where f_*u (respectively f_*v) denotes the direct image correspondence of u (respectively v) in the sense of 6.5.5, and f_* in the second member is the homomorphism

$$\mathrm{Hom}(Rc'_*\mathcal{O}_{C'} \otimes^{\mathbf{L}} Rc''_*\mathcal{O}_{C''}, K_X) \longrightarrow \mathrm{Hom}(Rd'_*\mathcal{O}_{D'} \otimes^{\mathbf{L}} Rd''_*\mathcal{O}_{D''}, K_Y) \tag{6.7.3}$$

which is the composite of the duality isomorphism 6.1.1 and the arrow induced by the canonical arrow

$$Rd'_*\mathcal{O}_{D'} \otimes^{\mathbf{L}} Rd''_*\mathcal{O}_{D''} \longrightarrow f_*(Rc'_*\mathcal{O}_{C'} \otimes^{\mathbf{L}} Rc''_*\mathcal{O}_{C''})$$

cited in 6.7. When $Y_1 = Y_2 = S = D' = D''$, 6.7.2 is the *Lefschetz-Verdier formula.*

As an illustration, we shall show that this formula implies the Woods Hole formula [1].

6.8

For this purpose we shall need a few reminders on the "Hodge" cohomology class associated with a regularly embedded subscheme of a smooth scheme and on Grothendieck residues ([8] III 9). Let $f : X \to S$ be a smooth morphism purely of relative dimension N, and let $i : Y \hookrightarrow X$ be a regular immersion of codimension d, i.e. ((SGA IV 16.9.2), (SGA 6 VII 1)) a closed subscheme defined locally by a regular sequence of d equations, or, in equivalent terminology ((8 III 1), (SGA 6 VIII 1)), a closed immersion, locally a complete intersection, of codimension d. Put $g = fi$. Then one associates with Y an element

$$\mathrm{cl}^d_{X/S}(Y) \in \mathrm{Ext}^d_{\mathcal{O}_X}(\mathcal{O}_Y, \Omega^d_{X/S}), \tag{6.8.1}$$

called the *cohomology class associated with* Y, defined as follows. By the "purity" theorem ([8] III 7.2), one has

$$\mathrm{Ext}^i_{\mathcal{O}_X}(\mathcal{O}_Y, \Omega^d_{X/S}) = \begin{cases} 0, & i \neq d, \\ \mathrm{Hom}(\bigwedge^d N_{Y/X}, \Omega^d_{X/S} \otimes \mathcal{O}_Y), & i = d, \end{cases} \tag{6.8.2}$$

where $N_{Y/X} = I/I^2$ is the conormal sheaf ($I = \mathrm{Ker}\ \mathcal{O}_X \to \mathcal{O}_Y$). Therefore

$$\mathrm{Ext}^d_{\mathcal{O}_X}(\mathcal{O}_Y, \Omega^d_{X/S}) = H^0(Y, \underline{\mathrm{Hom}}(\bigwedge^d N_{Y/X}, \Omega^d_{X/S} \otimes \mathcal{O}_Y)). \tag{6.8.3}$$

The differential $d_{X/S} : \mathcal{O}_X \to \Omega^1_{X/S}$ induces an $\mathcal{O}_Y$-linear map

$$d_{X/S} \otimes 1 : N_{Y/X} \longrightarrow \Omega^1_{X/S} \otimes \mathcal{O}_Y.$$

The d-th exterior power of this map is a global section, on Y, of $\Lambda^d N^\vee_{Y/X} \otimes \Omega^d_{X/S}$; its image in $\mathrm{Ext}^d_{\mathcal{O}_X}(\mathcal{O}_Y, \Omega^d_{X/S})$ under the isomorphism 6.8.3 is, by definition, the class 6.8.1.

Assume g finite and flat (hence $d = N$). Let $\omega \in H^0(Y, \Lambda^d N_{Y/X}^\vee \otimes \Omega^d_{X/S})$. By 6.8.2 and 6.1, one may view ω as a homomorphism

$$\mathcal{O}_Y \longrightarrow g^!\mathcal{O}_S (= \Lambda^d N_{Y/X}^\vee \otimes \Omega^d_{X/S}),$$

and therefore, by adjunction, as a homomorphism $g_*\mathcal{O}_Y \to \mathcal{O}_S$. The residue (relative to g) of ω is defined as the section of $\mathcal{O}_S$ which is the image of 1 under this homomorphism, and is denoted $\mathrm{Res}_{Y/S}(\omega)$ (cf. ([8] III 9)). Let, on the other hand, $i_*\omega \in H^N(X, \Omega^N_{X/S})$ denote the image of ω by the composite of the isomorphism 6.8.3 and the canonical arrow

$$\mathrm{Ext}^N_{\mathcal{O}_X}(\mathcal{O}_Y, \Omega^N_{X/S}) \longrightarrow H^N(X, \Omega^N_{X/S}).$$

When f is proper, it follows from transitivity for trace morphisms (or adjunction arrows) $i_*i^! \to 1$, $f_*f^! \to 1$, that

$$\mathrm{Res}_{Y/S}(\omega) = \mathrm{Tr}_f(i_*\omega), \tag{6.8.4}$$

where $\mathrm{Tr}_f : H^N(X, \Omega^N_{X/S}) \to H^0(S, \mathcal{O}_S)$ is defined by the adjunction arrow $f_*f^!\mathcal{O}_S = Rf_*\Omega^N_{X/S}[N] \to \mathcal{O}_S$ (6.1). On the other hand, without any properness hypothesis, one has the important compatibility ([8] III 9 R6)

$$\mathrm{Res}_{Y/S}(y\, \mathrm{cl}_{X/S}(Y)) = \mathrm{Tr}_{Y/S}(y), \tag{6.8.5}$$

for $y \in H^0(Y, \mathcal{O}_Y)$, where $\mathrm{Tr}_{Y/S} : g_*\mathcal{O}_Y \to \mathcal{O}_S$ denotes the trace in the classical sense, i.e. $\mathrm{Tr}_{Y/S}(y)$ is the trace of the endomorphism of $g_*\mathcal{O}_Y$ defined by multiplication by y (this compatibility is not proved in loc. cit.; the case $N = 1$ is treated in [Raynaud, Anneaux locaux henséliens, VII 1, Lecture Notes in Math. n° 169, Springer Verlag, 1970]). In other words, $\mathrm{Tr}_{Y/S}$ corresponds, by adjunction, to the homomorphism $\mathcal{O}_Y \to g^!\mathcal{O}_S$ defined by multiplication by $\mathrm{cl}_{X/S}(Y)$. It follows that, for $F \in \mathrm{ob}\, D(S)_{\mathrm{coh}}$, the arrow

$$g^*F \longrightarrow g^!F = g^*F \otimes^{\mathbf{L}} g^!\mathcal{O}_S \tag{6.8.6}$$

given by multiplication by $\mathrm{cl}_{X/S}(Y)$ corresponds by adjunction to the arrow

$$g_*g^*F = F \otimes^{\mathbf{L}} g_*\mathcal{O}_Y \longrightarrow F \tag{6.8.7}$$

defined by $\mathrm{Tr}_{Y/S} : g_*\mathcal{O}_Y \to \mathcal{O}_S$.

6.9

Let X (respectively Y) be a proper smooth S-scheme of relative dimension m (respectively n), $Z = X \times_S Y$, and let $a : A \hookrightarrow Z$, $b : B \hookrightarrow Z$ be regular immersions such that $a_2 : A \to Y$, $b_1 : B \to X$ are finite and flat (write $p_1 : Z \to X$, $p_2 : Z \to Y$ for the projections, and $a_i = p_i a$, $b_i = p_i b$). Let $c : C = A \times_Z B \to Z$, $L \in \mathrm{ob}\, D(X)_{\mathrm{parf}}$, $M \in \mathrm{ob}\, D(Y)_{\mathrm{parf}}$ (the subscript parf means "perfect in the absolute sense", which is also equivalent to being perfect rel. to S, since X and Y are smooth). Assume that C is finite and flat over S. The hypotheses made therefore imply that c is a regular immersion and that a and b are tor-independent.

One has $p_1^*\Omega^1_{X/S} = \Omega^1_{Z/Y}$, $p_2^*\Omega^1_{Y/S} = \Omega^1_{Z/X}$, and a decomposition

$$\Omega^1_{Z/S} = \Omega^1_{Z/Y} \oplus \Omega^1_{Z/X},$$

whence, for every integer r, a decomposition

$$\Omega^r_{Z/S} = \bigoplus_{i+j=r} \Omega^i_{Z/Y} \otimes \Omega^j_{Z/X}. \tag{6.9.0}$$

On the other hand, by 6.1.2, one has $p_2^! M = p_2^* M \otimes \Omega^m_{Z/Y}[m]$, hence

$$H^0(Z, a_* a^! \mathrm{RHom}(p_1^* L, p_2^! M)) = \mathrm{Ext}^m_{\mathcal{O}_Z}(a_1^* L, a_2^* M \otimes \Omega^m_{Z/Y}),$$

whence, by 6.4.4 and 6.8.2, an isomorphism

$$\mathrm{Hom}(a_1^* L, a_2^! M) = H^0(A, \mathrm{RHom}(a_1^* L, a_2^* M) \otimes \Lambda^m N^\vee_{A/Z} \otimes \Omega^m_{Z/Y}). \tag{6.9.1}$$

Similarly one has an isomorphism

$$\mathrm{Hom}(b_2^* M, b_1^! L) = H^0(B, \mathrm{RHom}(b_2^* M, b_1^* L) \otimes \Lambda^n N^\vee_{B/Z} \otimes \Omega^n_{Z/X}). \tag{6.9.2}$$

Let $u \in \mathrm{Hom}(a_1^* L, a_2^* M)$, $v \in \mathrm{Hom}(b_2^* M, b_1^* L)$, and write

$$\langle u, v \rangle \in H^0(C, \mathcal{O}_C) \tag{6.9.3}$$

for the section $\mathrm{Tr}(u_C v_C) = \mathrm{Tr}(v_C u_C)$, where $u_C \in \mathrm{Hom}(c_1^* L, c_2^* M)$ and $v_C \in \mathrm{Hom}(c_2^* M, c_1^* L)$ are induced by u and v. Consider the cohomological correspondence $u^! \in \mathrm{Hom}(a_1^* L, a_2^! M)$ (respectively $v^! \in \mathrm{Hom}(b_2^* M, b_1^! L)$) deduced from u (respectively v) by composition with the trace homomorphism 6.8.7 $a_{2*} a_2^* M \to M$ (respectively $b_{1*} b_1^* L \to L$), or equivalently (6.8.6) by product with $\mathrm{cl}_{Z/Y}(A)$ (respectively $\mathrm{cl}_{Z/X}(B)$). Note in passing that $\mathrm{cl}_{Z/Y}(A)$ (respectively $\mathrm{cl}_{Z/X}(B)$) is the component in $H^0(A, \Lambda^m N^\vee_{A/Z} \otimes \Omega^m_{Z/Y})$ (respectively $H^0(B, \Lambda^n N^\vee_{B/Z} \otimes \Omega^n_{Z/X})$) of $\mathrm{cl}_{Z/S}(A)$ (respectively $\mathrm{cl}_{Z/S}(B)$) defined by the projection $\Omega^m_{Z/S} \to \Omega^m_{Z/Y}$ (respectively $\Omega^n_{Z/S} \to \Omega^n_{Z/X}$) of 6.9.0. One checks easily that the cup-product

$$\langle u^!, v^! \rangle \in \mathrm{Ext}^{m+n}_{\mathcal{O}_Z}(\mathcal{O}_C, \Omega^{m+n}_{Z/S}) = H^0(C, \Lambda^{m+n} N^\vee_{C/Z} \otimes \Omega^{m+n}_{Z/S})$$

defined in 6.6.3 is given by

$$\langle u^!, v^! \rangle = \langle u, v \rangle \, \mathrm{cl}_{Z/Y}(A) \, \mathrm{cl}_{Z/X}(B). \tag{6.9.4}$$

On the other hand one checks that the homomorphism 6.7.3

$$\mathrm{Ext}^{m+n}_{\mathcal{O}_Z}(\mathcal{O}_C, \Omega^{m+n}_{Z/S}) \longrightarrow H^0(S, \mathcal{O}_S)$$

is the composite of the canonical arrow $\mathrm{Ext}^{m+n}_{\mathcal{O}_Z}(\mathcal{O}_C, \Omega^{m+n}_{Z/S}) \to H^{m+n}(Z, \Omega^{m+n}_{Z/S})$ and the trace morphism $\mathrm{Tr}_{Z/S} : H^{m+n}(Z, \Omega^{m+n}_{Z/S}) \to H^0(S, \mathcal{O}_S)$. The Lefschetz-Verdier formula 6.7.2 therefore gives the relation

$$\langle (u^!)_*, (v^!)_* \rangle = \mathrm{Tr}_{Z/S}(\langle u, v \rangle \, \mathrm{cl}_{Z/Y}(A) \, \mathrm{cl}_{Z/X}(B)). \tag{6.9.5}$$

Thanks to 6.8.4 one may rewrite the second member as a residue; thus, in summary, one has obtained:

Theorem 6.10. Under the hypotheses of the first paragraph of 6.9, let $u \in \mathrm{Hom}(a_1^* L, a_2^* M)$, $v \in \mathrm{Hom}(b_2^* M, b_1^* L)$, and consider the cohomological correspondence $u^!$ (respectively $v^!$) from L to M (respectively from M to L), with support in A (respectively B), deduced from u (respectively v) by composition with the trace $a_{2*} a_2^* M \to M$ (respectively $b_{1*} b_1^* L \to L$) (6.8.7), and the homomorphism $(u^!)_* : f_* L \to g_* M$ (respectively $(v^!)_* : g_* M \to f_* L$) deduced from $u^!$ (respectively $v^!$) by direct

image (6.5.5) ($f : X \to S$, $g : Y \to S$ denoting the projections). Then, with the notation of 6.8, 6.9.3, one has

$$\langle (u^!)_*, (v^!)_* \rangle = \mathrm{Res}_{C/S}(\langle u, v \rangle \, \mathrm{cl}_{Z/Y}(A) \, \mathrm{cl}_{Z/X}(B)). \tag{6.10.1}$$

Remarks 6.11. a) As in 3.6, using the description 3.5 b) of the direct image of a correspondence, one checks that, if $h : Z \to S$ is the projection, $(u^!)_*$ (respectively $(v^!)_*$) is the composite of the arrows

$$f_*L \xrightarrow{(1)} (ha)_* a_1^* L \xrightarrow{(ha)_* u} (ha)_* a_2^* M = g_* a_{2*} a_2^* M \xrightarrow{(2)} g_* M,$$

$$(\text{respectively } g_*M \xrightarrow{(1)} (hb)_* b_2^* M \xrightarrow{(hb)_* v} (hb)_* b_1^* L = f_* b_{1*} b_1^* L \xrightarrow{(2)} f_* L),$$

where (1) is the usual functoriality arrow (defined by the adjunction arrow $1 \to a_{1*}a_1^*$ (respectively $1 \to b_{2*}b_2^*$)) and (2) is given by the trace $a_{2*}a_2^*M \to M$ (respectively $b_{1*}b_1^*L \to L$) (6.8.7).

b) Suppose that S is the spectrum of a field. The intersection $C = A \times_{(X \times_S Y)} B$ is then formed of isolated points. At each point z of C, choose, near the images of z, regular sequences $(s_1, \ldots, s_m)$, $(t_1, \ldots, t_n)$ of equations of A, B. Then 6.10.1 is written, with the notation of the residue symbols of ([8] III 9), as

$$\langle (u^!)_*, (v^!)_* \rangle = \sum_{z \in C} \mathrm{Res}_z \left(\langle u, v \rangle \prod_{1 \le i \le m} \frac{d_{Z/Y} s_i}{s_i} \prod_{1 \le j \le n} \frac{d_{Z/X} t_j}{t_j} \right), \tag{6.11.1}$$

where $d_{Z/Y}s_i$ (respectively $d_{Z/X}t_j$) denotes the component of type $(1,0)$ (respectively $(0,1)$) of $d_{Z/S}s_i$ (respectively $d_{Z/S}t_j$) in the decomposition 6.9.0.

Corollary 6.12. (Woods-Hole formula [1]). Assume that S is the spectrum of a field. Let X be a proper smooth S-scheme, F an S-endomorphism of X, L an object of $D(X)_{\mathrm{parf}}$ (i.e. a perfect complex on X), and $u \in \mathrm{Hom}(F^*L, L)$. Assume that the scheme of fixed points X^F is finite and consists of transverse points (i.e. points where the graph of F meets the diagonal transversely). Then

$$\sum_i (-1)^i \, \mathrm{Tr}((F,u), H^i(X,L)) = \sum_{x \in X^F} \frac{\mathrm{Tr}(u_x)}{\det(1 - dF_x)},$$

where (F,u) is the endomorphism of $H^i(X,L)$ which is the composite of $H^i(X,L) \to H^i(X, F^*L)$ (inverse image) and $H^i(X,u)$, $\mathrm{Tr}(u_x)$ denotes the value at x of the endomorphism induced by u on the fibre of L at x, and $\det(1 - dF_x)$ is the value at x of the determinant of the map (1 − map induced by F on $\Omega^1_{X,x}$).

Proof. Apply 6.10, taking account of 6.11 a), b). Put $Z = X \times_S X$. Let $x \in X^F$. Near x, choose a system of local coordinates $(x_1, \ldots, x_n)$ (defining an étale morphism into $\mathbb{A}^n_S$), put $F_i = x_i F$, and write $(x_1, \ldots, x_n, y_1, \ldots, y_n)$ for the corresponding local coordinates on Z near $z = (x,x)$ ($x_i = x_i \otimes 1$, $y_i = 1 \otimes x_i$). Then, near z, $(x_1 - y_1, \ldots, x_n - y_n)$ (respectively $(y_1 - F_1, \ldots, y_n - F_n)$) is a regular system of equations for the diagonal A (respectively for the graph B of F). The contribution at z of the second member of 6.11.1 is

$$\langle u, 1 \rangle_z = \mathrm{Res}_z \left(\mathrm{Tr}(u) \frac{dx_1 \cdots dx_n \, dy_1 \cdots dy_n}{(x_1 - y_1) \cdots (x_n - y_n)(y_1 - F_1) \cdots (y_n - F_n)} \right).$$

Observe that in the numerator one may replace dy_i by

$$dy_i - dF_i = dy_i - \sum_{1 \le j \le n} (dF_i / dx_j) dx_j.$$

Applying then formula ([8] III 9 R3) to the situation $(B \hookrightarrow Z \to S)$, $(s_1, \dots, s_p) = (y_1 - F_1, \dots, y_n - F_n)$, $(t_1, \dots, t_n) = (x_1 - y_1, \dots, x_n - y_n)$, $\omega = (\mathrm{Tr}(u) dx_1 \cdots dx_n)$, one obtains

$$\langle u, 1 \rangle_z = \mathrm{Res}_x \left(\mathrm{Tr}(u) \frac{dx_1 \cdots dx_n}{(x_1 - F_1) \cdots (x_n - F_n)} \right). \tag{*}$$

Since x is transverse, the $x_i - F_i$ form a regular system of parameters of $\mathcal{O}_{X,x}$, and hence one may write, near x,

$$x_i = \sum_j (x_j - F_j) c_{ij},$$

where (c_{ij}) is a matrix of sections of $\mathcal{O}_X$ invertible at x, whose determinant has value at x equal to $\det(1 - dF_x)^{-1}$. Thanks to ([8] III 9 R1), one therefore deduces from (*) that

$$\langle u, 1 \rangle_z = \mathrm{Res}_x \left(\mathrm{Tr}(u) \det(c_{ij}) \frac{dx_1 \cdots dx_n}{x_1 \cdots x_n} \right),$$

whence, by ([8] III 9 R6),

$$\langle u, 1 \rangle_z = \mathrm{Tr}(u(x)) \det(c_{ij}(x)) = \mathrm{Tr}(u(x)) \det(1 - dF_x)^{-1}.$$

The corollary therefore follows from 6.11.1.

Remark 6.12.1. If X^F is assumed only finite, the preceding calculation shows that one has

$$\sum_i (-1)^i \mathrm{Tr}((F, u), H^i(X, L)) = \sum_{x \in X^F} \mathrm{Res}_x \left(\mathrm{Tr}(u) \frac{dx_1 \cdots dx_n}{(x_1 - F_1) \cdots (x_n - F_n)} \right),$$

where (x_i) is a system of local coordinates at x, and the F_i are the coordinates of F (near x) in this system.

The reader will convince himself, moreover, that the preceding formula is still valid if X is proper and is assumed only to be smooth at the points of X^F.

6.13

Assume that S is the spectrum of an algebraic closure of the finite field $\mathbb{F}_q$ and that X/S is obtained by extension of scalars from a proper smooth scheme $X_0/\mathbb{F}_q$. Take for F the Frobenius endomorphism of X/S "defined by raising coordinates to the q-th power". One has $X^F = X_0(\mathbb{F}_q)$, and X^F consists of transverse points since $dF = 0$. If L is a locally free sheaf of finite type on X and $u \in \mathrm{Hom}(F^*L, L)$, the Woods-Hole formula is therefore written as

$$\sum_i (-1)^i \mathrm{Tr}((F, u), H^i(X, L)) = \sum_{x \in X_0(\mathbb{F}_q)} \mathrm{Tr}(u_x, L_x). \tag{6.13.1}$$

In particular, for $L = \mathcal{O}_X$, and u the canonical isomorphism $F^*\mathcal{O}_X \xrightarrow{\sim} \mathcal{O}_X$, one finds:

$$\sum_i (-1)^i \mathrm{Tr}(F, H^i(X, \mathcal{O}_X)) = \mathrm{Card}(X_0(\mathbb{F}_q)) \pmod p. \tag{6.13.2}$$

Artin-Schreier theory makes it possible to rewrite the first member in the form $\sum_i (-1)^i \mathrm{Tr}(F, H^i(X, \mathbb{F}_p))$, where $H^*(X, \mathbb{F}_p)$ denotes the étale cohomology of X with values in the constant sheaf $\mathbb{F}_p$. By a

refinement of this argument, Deligne, in (SGA $4^{1/2}$ Fonctions L), deduced from 6.13.1 the following generalization of 6.13.2:

Theorem 6.13.3 (Deligne). Let X_0 be a separated scheme of finite type over $\mathbb{F}_q$, let X be the scheme deduced from X_0 by extension of scalars to an algebraic closure k of $\mathbb{F}_q$, and let F be the Frobenius endomorphism of X/k. Then, for every $L_0 \in \operatorname{ob} D_{\mathrm{ctf}}(X_0, \mathbb{F}_p)$, if L denotes the inverse image of L_0 on X, one has

$$\sum_i (-1)^i \operatorname{Tr}(F, H^i_c(X, L)) = \sum_{x \in X^F} \operatorname{Tr}(F, L_x).$$

Let us point out that the particular case of 6.13.3 corresponding to $L_0 = \mathbb{F}_p$ was established by Katz in (SGA 7 XXII) by a completely different method, based on Dwork's calculation of the zeta function of a hypersurface. Moreover, 6.13.2 in the proper smooth case is also an immediate consequence of the Lefschetz formula in crystalline cohomology ([5] VII 3.1.9). In fact, crystalline cohomology gives the more precise information that each factor $\det(1 - Ft, H^i(X_0/W)) \in W[t]$ of the zeta function is congruent mod p to $\det(1 - Ft, H^i(X_0, \mathcal{O}_{X_0}))$ (at least if $H^*(X_0/W)$ is torsion-free). Katz showed [11] that, using estimates of B. Mazur [14], one could obtain higher congruences (involving the $H^i(X_0, \Omega^j_{X_0})$ and the Cartier operator) for smooth hypersurfaces (or complete intersections) for which the Hodge numbers (in the interesting dimension) are assumed to vanish up to a certain level.

On the other hand, if X_0 is a proper scheme over $\mathbb{F}_q$, geometrically integral, and such that $H^i(X_0, \mathcal{O}_{X_0}) = 0$ for $i > 0$, the Lefschetz-Verdier formula 6.7.2, applied to $X = X_0 \otimes k$ and the Frobenius endomorphism of X, immediately implies that X_0 has at least one rational point over $\mathbb{F}_q$ (since $\operatorname{Tr}(F, R\Gamma(X, \mathcal{O}_X)) = 1$). Serre asks whether this conclusion is still true when one replaces $\mathbb{F}_q$ by a field satisfying (C_1) ([17] II 3), for example $\mathbb{C}(t)$ (Tsen), or $\mathbb{C}((t))$ (Lang) (see loc. cit. for other examples); indeed, he observes that if X_0 is a complete intersection of multidegree $(m_1, \ldots, m_r)$ in $\mathbb{P}^n$, the condition of triviality of cohomology is equivalent ([16] no. 78) to the condition $m_1 + \cdots + m_r < n + 1$, which is also the condition that occurs when one writes condition (C_1).

6.14

The Woods Hole formula has many other applications, for which we refer to [2] and to Beauville's exposé [4].

6.15

The editor has not examined the case of components of fixed points of dimension ≥ 1, but it is not impossible that one could deduce from 6.7.2 (probably conjugated with Riemann-Roch) Lefschetz-Riemann-Roch formulae in the style of those of Donovan [7], Iversen [10], Nielsen [15] (at least with values in the base field). Nor is it impossible, on the other hand, that the formula 6.7.2, applied over the dual numbers, might provide residue formulae for vector fields analogous to those of Bott [6], [3].

Exposé III B
Calculations of Local Terms

by Luc Illusie

Introduction

This exposé, written in January 1977, does not correspond to any oral exposé of the seminar. It comprises two independent parts. In the first, we compute the Lefschetz–Verdier local terms for cohomological correspondences between smooth curves over an algebraically closed field, supported on correspondences satisfying certain general-position hypotheses. The formula that we obtain gives as corollaries Verdier's formula [6] for transversal endomorphisms (which applies in particular to the case of the Frobenius endomorphism), and the formula stated by Langlands in ([4] 7.12). The method of proof is parallel to that followed by Artin–Verdier in [6]. One reduces to proving the vanishing of the local term when the given complexes of sheaves have zero fibre at the images of the fixed point under consideration, and in fact one proves a stronger property, namely that a certain restriction map is zero (2.5). To establish this property, one first reduces to the tamely ramified case by covers of the same degree of the two given curves (so as not to destroy the general-position hypotheses), and then treats this case directly by means of Abhyankar's lemma and the relative purity theorem. The second part of this exposé, of a much more technical nature, is inspired by the method used by Grothendieck to establish the Lefschetz formula for certain cohomological correspondences on curves (see XII and (SGA $4^{1/2}$ Rapport)). In no. 5, for complexes of modules on a topos, we develop a theory of non-commutative traces which generalizes the commutative theory of (SGA 6 I) and, in the case of a punctual topos, recovers the non-commutative theory developed by Grothendieck in the oral seminar (this was written up in Exposé XI, unfortunately lost). We apply the techniques of no. 5 to define, in no. 6, Lefschetz–Verdier local terms for cohomological correspondences between complexes of modules over rings that are not necessarily commutative. These local terms behave like non-commutative traces and make it possible, in particular when one takes as base ring the algebra of a group, to divide canonically the ordinary local terms attached to equivariant correspondences. As an application, we prove Grothendieck's divisibility conjecture of (XII 4.5), in a more general form. We also show that the local terms defined by Grothendieck in the Lefschetz formula of XII are indeed the Lefschetz–Verdier local terms, and we generalize the formula of (loc. cit.).

I thank P. Deligne for the useful suggestions he made to me during many discussions; I am particularly grateful to him for having pointed out, and helped me correct, an error in an early proof of Theorem 1.2.

Summary

5. Non-commutative traces 25
6. Equivariant correspondences and divisibility of local terms 46

I. Correspondences in General Position between Curves

In this part, S denotes the spectrum of an algebraically closed field k of characteristic p, and Λ a noetherian commutative ring killed by an integer prime to p. For every scheme X over S we denote by $D(X)$ the derived category of sheaves of Λ-modules on X, and by $D_{\mathrm{ctf}}(X)$ the full subcategory of $D(X)$ formed by complexes of finite tor-dimension and constructible cohomology.

1. Statement of the theorem and corollaries

1.1

Let X (resp. Y) be the strict localization, at a closed point, of a smooth separated S-curve, let A (resp. B) be a strictly local S-scheme, and let

$$a : A \longrightarrow X \times_S Y, \qquad b : B \longrightarrow X \times_S Y$$

be S-morphisms. We denote by $p_1 : X \times_S Y \to X$, $p_2 : X \times_S Y \to Y$ the projections, put $a_i = p_i a$, $b_i = p_i b$, and denote by x (resp. y) the closed point of X (resp. Y). We assume that a_2 and b_1 are finite and surjective, and that $A \times_{(X \times_S Y)} B$ is reduced to the closed point z whose image in $X \times_S Y$ is (x, y).

Let $L \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$, $M \in \mathrm{ob}\, D_{\mathrm{ctf}}(Y)$, $u \in \mathrm{Hom}(a_1^* L, a_2^! M)$, and $v \in \mathrm{Hom}(b_2^* M, b_1^! L)$. Denote by

$$u_z \in \mathrm{Hom}(L_x, M_y) \qquad (\text{resp. } v_z \in \mathrm{Hom}(M_y, L_x))$$

the composite homomorphism

$$L_x = R\Gamma(X, L) \xrightarrow{a_1^*} R\Gamma(A, a_1^* L) \xrightarrow{R\Gamma(A,u)} R\Gamma(A, a_2^! M) \xrightarrow{a_{2*}} R\Gamma(Y, M) = M_y,$$

where a_{2*} is defined by the adjunction map $a_{2*} a_2^! M \to M$ (resp. the analogous composite homomorphism defined by means of (b, v)). Since L_x and M_y are perfect complexes of Λ-modules, one can form the cup-product (SGA 6 I 8.3)

$$\langle u_z, v_z \rangle = \mathrm{Tr}(u_z v_z) = \mathrm{Tr}(v_z u_z) \in \Lambda. \tag{1.1.1}$$

Put $\Lambda_X(1)[2] = K_X$, $\Lambda_Y(1)[2] = K_Y$. By (I 5) (or (SGA $4^{1/2}$ Duality 1, or Finitude 4.1)) the functor $D_X = \mathrm{RHom}(-, K_X)$ (resp. $D_Y = \mathrm{RHom}(-, K_Y)$) on $D_{\mathrm{ctf}}(X)$ (resp. $D_{\mathrm{ctf}}(Y)$) is dualizing, i.e. for

every $E \in \operatorname{ob} D_{\mathrm{ctf}}(X)$ (resp. $E \in \operatorname{ob} D_{\mathrm{ctf}}(Y)$), one has $E \xrightarrow{\sim} D_X D_X E$ (resp. $E \xrightarrow{\sim} D_Y D_Y E$). We shall sometimes write D instead of D_X, D_Y.

On the other hand, denote by $p_i^!$ the functor $p_i^*(-)(1)[2]$. We have trivially

$$K_X \otimes_S^{\mathbf{L}} M \xrightarrow{\sim} p_2^! M, \qquad L \otimes_S^{\mathbf{L}} K_Y \xrightarrow{\sim} p_1^! L,$$

and it follows from (III 2.3), by passage to the limit, that the Künneth maps analogous to (III 3.1.1)

$$DL \otimes_S^{\mathbf{L}} M \longrightarrow \mathrm{RHom}(p_1^* L, p_2^! M), \qquad L \otimes_S^{\mathbf{L}} DM \longrightarrow \mathrm{RHom}(p_2^* M, p_1^! L)$$

are isomorphisms. Since a_2 is finite, a is finite, and hence the functor $a^!$ is defined; one verifies easily that one has the transitivity isomorphism $a^! p_2^! = a_2^!$. By the induction formula for a (SGA 4 XVIII 3.1.12.2), one therefore has a canonical isomorphism analogous to (III 3.2.1)

$$a^! \mathrm{RHom}(p_1^* L, p_2^! M) \xrightarrow{\sim} \mathrm{RHom}(a_1^* L, a_2^! M),$$

whence an isomorphism

$$\mathrm{Hom}(a_1^* L, a_2^! M) \xrightarrow{\sim} H^0(X \times_S Y, a_* a^! (DL \otimes_S^{\mathbf{L}} M)). \tag{*}$$

Likewise one has an isomorphism

$$\mathrm{Hom}(b_2^* M, b_1^! L) \xrightarrow{\sim} H^0(X \times_S Y, b_* b^! (L \otimes_S^{\mathbf{L}} DM)). \tag{**}$$

As in (III 4.1.2), one defines a natural pairing

$$(DL \otimes_S^{\mathbf{L}} M) \otimes^{\mathbf{L}} (L \otimes_S^{\mathbf{L}} DM) \longrightarrow K_X \otimes_S^{\mathbf{L}} K_Y = \Lambda_{X \times_S Y}(2)[4] \overset{\text{dfn}}{=} K_{X \times_S Y}.$$

Composing with the pairing analogous to (III 4.2.3)

$$a_* a^! P \otimes^{\mathbf{L}} b_* b^! Q \longrightarrow c_* c^! (P \otimes^{\mathbf{L}} Q),$$

where $P = DL \otimes_S^{\mathbf{L}} M$, $Q = L \otimes_S^{\mathbf{L}} DM$, and $c : Z = A \times_{(X \times_S Y)} B \to X \times_S Y$ is the canonical projection, and taking into account the isomorphisms (*), (**), one deduces a pairing analogous to (III 4.2.5)

$$\langle\ ,\ \rangle : \mathrm{Hom}(a_1^* L, a_2^! M) \otimes \mathrm{Hom}(b_2^* M, b_1^! L) \longrightarrow H^0(X \times_S Y, c_* c^! K_{X \times_S Y}).$$

One verifies easily, by passage to the limit, that $c^! K_{X \times_S Y} = \Lambda_z$, so that $H^0(X \times_S Y, c_* c^! K_{X \times_S Y}) = \Lambda$. Thus one has a "cup-product"

$$\langle u, v \rangle \in \Lambda. \tag{1.1.2}$$

1.1.3

Let X' (resp. Y') be a smooth S-curve, A' (resp. B') a separated S-curve,

$$a' : A' \longrightarrow X' \times_S Y', \qquad b' : B' \longrightarrow X' \times_S Y'$$

finite S-morphisms, x' (resp. y') a closed point of X' (resp. Y'), z' an isolated closed point of $A' \times_{(X' \times_S Y')} B'$, with image s' (resp. t') in A' (resp. B'), and such that $a'_2 (= p_2 a')$ (resp. $b'_1 (= p_1 b')$) is quasi-finite at s' (resp. t'),

$$L' \in \operatorname{ob} D_{\mathrm{ctf}}(X'), \quad M' \in \operatorname{ob} D_{\mathrm{ctf}}(Y'), \quad u' \in \mathrm{Hom}(a_1'^* L', a_2'^! M'), \quad v' \in \mathrm{Hom}(b_2'^* M', b_1'^! L').$$

One can then consider the local term (III 4.2.7) $\langle u', v' \rangle_{z'} \in \Lambda$. On the other hand, if X, Y, A, B are the strict localizations of X', Y', A', B' at x', y', s', t', if $a : A \to X \times_S Y$, $b : B \to X \times_S Y$ are the morphisms deduced from a', b', if $L = L'|X$, $M = M'|Y$, and if $u \in \mathrm{Hom}(a_1^* L, a_2^! M)$, $v \in \mathrm{Hom}(b_2^* M, b_1^! L)$ are the maps deduced from u', v', then the data (X, Y, a, b, u, v) satisfy the hypotheses at the beginning of 1.1, and hence a cup-product 1.1.2 $\langle u, v \rangle \in \Lambda$ is defined. It follows from the compatibility of the formation of local terms (III 4.2.7) with localization (III 4.2.6) that $\langle u', v' \rangle_{z'} = \langle u, v \rangle$. It is also easy to see that any data (X, Y, a, b, u, v) satisfying the hypotheses at the beginning of 1.1 are induced by data $(X', Y', a', b', x', y', z', s', t', u', v')$ as above, where one may also assume, if desired, that $A' \times_{(X' \times_S Y')} B'$ is reduced to z'.

In general the cup-products 1.1.1 and 1.1.2 are unequal. Nevertheless one has the following theorem, which is the main result of this first part:

Theorem 1.2. Under the hypotheses at the beginning of 1.1, assume moreover that A and B are in general position, i.e. that the intersection of the tangent cones at (x, y) to the images of A and B in $X \times_S Y$ is reduced to (x, y), and that likewise A and $X \times \{y\}$ are in general position, as are $\{x\} \times Y$ and B. Then

$$\langle u_z, v_z \rangle = \langle u, v \rangle. \tag{1.2.1}$$

By the Lefschetz–Verdier formula (III 4.7), taking 1.1.3 into account, one deduces:

Corollary 1.3. Let F be an endomorphism of a proper smooth curve X/S such that the fixed-point scheme X^F is finite and formed of points where the graph of F is transverse to the diagonal. Let $L \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$, and $u \in \mathrm{Hom}(F^* L, L)$. Then

$$\mathrm{Tr}((F, u), R\Gamma(X, L)) = \sum_{x \in X^F} \mathrm{Tr}(u_x, L_x),$$

where the trace on both sides is taken in the sense of (SGA 6 I 8).

For L concentrated in degree 0, 1.3 is the result of Artin–Verdier ([6] 4.1). By a passage to the limit explained in XV, one deduces from 1.3 an analogous result in ℓ-adic cohomology ([6] 1.1), (XV §2 no. 3 prop. 2):

Corollary 1.3.1. With X and F as in 1.3, let L be a constructible $\mathbb{Q}_\ell$-sheaf on X (ℓ prime to p), and let $u \in \mathrm{Hom}(F^* L, L)$. Then:

$$\sum_i (-1)^i \mathrm{Tr}((F, u), H^i(X, L)) = \sum_{x \in X^F} \mathrm{Tr}(u_x, L_x).$$

The hypotheses of 1.3 and 1.3.1 apply in particular to the case where (F, u) is a Frobenius correspondence (XV 2), whence Grothendieck's trace formula ([2] 5.1), (SGA $4^{1/2}$ Rapport 3.2).

1.4

With the notation of 1.1, assume that b_2 and a_1 are finite and surjective (instead of a_2 and b_1), and consider the dual correspondences (III 5.1)

$$Du \in \mathrm{Hom}(a_2^* DM, a_1^! DL), \qquad Dv \in \mathrm{Hom}(b_1^* DL, b_2^! DM),$$

and the homomorphisms $(Du)_z \in \mathrm{Hom}((DM)_y, (DM)_x)$, $(Dv)_z \in \mathrm{Hom}((DL)_x, (DM)_y)$. Assume that $(A, \{x\} \times Y)$ is in general position, as are $(X \times \{y\}, B)$ and (A, B). Applying 1.2 to Du, Dv, one obtains

$$\langle Du, Dv \rangle = \langle (Du)_z, (Dv)_z \rangle,$$

whence, by (III 5.1.6) and (III 4.2.6),

$$\langle u, v \rangle = \langle (Du)_z, (Dv)_z \rangle. \tag{1.4.1}$$

From this remark and from 1.2 one deduces, by the Lefschetz–Verdier formula (III 4.7):

Corollary 1.5. Let X, Y be proper smooth curves over S,

$$a : A \longrightarrow X \times_S Y, \qquad b : B \longrightarrow X \times_S Y$$

correspondences where A and B are proper curves over S, let $L \in \mathrm{ob}\, D_{\mathrm{ctf}}(X)$, $M \in \mathrm{ob}\, D_{\mathrm{ctf}}(Y)$, $u \in \mathrm{Hom}(a_1^* L, a_2^! M)$, and $v \in \mathrm{Hom}(b_2^* M, b_1^! L)$. Assume that $C = A \times_{(X \times_S Y)} B$ is finite over S and of the form $C = C_1 \amalg C_2$, with the following properties: for $z \in C_1$, the morphisms deduced from a_2, b_1 by strict localization at the images of z are finite, and, if (x, y) denotes the image of z in $X \times_S Y$, each of the pairs (A, B), $(A, X \times \{y\})$, $(\{y\} \times Y, B)$ is in general position at (x, y); for $z \in C_2$, the morphisms deduced from a_1, b_2 by strict localization at the images of z are finite, and each of the pairs (A, B), $(A, \{x\} \times Y)$, $(B, X \times \{y\})$ is in general position at (x, y) ("general position" meaning that the intersection of the tangent cones at (x, y) to the images of the curves of the pair under consideration is reduced to (x, y)). Then, if $u_* \in \mathrm{Hom}(R\Gamma(X, L), R\Gamma(Y, M))$, $v_* \in \mathrm{Hom}(R\Gamma(Y, M), R\Gamma(X, L))$ are the morphisms defined by u, v (III 3.7.6), one has, with the notation of 1.1.1, (III 5.1.5),

$$\langle u_*, v_* \rangle = \sum_{z \in C_1} \langle u_z, v_z \rangle + \sum_{z \in C_2} \langle (Du)_z, (Dv)_z \rangle. \tag{1.5.1}$$

1.6

Assuming the formalism of ℓ-adic cohomology, one deduces from 1.5, by the passage-to-the-limit technique of XIV, that, under the hypotheses of 1.5 on X, Y, a, b, for $L \in \mathrm{ob}\, D^b(X, \mathbb{Q}_\ell)$ (ℓ prime $\neq p$), $M \in \mathrm{ob}\, D^b(Y, \mathbb{Q}_\ell)$, $u \in \mathrm{Hom}(a_1^* L, a_2^! M)$, $v \in \mathrm{Hom}(b_2^* M, b_1^! L)$, one has the analogue of 1.5.1 in $\mathbb{Q}_\ell$. This formula contains, as a special case, Proposition 7.12 of Langlands [4]: apply the formula with $X = Y$, M the sheaf F considered by Langlands; $L = \alpha M$ ($\alpha \in \mathbb{Q}_\ell^*$), A the diagonal of $X \times X$, b the correspondence ϕ of (loc. cit.), u the correspondence supported on A given by $\alpha^{-1} : L \to M$, v the correspondence Φ of (loc. cit.); with the notation of (loc. cit.), C_1 (resp. C_2) is the set of fixed points where $a < d$ (resp. $a > d$).

1.7

Under the hypotheses of 1.2, take for u (resp. v) the correspondence $\mathrm{cl}(A)$ (resp. $\mathrm{cl}(B)$) defined by $\mathrm{Tr}_{a_2} : a_{2*}\Lambda \to \Lambda$ (resp. $\mathrm{Tr}_{b_1} : b_{1*}\Lambda \to \Lambda$). Formula 1.2.1 becomes

$$\deg(a_2) \deg(b_1) = \langle \mathrm{cl}(A), \mathrm{cl}(B) \rangle, \tag{1.7.1}$$

where $\deg(a_2)$ (resp. $\deg(b_1)$) denotes the generic degree of a_2 (resp. b_1). Taking into account the hypotheses of general position, the left hand side of 1.7.1 is none other than the intersection multiplicity at (x, y) of the cycles a_*A, b_*B, the direct images of A and B. It is not difficult to deduce 1.7.1 directly from the compatibility of the formation of the cohomology class associated with a cycle with intersections (SGA $4^{1/2}$ Cycle 2.3.8).

2. Reduction to a vanishing theorem

2.1

Under the hypotheses of 1.1, let s (resp. t) denote the image of z in A (resp. B), and let $i : U = X - \{x\} \hookrightarrow X$ and $j : V = Y - \{y\} \hookrightarrow Y$ be the canonical inclusions. Since a_2 and b_1 are finite, one has $a_2^{-1}(y) = s$, $b_1^{-1}(x) = t$, hence

$$a_1^{-1}(U) \subset a_2^{-1}(V), \qquad b_2^{-1}(V) \subset b_1^{-1}(U),$$

and there are commutative diagrams

$$\begin{array}{ccccc} U & \xleftarrow{a_1'} & a_1^{-1}(U) & \xrightarrow{a_2'} & V \\ \downarrow{\scriptstyle i} & (1) & \downarrow & (2) & \downarrow{\scriptstyle j} \\ X & \xleftarrow[a_1]{} & A & \xrightarrow[a_2]{} & Y \end{array} \qquad \begin{array}{ccccc} U & \xleftarrow{b_1'} & b_2^{-1}(V) & \xrightarrow{b_2'} & V \\ \downarrow{\scriptstyle i} & (3) & \downarrow & (4) & \downarrow{\scriptstyle j} \\ X & \xleftarrow[b_1]{} & B & \xrightarrow[b_2]{} & Y, \end{array}$$

where squares (1) and (4) are cartesian.

Lemma 2.2. To prove 1.2, it is enough to consider the following two cases:

$$\text{a) } L_x = 0, \quad M_y = 0; \qquad \text{b) } L|U = 0, \quad M|V = 0.$$

Consider the decreasing filtrations on L and M defined by the subcomplexes

$$F^nL = \begin{cases} L, & n \leq 0, \\ i_!i^*L, & n = 1, \\ 0, & n > 1, \end{cases} \qquad F^nM = \begin{cases} M, & n \leq 0, \\ j_!j^*M, & n = 1, \\ 0, & n > 1. \end{cases}$$

The complex $a_{2*}a_1^*L$ (resp. $b_{1*}b_2^*M$) is then filtered by

$$F^n a_{2*}a_1^*L = a_{2*}a_1^*F^nL.$$

We have $F^n a_{2*}a_1^*L = a_{2*}a_1^*L$ for $n \leq 0$, and 0 for $n > 1$; moreover, since a_2 is finite and square (1) is cartesian,

$$F^1 a_{2*}a_1^*L = j_!(a_2')_!(a_1')^*i^*L.$$

Similarly,

$$F^n b_{1*}b_2^*M = \begin{cases} b_{1*}b_2^*M, & n \leq 0, \\ i_!(b_1')_!(b_2')^*j^*M, & n = 1, \\ 0, & n > 1. \end{cases}$$

We may suppose that u (resp. v) is defined by a homomorphism of complexes

$$u : a_{2*}a_1^*L \longrightarrow M \quad (\text{resp. } v : b_{1*}b_2^*M \longrightarrow L).$$

The preceding formulas show that the composite

$$F^1 a_{2*}a_1^*L \longrightarrow a_{2*}a_1^*L \xrightarrow{u} M$$

(resp. $F^1 b_{1*}b_2^*M \to b_{1*}b_2^*M \xrightarrow{v} L$) factors uniquely through F^1M (resp. F^1L); in other words, u (resp. v) is a homomorphism of filtered complexes. Thus u (resp. v) underlies a filtered correspondence, in the sense of (III 4.13), which we again denote by

$$u \in \mathrm{Hom}_{DF}(a_1^*L, a_2^!M), \qquad v \in \mathrm{Hom}_{DF}(b_2^*M, b_1^!L).$$

By additivity of cup-products ([3] V 3.8.7), (III 4.13.1), one has

$$\langle u_z, v_z\rangle = \langle \mathrm{gr}^0 u_z, \mathrm{gr}^0 v_z\rangle + \langle \mathrm{gr}^1 u_z, \mathrm{gr}^1 v_z\rangle,$$

and

$$\langle u, v\rangle = \langle \mathrm{gr}^0 u, \mathrm{gr}^0 v\rangle + \langle \mathrm{gr}^1 u, \mathrm{gr}^1 v\rangle.$$

The lemma follows, since $\mathrm{gr}^1 L = i_!i^*L$ (resp. $\mathrm{gr}^1 M = j_!j^*M$) has zero fibre at x (resp. y), whereas $\mathrm{gr}^0 L$ (resp. $\mathrm{gr}^0 M$) is concentrated at x (resp. y).

Lemma 2.3. Under the hypotheses of 1.1, suppose that $L|U = 0$ and $M|V = 0$. Then

$$\langle u_z, v_z\rangle = \langle u, v\rangle.$$

The idea of the proof is that then u and v are direct images of correspondences between complexes concentrated at the closed points, and that the formula to be proved merely expresses the Lefschetz formula for the projections $x \to S$, $y \to S$. In view of 1.1.3, the data of 1.1 may be replaced by the following data: X (resp. Y) is a smooth S-curve endowed with a closed point x (resp. y), A (resp. B) is a separated S-curve, $a : A \to X \times_S Y$, $b : B \to X \times_S Y$ are finite S-morphisms such that $A \times_{X\times_S Y} B$ is reduced to a closed point z above (x, y),

$$u \in \mathrm{Hom}(a_1^*L, a_2^!M), \qquad v \in \mathrm{Hom}(b_2^*M, b_1^!L),$$

with

$$L = h_{1*}L', \quad M = h_{2*}M', \quad L' \in \mathrm{ob}\, D_{\mathrm{ctf}}(\{x\}), \quad M' \in \mathrm{ob}\, D_{\mathrm{ctf}}(\{y\}),$$

where $h_1 : \{x\} \to X$ and $h_2 : \{y\} \to Y$ are the canonical inclusions. We must show that

$$\langle u_z, v_z\rangle = \langle u, v\rangle_z,$$

where

$$u_z \in \mathrm{Hom}(\mathrm{R}\Gamma(X, L), \mathrm{R}\Gamma(Y, M)), \qquad v_z \in \mathrm{Hom}(\mathrm{R}\Gamma(Y, M), \mathrm{R}\Gamma(X, L))$$

are defined as in 1.1, and $\langle u, v\rangle_z$ is the value at z of the cup-product (III 4.2.7). We have $\mathrm{R}\Gamma(X, L) = \mathrm{R}\Gamma_c(X, L) = L_x$, $\mathrm{R}\Gamma(Y, M) = \mathrm{R}\Gamma_c(Y, M) = M_y$, and u_z (resp. v_z) is nothing other than the direct image u_* (resp. v_*) of u (resp. v) on S in the sense of (III 3.7.6), as is shown by the calculation procedure (III 3.5 b)).

On the other hand, if $h = h_1 \times_S h_2 : (x,y) \to X \times_S Y$ is the inclusion, and if $a' : A' \to (x,y)$, $b' : B' \to (x,y)$ denote the fibres of a, b at (x,y), each reduced to a point, then there are canonical isomorphisms

$$h_* a'_* a'^{!}(DL_x \overset{\mathrm{L}}{\otimes}_\Lambda M_y) \xrightarrow{\sim} a_* a^{!}(DL \overset{\mathrm{L}}{\otimes}_\Lambda M),$$

$$h_* b'_* b'^{!}(L_x \overset{\mathrm{L}}{\otimes}_\Lambda DM_y) \xrightarrow{\sim} b_* b^{!}(L \overset{\mathrm{L}}{\otimes}_\Lambda DM),$$

and the arrows

$$h_* : \mathrm{Hom}(a_1'^{*} L_x, a_2'^{!} M_y) \to \mathrm{Hom}(a_1^{*} L, a_2^{!} M),$$

$$h_* : \mathrm{Hom}(b_2'^{*} M_y, b_1'^{!} L_x) \to \mathrm{Hom}(b_2^{*} M, b_1^{!} L)$$

(III 3.7.6) are isomorphisms. The correspondences u and v are therefore written uniquely as

$$u = h_* u', \qquad v = h_* v', \tag{1}$$

with

$$u' \in \mathrm{Hom}(a_1'^{*} L_x, a_2'^{!} M_y), \qquad v' \in \mathrm{Hom}(b_2'^{*} M_y, b_1'^{!} L_x).$$

By the Lefschetz formula (III 4.5.1) for $(h_1, h_2, A' \to A, B' \to B)$, one has

$$\langle u, v \rangle_z = \langle u', v' \rangle_z. \tag{2}$$

On the other hand, by (1), $u_* = u'_*$ and $v_* = v'_*$; hence, by the Lefschetz formula for $\{x\} \to S$, $\{y\} \to S$, one has

$$\langle u_*, v_* \rangle = \langle u', v' \rangle_z. \tag{3}$$

In view of the preceding remark, the conclusion follows by comparing (2) and (3).

Lemma 2.4. To prove 1.2, one may suppose that a and b are closed immersions, and it is enough to prove that, if $L_x = 0$ and $M_y = 0$, the restriction map

$$H^0_A(X \times_S Y, DL \overset{\mathrm{L}}{\otimes}_S M) \longrightarrow H^0_z(B, b^*(DL \overset{\mathrm{L}}{\otimes}_S M)) \tag{2.4.1}$$

is zero.

Put $X \times_S Y = Z$. The closed subschemes $a' : A' \to Z$, $b' : B' \to Z$, images of a and b, satisfy the same hypotheses as a and b. Let u' (resp. v') be the correspondence supported on A' (resp. B') which is the direct image of u (resp. v) by the arrow deduced from the adjunction arrow $f_* f^! \to 1$ (resp. $g_* g^! \to 1$), where $f : A \to A'$ (resp. $g : B \to B'$) is the projection. It is immediate that $u_z = u'_z$ and $v_z = v'_z$. On the other hand, it follows easily from the definition of the cup-product 1.1.2 that

$$\langle u, v \rangle = \langle u', v' \rangle,$$

hence the first assertion.

By 2.2 and 2.3, one may suppose that $L_x = 0$ and $M_y = 0$, and the conclusion of 1.2 then becomes $\langle u, v \rangle = 0$. Let $P, Q \in \mathrm{ob}\, D_{\mathrm{ctf}}(Z)$. The cup-product

$$H^0_A(Z, P) \otimes H^0_B(Z, Q) \longrightarrow H^0_z(Z, P \overset{\mathrm{L}}{\otimes} Q)$$

decomposes as

$$H^0_A(Z, P) \otimes H^0_B(Z, Q) \xrightarrow{b^* \otimes 1} H^0_z(B, b^* P) \otimes H^0_B(Z, Q) \longrightarrow H^0_z(Z, P \overset{\mathrm{L}}{\otimes} Q),$$

where b^* is the restriction and the second arrow, a variant of the product considered in (SGA $4^{1/2}$ Cycle 1.2.1), is derived from the evident product at the level of sections of sheaves. This assertion is easily checked, for example by means of the flasque resolutions of (SGA 4 XVII 4.2). If $a' : \{z\} \to B$, $b' : \{z\} \to A$, $c : \{z\} \to Z$ are the inclusions, one may also invoke the standard decomposition of the Künneth arrow (III 4.2.1)

$$a'^! P \overset{\mathrm{L}}{\otimes}_Z b'^! Q \longrightarrow c^!(P \overset{\mathrm{L}}{\otimes} Q)$$

into a "base-change arrow"

$$a'^! P \overset{\mathrm{L}}{\otimes}_Z b'^! Q \longrightarrow a'^! b^* P \overset{\mathrm{L}}{\otimes} a^* b'^! Q,$$

followed by "projection arrows"

$$a'^! b^* P \overset{\mathrm{L}}{\otimes} a^* b'^! Q \longrightarrow a'^!(b^* P \overset{\mathrm{L}}{\otimes} b'^! Q) \longrightarrow a'^! b'^!(P \overset{\mathrm{L}}{\otimes} Q)).$$

Taking $P = DL \overset{\mathrm{L}}{\otimes}_S M$, $Q = L \overset{\mathrm{L}}{\otimes}_S DM$, and returning to the definition of $\langle u, v \rangle$ (III 4.2.5), one sees that it is enough to prove that $b^* u = 0$, whence the conclusion.

In view of 2.4, 1.2 will therefore follow from the following more precise result.

Proposition 2.5. Under the hypotheses of 1.2, suppose that a and b are closed immersions and that $L_x = 0$, $M_y = 0$. Let T be the strict localization of $X \times_S Y$ at $z = (x, y)$, and identify A, B with closed subschemes of T. Then the restriction arrows

$$b^* : \mathrm{R}\Gamma_A(T, (DL \overset{\mathrm{L}}{\otimes}_S M)|T) \longrightarrow \mathrm{R}\Gamma_z(B, b^*(DL \overset{\mathrm{L}}{\otimes}_S M)),$$

$$a^* : \mathrm{R}\Gamma_B(T, (L \overset{\mathrm{L}}{\otimes}_S DM)|T) \longrightarrow \mathrm{R}\Gamma_z(A, a^*(L \overset{\mathrm{L}}{\otimes}_S DM))$$

are zero.

2.6

The proof of 2.5 will occupy the rest of number 2 and numbers 3 and 4. By symmetry of the statement, it is enough to prove the assertion concerning b^*. We shall rewrite it in a form which will be more convenient. First note that

$$\mathrm{R}\Gamma(T, (DL \overset{\mathrm{L}}{\otimes}_S M)|T) = (DL \overset{\mathrm{L}}{\otimes}_S M)_z = (DL)_x \overset{\mathrm{L}}{\otimes} M_y = 0,$$

because $M_y = 0$, and similarly

$$\mathrm{R}\Gamma(B, b^*(DL \overset{\mathrm{L}}{\otimes}_S M)) = (DL \overset{\mathrm{L}}{\otimes}_S M)_z = 0.$$

Consequently, the relative cohomology triangles give isomorphisms

$$\mathrm{R}\Gamma(T - A, (DL \overset{\mathrm{L}}{\otimes}_S M)|T - A) \xrightarrow{\sim} \mathrm{R}\Gamma_A(T, (DL \overset{\mathrm{L}}{\otimes}_S M)|T)[1],$$

$$\mathrm{R}\Gamma(B - z, b^*(DL \overset{\mathrm{L}}{\otimes}_\Lambda M)|B - z) \xrightarrow{\sim} \mathrm{R}\Gamma_z(B, b^*(DL \overset{\mathrm{L}}{\otimes}_\Lambda M))[1],$$

under which the arrow b^* of 2.5, shifted by 1, is identified with the restriction

$$b^* : \mathrm{R}\Gamma(T - A, (DL \overset{\mathrm{L}}{\otimes}_S M)|T - A) \longrightarrow \mathrm{R}\Gamma(B - z, (DL \overset{\mathrm{L}}{\otimes}_S M)|B - z). \tag{2.6.1}$$

Since $L_x = 0$, $M_y = 0$, one may write

$$L = i_! DP, \qquad M = j_! Q, \tag{2.6.2}$$

where $i : X - x \to X$, $j : Y - y \to Y$ are the inclusions, and $P \in \mathrm{ob}\, D_{\mathrm{ctf}}(X - x)$, $Q \in \mathrm{ob}\, D_{\mathrm{ctf}}(Y - y)$. By the duality isomorphism (SGA 4 XVIII 3.19.6), together with passage to the limit, one has

$$DL = Ri_* DDP = Ri_* P,$$

hence

$$DL \overset{\mathrm{L}}{\otimes}_S M = Ri_* P \overset{\mathrm{L}}{\otimes}_S j_! Q.$$

Put $X \times_S Y = Z$, and identify $X \times \{y\}$ and $\{x\} \times Y$ with closed subschemes of Z (resp. T), which we shall simply denote by X and Y. Let

$$f' : Z - Y \hookrightarrow Z, \qquad g' : Z - (X \cup Y) \hookrightarrow Z - Y,$$

$$f : T - Z \hookrightarrow T, \qquad g : T - (X \cup Y) \hookrightarrow T - Y$$

be the inclusions. The Künneth formula (III 1.6.4) gives, by passage to the limit,

$$DL \overset{\mathrm{L}}{\otimes}_S M = Rf'_* g'_! (P \overset{\mathrm{L}}{\otimes}_S Q),$$

and hence

$$(DL \overset{\mathrm{L}}{\otimes}_S M)|T = Rf_* g_! ((P \overset{\mathrm{L}}{\otimes}_S Q)|T - (X \cup Y)). \tag{2.6.3}$$

With this identification, 2.6.1 becomes

$$b^* : \mathrm{R}\Gamma(T - (Y \cup A), g_!(E)|T - (Y \cup A)) \longrightarrow \mathrm{R}\Gamma(B - z, g_!(E)|B - z), \tag{2.6.4}$$

where

$$E = (P \overset{\mathrm{L}}{\otimes}_S Q)|T - (X \cup Y).$$

In the next two numbers, we shall show that the arrow 2.6.4 is zero: first we shall reduce to the case where the cohomology sheaves of E have tame ramification, more precisely where the inertia action occurs through an ℓ-group, for a prime number $\ell \neq p$, and then we shall treat that case directly by means of a purity theorem.

3. Reduction to the tame case

3.1

Recall that the base ring Λ is annihilated by an integer prime to p, hence is a direct product of noetherian rings Λ_i, each Λ_i being annihilated by a power of a prime number $\ell_i \neq p$. For every scheme S' over S, the derived category $D(S', \Lambda)$ is the product of the categories $D(S', \Lambda_i)$, so that, in order to prove the vanishing of 2.6.4, we may suppose that Λ is annihilated by a power of a prime number $\ell \neq p$. We may also suppose that P (resp. Q) is bounded and has locally free components of finite type.

3.2

Put $X - x = U$, $Y - y = V$. Let U''/U be a finite Galois covering with group G which trivializes the components of P, let H be an ℓ-Sylow subgroup of G, let $U' = U''/H$ be the quotient covering, and let X' be the normalized strictly local trait of X in U'. Then X'/X is a finite connected covering of degree d_1 prime to ℓ, and the representation of $\pi_1(U')$ defined by the components of $P' = P|U'$ factors through a finite ℓ-group. Proceeding similarly with Q, one finds a finite connected covering Y'/Y of degree d_2 prime to ℓ, inducing on V an étale covering V' such that the representation of $\pi_1(V')$ defined by the components of $Q' = Q|V'$ factors through a finite ℓ-group. Let

$$d = d_1 e_1 = d_2 e_2 = \operatorname{lcm}(d_1, d_2).$$

After adjoining an e_1-th root (resp. an e_2-th root) of a uniformizer of X' (resp. Y'), we may suppose that X' (resp. Y') has the same properties as above, and moreover that $d_1 = d_2 = d$.

Let x' (resp. y') be the closed point of X' (resp. Y'), T' the strict localization of $X' \times_S Y'$ at (x', y'), z' the closed point of T', A' (resp. B') the inverse image of A (resp. B) in T', and

$$E' = (P \overset{\mathrm{L}}{\otimes}_\Lambda Q)|T' - (X' \cup Y') = (P' \overset{\mathrm{L}}{\otimes}_\Lambda Q')|T' - (X' \cup Y').$$

We then have a commutative square of restriction arrows

$$\begin{array}{ccc} \mathrm{R}\Gamma(T - (Y \cup A), g_!(E)|T - (Y \cup A)) & \xrightarrow{b^*} & \mathrm{R}\Gamma(B - z, g_!(E)|B - z) \\ \downarrow & & \downarrow (1) \\ \mathrm{R}\Gamma(T' - (Y' \cup A'), g'_!(E')|T' - (Y' \cup A')) & \xrightarrow{b'^*} & \mathrm{R}\Gamma(B' - z', g'_!(E')|B' - z'), \end{array}$$

where $b' : B' \to T'$, $g' : T' - (X' \cup Y') \to T' - Y'$ are the inclusions. The covering T'/T is finite, of degree d^2, and étale outside $X \cup Y$, hence induces an étale covering of degree d^2 from $B' - z'$ onto $B - z$. The composite of (1) and the trace morphism

$$\mathrm{R}\Gamma(B' - z', g'_!(E')|B' - z') \longrightarrow \mathrm{R}\Gamma(B - z, g_!(E)|B - z)$$

is therefore multiplication by d^2, which is an isomorphism, since ℓ does not divide d. To prove that the arrow 2.6.4 is zero, it is therefore enough to prove that $b'^* = 0$. We are thus reduced to the case where the representation of $\pi_1(U)$ (resp. $\pi_1(V)$) defined by the components of P (resp. Q) factors through a finite ℓ-group, provided one ensures that A', B' satisfy the general-position hypotheses of 1.2. This will follow from the following lemma.

Lemma 3.3. Under the hypotheses of 1.2, a and b being closed immersions, let X'/X, Y'/Y be finite coverings of strictly local S-traits, of the same degree d. Let A' (resp. B') denote the inverse image of A (resp. B) in $X' \times_S Y'$. Then the pairs (A', B'), (A', X'), (Y', B') are each in general position in the sense of 1.2.[14]

The proof of 3.3 will be given after a few preliminaries.

Lemma 3.4. Let $X \xleftarrow{s_1} W \xrightarrow{s_2} Y$ be finite morphisms of S-traits, let $s = (s_1, s_2) : W \to X \times_S Y$, and let u, v, w be uniformizers of X, Y, W respectively, so that

$$s_1^* u = a w^m \pmod{w^{m+1}}, \qquad s_2^* v = b w^n \pmod{w^{n+1}},$$

[14] With the usual abuse of notation $X' = X' \times \{y'\}$, etc. (where x' (resp. y') is the closed point of X' (resp. Y').

with $a, b \in k^*$. Then: (i) if $m < n$, $s(W)$ is tangent to X at $z = (x, y)$; (ii) if $m = n$, $s(W)$ is tangent to the subscheme of $X \times_S Y$ with equation

$$ap_2^*(v) - bp_1^*(u) = 0.$$

Let $Z = X \times_S Y$, and let W' be the reduced closed subscheme which is the image of s. In the tangent space to Z at z, the slope, with respect to the tangent to X, of the tangent to W' is the value at the origin of the function induced on W' by $p_2^*(v)/p_1^*(u)$; this is also the value at the origin of the function induced by $p_2^*(v)/p_1^*(u)$ on W, and is therefore 0 (resp. b/a) in case (i) (resp. (ii)).

In the situation of 3.4, we shall define the slope of W with respect to $((X, u), (Y, v))$ as the element of $k \cup \{\infty\}$ equal to 0 if $m < n$, to ∞ if $m > n$, and to b/a if $m = n$. This element is independent of the choice of w.

Lemma 3.5. Let $f : X' \to X$, $g : Y' \to Y$ be finite morphisms of S-traits with the same ramification index d, and let u, v, u', v' be uniformizers of X, Y, X', Y' respectively. Then there exists $C \in k^*$ such that, for every commutative diagram of finite morphisms of S-traits

$$\begin{array}{ccccc} X' & \xleftarrow{s_1'} & W' & \xrightarrow{s_2'} & Y' \\ & & \downarrow{\scriptstyle h} & & \downarrow{\scriptstyle g} \\ X & \xleftarrow[s_1]{} & W & \xrightarrow[s_2]{} & Y, \end{array}$$

one has $\lambda = C\lambda'^d$, where λ (resp. λ') is the slope of W (resp. W') with respect to $((X, u), (Y, v))$ (resp. $((X', u'), (Y', v'))$).

By hypothesis,

$$f^*u = \alpha u'^d \pmod{u'^{d+1}}, \qquad g^*v = \beta v'^d \pmod{v'^{d+1}},$$

with $\alpha, \beta \in k^*$. We show that $C = \beta/\alpha$ has the required properties. Let w (resp. w') be a uniformizer of W (resp. W'). We have

$$s_1^*u = aw^m \pmod{w^{m+1}}, \qquad s_2^*v = bw^n \pmod{w^{n+1}},$$

$$s_1'^*u' = a'w'^{m'} \pmod{w'^{m'+1}}, \qquad s_2'^*v' = b'w'^{n'} \pmod{w'^{n'+1}},$$

$$h^*w = \gamma w'^r \pmod{w'^{r+1}},$$

with $a, b, a', b', \gamma \in k^*$. Commutativity of the squares in the diagram implies

$$m'd = rm, \qquad n'd = rn,$$

hence $m'/n' = m/n$. Suppose first that $m = n$. Then $\lambda = b/a$, $\lambda' = b'/a'$. If $N = m'd = rm = n'd = rn$, the preceding congruences give

$$(fs_1')^*u = \alpha a'^d w'^N \pmod{w'^{N+1}}, \qquad (s_1h)^*u = a\gamma^m w'^N \pmod{w'^{N+1}},$$

whence $\alpha a'^d = a\gamma^m$. Similarly $\beta b'^d = b\gamma^m$, whence $\lambda = C\lambda'^d$, for $\lambda \neq 0, \infty$. But, since $m'/n' = m/n$, $\lambda = 0$ (resp. ∞) is equivalent to $\lambda' = 0$ (resp. ∞), which completes the proof.

We now prove 3.3. Let $Z = X \times_S Y$, $Z' = X' \times_S Y'$, let $\widetilde{A}$ (resp. $\widetilde{B}$) be the normalization of A (resp. B), and let $\widetilde{A}'$ (resp. $\widetilde{B}'$) be the normalization of A' (resp. B'). Since $\widetilde{A}'$ (resp. $\widetilde{B}'$) is also the normalization of $\widetilde{A} \times_Z Z'$ (resp. $\widetilde{B} \times_Z Z'$), we have commutative squares

$$\begin{array}{ccccc} \widetilde{A}' & \longrightarrow & Z' & \longleftarrow & \widetilde{B}' \\ \downarrow & & \downarrow & & \downarrow \\ \widetilde{A} & \longrightarrow & Z & \longleftarrow & \widetilde{B}. \end{array} \tag{*}$$

Let $(x_i)_{1\le i\le m}$ (resp. $(y_j)_{1\le j\le n}$) be the points of $\widetilde{A}$ (resp. $\widetilde{B}$) above x (resp. y), and let $(x'_i)_{1\le i\le m'}$ (resp. $(y'_j)_{1\le j\le n'}$) be the points of $\widetilde{A}'$ (resp. $\widetilde{B}'$) above x' (resp. y'). Since A and B are strictly local, we have decompositions

$$\widetilde{A} = \coprod_{1\le i\le m} A_i, \qquad \widetilde{B} = \coprod_{1\le j\le n} B_j, \qquad \widetilde{A}' = \coprod_{1\le i\le m'} A'_i, \qquad \widetilde{B}' = \coprod_{1\le j\le n'} B'_j,$$

where A_i, B_j, A'_i, B'_j are strictly local traits with respective closed points x_i, y_j, x'_i, y'_j. Choose uniformizers u, v, u', v' of X, Y, X', Y' respectively; let λ_i (resp. μ_j) be the slope of A_i (resp. B_j) with respect to $((X,u),(Y,v))$, and let λ'_i (resp. μ'_j) be that of A'_i (resp. B'_j) with respect to $((X',u'),(Y',v'))$. The general-position hypotheses on A and B are expressed by

$$\lambda_i \ne 0 \text{ for all } i, \qquad \mu_j \ne \infty \text{ for all } j, \qquad \lambda_i \ne \mu_j \text{ for all } i,j, \tag{1}$$

and we have to show that

$$\lambda'_i \ne 0 \text{ for all } i, \qquad \mu'_j \ne \infty \text{ for all } j, \qquad \lambda'_i \ne \mu'_j \text{ for all } i,j. \tag{2}$$

Let $i' \in [1,m']$, $j' \in [1,n']$, and let x_i (resp. y_j) be the image of $x'_{i'}$ (resp. $y'_{j'}$). The preceding diagram provides commutative squares of finite morphisms of S-traits

$$\begin{array}{ccccc} X' & \longleftarrow & A'_{i'} & \longrightarrow & Y' \\ & & \downarrow & & \downarrow \\ X & \longleftarrow & A_i & \longrightarrow & Y \end{array} \qquad \begin{array}{ccccc} X' & \longleftarrow & B'_{j'} & \longrightarrow & Y' \\ & & \downarrow & & \downarrow \\ X & \longleftarrow & B_j & \longrightarrow & Y. \end{array}$$

By 3.5, there exists $C \in k^*$ such that

$$\lambda_i = C{\lambda'_{i'}}^d, \qquad \mu_j = C{\mu'_{j'}}^d.$$

Thus (1) implies (2), which completes the proof of 3.3.

4. End of the proof of 1.2

4.1

To complete the proof of 2.5, hence of 1.2, it remains to establish the vanishing of 2.6.4 under the following additional hypotheses: Λ is annihilated by a power of a prime number $\ell \ne p$, and

P and Q are bounded, with locally free components of finite type, such that the corresponding representations of the fundamental groups factor through finite ℓ-groups. We have

$$g_!(E)|T-(Y\cup A) = g_{1!}(E_1),$$

where $g_1 : T-(X\cup Y\cup A)\hookrightarrow T-(Y\cup A)$ is the inclusion, and

$$E_1 = (P \overset{\mathrm{L}}{\otimes}_\Lambda Q)|T-(X\cup Y\cup A).$$

Now E_1 is a complex with bounded, constructible, locally constant cohomology such that the corresponding representation of $\pi_1(T-(X\cup Y\cup A))$ factors through an ℓ-group. The assertion to be proved will therefore follow from the following more general statement.

Proposition 4.2. Let T be the strict localization at a closed point of a smooth S-scheme of dimension 2, let t be the closed point of T, and let A, B, X be closed subschemes of dimension 1 of T. Let $i : T-(A\cup X)\hookrightarrow T-A$ be the inclusion. Suppose that X is regular, and that A is in general position with respect to B and X; that is, the intersection of the tangent cones at t to A and $B\cup X$ is reduced to t. Let $E\in \mathrm{ob}\, D^b(T-(A\cup X))$ be such that $H^*(E)$ is constructible and locally constant, and that the corresponding representation of $\pi_1(T-(A\cup X))$ factors through an ℓ-group. Then the restriction arrow

$$\mathrm{R}\Gamma(T-A, i_!(E)) \longrightarrow \mathrm{R}\Gamma(B-t, i_!(E)|B-t)$$

is zero.

The proof will rely on the following lemma.

Lemma 4.3. Let Z be a connected regular noetherian scheme of dimension 2, with residual characteristics prime to ℓ, and let X, Y be regular divisors meeting transversely at a point z, giving a diagram of inclusions

$$\begin{array}{ccc} Z-(X\cup Y) & \xrightarrow{i'} & Z-Y \\ \downarrow{\scriptstyle j} & & \downarrow{\scriptstyle j} \\ Z-X & \xrightarrow[i]{} & Z \\ \downarrow{\scriptstyle m} & & \downarrow{\scriptstyle m} \\ Y-z & \xrightarrow[i_1]{} & Y. \end{array}$$

Assume the purity hypothesis

$$(P)\qquad R^q j_*(\mathbb{Z}/\ell) = 0 \quad \text{for } q>1.$$

Let $L\in \mathrm{ob}\, D^b(Z-(X\cup Y),\Lambda)$ have constructible locally constant cohomology, with the corresponding representation of $\pi_1(Z-(X\cup Y))$ factoring through an ℓ-group. Then:

a) There is a canonical isomorphism

$$i_{1!}m'^* Rj_* i'^*_! L \xrightarrow{\sim} m^* Rj_*(i'^*_! L),$$

and the complex $m'^* Rj_* i'^*_! L$ has constructible, locally constant cohomology.

b) Suppose that Y is connected, and let $\bar{s}$ be a geometric point of Y localized at a closed point $s \neq z$. Then the restriction arrow

$$\mathrm{R}\Gamma(Y, m^* R j_*(i'_! L)) \longrightarrow (R j_*(i'_! L))_{\bar{s}} \tag{4.3.1}$$

is zero.

c) Under the hypotheses of b), let C be a closed subscheme of dimension 1 of Z such that $Y \cap C = s$, and let $\widetilde{C}$ be the strict localization of C at $\bar{s}$. Then the restriction arrow

$$\mathrm{R}\Gamma(Z - Y, i'_! L) \longrightarrow \mathrm{R}\Gamma(\widetilde{C} - \bar{s}, i'_!(L)|\widetilde{C} - \bar{s}) \tag{4.3.2}$$

is zero.

The trivial isomorphism

$$i^* R j_* i'_! L \xrightarrow{\sim} R j_*(i'^* i'_! L) = R j_* L$$

gives an isomorphism

$$m'^* R j_* i'_! L \xrightarrow{\sim} i_1^* m^* R j_* i'_! L,$$

hence, by adjunction, an arrow

$$i_{1!} m'^* R j_* i'_! L \longrightarrow m^* R j_*(i'_! L),$$

which induces an isomorphism outside z. We show that it is an isomorphism, that is, that if $\bar{z}$ is a geometric point above z, then

$$(R j_*(i'_! L))_{\bar{z}} = 0.$$

For this, one may replace Λ by $\mathbb{Z}/\ell^\nu$, where ℓ^ν annihilates Λ, and by dévissage and passage to the limit reduce to the case where L is a locally constant $\mathbb{Z}/\ell^\nu$-module of finite type corresponding to a representation of π_1 through an ℓ-group. Since the only finite abelian group of ℓ-torsion which is simple under the action of an ℓ-group is $\mathbb{Z}/\ell$ with trivial action, a further dévissage reduces to the case where L is the constant sheaf $\mathbb{Z}/\ell$.

Let $\widetilde{Z}$ be the strict localization of Z at $\bar{z}$, $\widetilde{X} = X \times_Z \widetilde{Z}$, $\widetilde{Y} = Y \times_Z \widetilde{Z}$, and let $i' : \widetilde{Z} - (\widetilde{X} \cup \widetilde{Y}) \hookrightarrow \widetilde{Z} - \widetilde{Y}$ be the inclusion. One has

$$(R j_*(i'_!(\mathbb{Z}/\ell)))_{\bar{z}} = \mathrm{R}\Gamma(\widetilde{Z} - \widetilde{Y}, i'_!(\mathbb{Z}/\ell)),$$

so it remains to prove that the restriction arrow

$$H^n(\widetilde{Z} - \widetilde{Y}, \mathbb{Z}/\ell) \longrightarrow H^n(\widetilde{X} - \bar{z}, \mathbb{Z}/\ell)$$

is an isomorphism for all n. For $n \leq 1$ this is a consequence of Abhyankar's lemma, and for $n > 1$ both sides vanish by the purity hypothesis. The first assertion of a) is therefore proved. We prove the second. By dévissage, we may suppose L concentrated in degree 0. The hypothesis (P) implies, by dévissage, that $R^q j_* L = 0$ for $q > 2$. It remains to prove constructibility and local constancy of $m'^* R^q j_* i'_! L$ for $q \leq 1$, which is standard. For constructibility, resolving L on the right by sheaves of the form $p_* p^* L$, where $p : Z' \to Z$ is a finite covering tamely ramified along Y, reduces to the case where L is constant, of value L_0: then

$$m'^* j_* i'_! L = (L_0)_{Y-z}, \qquad m'^* R^1 j_* i'_! L = (L_0)_{Y-z}(-1)$$

by Abhyankar. For local constancy, one has to see that the specialization arrows are isomorphisms. One may, for this, replace Λ by $\mathbb{Z}/\ell^\nu$ as above, and then reduce by dévissage to the case where L is the constant sheaf $\mathbb{Z}/\ell$; the conclusion follows from Abhyankar's lemma.

We have therefore proved a). We prove b). Let $\bar\eta$ be a geometric generic point of Y. Choose specialization arrows

$$a : \bar\eta \to Y(\bar z), \qquad b : \bar\eta \to Y(\bar s),$$

where $Y(\bar z)$ (resp. $Y(\bar s)$) is the strict localization of Y at $\bar z$ (resp. $\bar s$). Put

$$M = m^* R j_*(i'_! L).$$

The commutative square

$$\begin{array}{ccc} Y & \longrightarrow & Y(\bar s) \\ \uparrow & & \uparrow{\scriptstyle b} \\ Y(\bar z) & \xrightarrow[a]{} & \bar\eta \end{array}$$

induces a commutative square

$$\begin{array}{ccc} \mathrm{R}\Gamma(Y, M) & \xrightarrow{4.3.1} & M_{\bar s} \\ \downarrow & & \downarrow{\scriptstyle b^*} \\ M_{\bar z} & \xrightarrow[a^*]{} & M_{\bar\eta}. \end{array}$$

Since $M|Y - z$ has locally constant cohomology, b^* is an isomorphism. On the other hand, since $M = i_{1!} i_1^* M$, one has $M_{\bar z} = 0$, hence the arrow 4.3.1 is zero. It remains to prove c). We have $\widetilde C = C \times_Z \widetilde Z$, where $\widetilde Z$ denotes, as above, the strict localization of Z at $\bar z$. Put $\widetilde Y = Y \times_Z \widetilde Z$. Then there is a commutative diagram of restriction arrows

$$\begin{array}{ccc} \mathrm{R}\Gamma(Z - Y, i'_! L) = \mathrm{R}\Gamma(Z, R j_*(i'_! L)) & \xrightarrow{4.3.2} & \mathrm{R}\Gamma(\widetilde C - \bar s, i'_!(L)|\widetilde C - \bar s) \\ \downarrow & & \uparrow \\ \mathrm{R}\Gamma(Y, m^* R j_*(i'_! L)) & \xrightarrow[4.3.1]{} & (R j_*(i'_! L))_{\bar s} = \mathrm{R}\Gamma(\widetilde Z - \widetilde Y, (i'_! L)|\widetilde Z - \widetilde Y) \end{array}$$

The vanishing of 4.3.2 therefore follows from b), completing the proof of 4.3.

We prove 4.2. Let $f : T' \to T$ be the blowing-up of the maximal ideal of T, let $D = f^{-1}(z) (\simeq \mathbb{P}^1_S)$ be the exceptional divisor, and let A', B', X' be the respective strict transforms of A, B, X. Then T' is regular, connected, of dimension 2, X' is a regular divisor meeting D transversely at one point z', and the general-position hypotheses on A, B, X mean that A' is disjoint from $B' \cup X'$. Let E' be the inverse image of E on $T' - (A' \cup D \cup X')$, and let

$$i' : T' - (A' \cup D \cup X') \hookrightarrow T' - (A' \cup D)$$

be the inclusion. We must prove that the restriction arrow

$$\mathrm{R}\Gamma(T' - (A' \cup D), i'_!(E')) \longrightarrow \mathrm{R}\Gamma(B' \cup D, i'_!(E')|B' - (B' \cup D)) \qquad (*)$$

is zero. But B' is a disjoint union of strictly local schemes B'_j $(1 \le j \le n)$, of dimension 1, such that for every j, $B'_j \cap D$ is reduced to a point b_j. Applying 4.3 c) to $(Z = T' - A', X = X', Y =$

$D-(D\cap A'), L=E', C=B'_j$), the hypothesis (P) being verified by virtue of the relative purity theorem (SGA 4 XVI 3), since (Z,Y) is a filtered projective limit of smooth pairs of codimension 1 over S, with affine étale transition morphisms, one obtains that the restriction arrow

$$\mathrm{R}\Gamma(T'-(A'\cup D), i'_!(E')) \longrightarrow \mathrm{R}\Gamma(B'_j-b_j, i'_!(E')|B'_j-b_j)$$

is zero. Therefore (*) is zero, which completes the proof of 4.2, hence of 2.5 and 1.2.

II. Equivariant correspondences

5. Non-commutative traces

Throughout this number, fix a topos T and a commutative unital ring K of T. The rings under consideration will be assumed associative and unital, but not necessarily commutative. By a K-algebra we shall mean any (associative, unital) ring A of T endowed with a (unital) homomorphism $K\to A$ whose image is contained in the center.

5.0. Introduction

Let E be a K-module locally a direct factor of a free module of finite type. There is then a trace homomorphism, local in nature,

$$\mathrm{Tr}_K : \underline{\mathrm{Hom}}_K(E,E)\longrightarrow K, \tag{5.0.1}$$

defined by composing the evaluation arrow

$$\underline{\mathrm{Hom}}_K(E,K)\otimes_K E\longrightarrow K,\qquad f\otimes x\longmapsto f(x), \tag{5.0.2}$$

with the inverse of the canonical tensor-product isomorphism

$$\underline{\mathrm{Hom}}_K(E,K)\otimes_K E\longrightarrow \underline{\mathrm{Hom}}_K(E,E),\qquad f\otimes y\longmapsto (x\longmapsto f(x)y). \tag{5.0.3}$$

The arrows 5.0.2 and 5.0.3 are defined more generally for every K-module E, and from them one obtains, for every complex of K-modules E, homomorphisms of complexes

$$\underline{\mathrm{Hom}}^\bullet_K(E,K)\otimes_K E\longrightarrow K,\qquad f\otimes x\longmapsto f(x), \tag{5.0.4}$$

$$\underline{\mathrm{Hom}}^\bullet_K(E,K)\otimes_K E\longrightarrow \underline{\mathrm{Hom}}^\bullet_K(E,E),\qquad f\otimes y\longmapsto (x\longmapsto f(x)y). \tag{5.0.5}$$

Upon deriving, 5.0.4 and 5.0.5 give, for $E\in \mathrm{ob}\, D^-(K)$, arrows in $D(K)$

$$\underline{\mathrm{RHom}}_K(E,K)\overset{\mathrm{L}}{\otimes}_K E\longrightarrow K, \tag{5.0.6}$$

$$\underline{\mathrm{RHom}}_K(E,K)\overset{\mathrm{L}}{\otimes}_K E\longrightarrow \underline{\mathrm{RHom}}_K(E,E). \tag{5.0.7}$$

If E is perfect (SGA 6 I), 5.0.7 is an isomorphism, as is readily checked by reduction to the case $E=K$, and, by composing the inverse of 5.0.7 with 5.0.6, one obtains a trace homomorphism, global in nature,

$$\mathrm{Tr}_K : \underline{\mathrm{RHom}}_K(E,E)\longrightarrow K, \tag{5.0.8}$$

which generalizes 5.0.1 (for more details, see SGA 6 I 7, 8).

We propose here to examine to what extent, in the preceding constructions, K can be replaced by a K-algebra A (we shall be interested chiefly in the case where A is the K-algebra of an ordinary finite group), and in particular to define a trace arrow analogous to 5.0.8, generalizing the notion of non-commutative trace introduced by Stallings in [5] and developed by Grothendieck in Exposé XI of this seminar. As was said in the introduction, that exposé, written by I. Bucur, was unfortunately lost; the reader may nevertheless refer to Deligne's exposé (SGA $4^{1/2}$, Rapport), where the essential points are indicated. Although replacing K by A in 5.0.3 presents no difficulty, the same is not true in 5.0.2: if E is a left A-module, the evaluation arrow

$$\underline{\mathrm{Hom}}_A(E,A)\otimes_K E \longrightarrow A, \qquad f\otimes x \longmapsto f(x),$$

does not in general factor through $\underline{\mathrm{Hom}}_A(E,A)\otimes_A E$, but, upon passage to the quotient, gives an arrow

$$\underline{\mathrm{Hom}}_A(E,A)\otimes_A E \longrightarrow A_\natural, \tag{5.0.9}$$

where $A_\natural$ is the quotient K-module of A by the sub-K-module locally generated by local sections of the form $ab-ba$. If E is locally a direct factor of a free left A-module of finite type, the tensor-product arrow, analogous to 5.0.3,

$$\underline{\mathrm{Hom}}_A(E,A)\otimes_A E \longrightarrow \underline{\mathrm{Hom}}_A(E,E) \tag{5.0.10}$$

is an isomorphism, and, by composing the inverse of 5.0.10 with 5.0.9, one obtains a trace homomorphism

$$\mathrm{Tr}_A : \underline{\mathrm{Hom}}_A(E,E) \longrightarrow A_\natural, \tag{5.0.11}$$

which reduces to 5.0.1 when $A=K$. One also checks readily (see 5.7) that, when T is punctual, 5.0.11 coincides with the trace homomorphism of Stallings and Grothendieck. In this number we shall examine the extension to complexes and the derivation of the arrows 5.0.9, 5.0.10, 5.0.11, and the behavior of the resulting arrows with respect to extension and restriction of scalars and to certain external tensor products. In fact, we shall derive arrows slightly more general than 5.0.9 and 5.0.10, so that the constructions may be applied, in no. 6, to the definition of "non-commutative" Lefschetz–Verdier local terms.

5.1. Notation

If A is a K-algebra, we denote by A° the algebra opposite to A, and by $A^e = A\otimes_K A^\circ$ the enveloping algebra of A. Giving an A-bimodule, a left A^e-module, or a right A^e-module amounts to the same thing. In particular, A is an A-bimodule, and hence both a left and a right A^e-module. If E is a bimodule, recall ([1] IX 4) that

$$H_0(A,E) = A\otimes_{A^e} E = E\otimes_{A^e} A$$

is the quotient K-module of E by the sub-K-module locally generated by local sections of the form $ax-xa$, for $x\in E$, $a\in A$[15]. We shall sometimes write $E_\natural$ instead of $H_0(A,E)$. In particular, $A_\natural$ is the K-module defined in 5.0.9. If $A=K[G]$, where G is an ordinary finite group, $A_\natural$ is simply the free K-module on the set $G_\natural$ of conjugacy classes of G.

[15] If M is a sheaf, the notation $x\in M$ means that x is a local section of M.

If A, B are K-algebras, we shall use the Cartan–Eilenberg notation ${}_AE$, E_B, ${}_AE_B$ to denote respectively a left A-module, a right B-module, and a module that is left over A and right over B. Finally, we shall denote by $D(A)$ (resp. $D(A,B)$) the derived category of the category of left A-modules (resp. of A-B-bimodules, left over A and right over B).

5.2

Let A, B be K-algebras. Recall that, in the situation $({}_AE, {}_BF_A, {}_BG)$, there is a canonical isomorphism

$$\underline{\mathrm{Hom}}_A(E, \underline{\mathrm{Hom}}_B(F,G)) \xrightarrow{\sim} \underline{\mathrm{Hom}}_B(F \otimes_A E, G), \qquad f \longmapsto (y \otimes x \longmapsto f(x)(y)). \tag{5.2.1}$$

This derives to an isomorphism

$$\underline{\mathrm{RHom}}_A(E, \underline{\mathrm{RHom}}_B(F,G)) \xrightarrow{\sim} \underline{\mathrm{RHom}}_B(F \overset{\mathrm{L}}{\otimes}_A E, G) \tag{5.2.2}$$

for $E \in \mathrm{ob}\, D^-(A)$, $F \in \mathrm{ob}\, D(B,A)$, $G \in \mathrm{ob}\, D^+(B)$. Indeed, one may suppose that E is bounded above with flat terms and that G is bounded below with injective terms; one then has $\underline{\mathrm{RHom}}_B(F \overset{\mathrm{L}}{\otimes}_A E, G) = \mathrm{Hom}^\bullet_B(F \otimes_A E, G)$, $\underline{\mathrm{RHom}}_B(F,G) = \mathrm{Hom}^\bullet_B(F,G)$, and $\underline{\mathrm{RHom}}_A(E, \mathrm{Hom}^\bullet_B(F,G)) = \mathrm{Hom}^\bullet_A(E, \mathrm{Hom}^\bullet_B(F,G))$, since, if E is acyclic, $F \otimes_A E$ is acyclic, and hence $\mathrm{Hom}^\bullet_A(E, \mathrm{Hom}^\bullet_B(F,G)) \simeq \mathrm{Hom}^\bullet_B(F \otimes_A E, G)$ is acyclic. For E and G as above, 5.2.2 is given by the isomorphism of complexes

$$\mathrm{Hom}^\bullet_A(E, \mathrm{Hom}^\bullet_B(F,G)) \xrightarrow{\sim} \mathrm{Hom}^\bullet_B(F \otimes_A E, G)$$

defined by 5.2.1. Note that, if A and B are flat over K, 5.2.2 still holds under the conditions $E \in \mathrm{ob}\, D(A)$, $F \in \mathrm{ob}\, D^-(B,A)$, $G \in \mathrm{ob}\, D^+(B)$, as is seen by resolving F by flat $(B \otimes_K A^\circ)$-modules. From 5.2.2 one deduces an isomorphism

$$\underline{\mathrm{Hom}}_A(E, \underline{\mathrm{RHom}}_B(F,G)) \xrightarrow{\sim} \underline{\mathrm{Hom}}_B(F \overset{\mathrm{L}}{\otimes}_A E, G). \tag{5.2.3}$$

5.3

Let A be a K-algebra. In the situation $(E_A, {}_AF)$, there is a canonical isomorphism

$$E \otimes_A F \xrightarrow{\sim} (E \otimes_K F) \otimes_{A^e} A, \qquad x \otimes y \longmapsto (x \otimes y) \otimes 1. \tag{5.3.1}$$

On the other hand, in the situation $({}_AE, {}_AF_A)$, the evaluation arrow

$$\underline{\mathrm{Hom}}_A(E,F) \otimes_K E \longrightarrow F, \qquad f \otimes x \longmapsto f(x) \tag{5.3.2}$$

is A^e-linear, and therefore induces, via 5.3.1, upon applying $- \otimes_{A^e} A$, an arrow

$$\underline{\mathrm{Hom}}_A(E,F) \otimes_A E \longrightarrow F \otimes_{A^e} A \ (= F_\natural). \tag{5.3.3}$$

In other words, the composite of 5.3.2 and the canonical arrow $F \to F_\natural$, $x \mapsto x \otimes 1$, factors uniquely through 5.3.3.

Suppose that A is flat over K. Then 5.3.1 derives to an isomorphism

$$E \overset{\mathrm{L}}{\otimes}_A F \xrightarrow{\sim} (E \overset{\mathrm{L}}{\otimes}_K F) \overset{\mathrm{L}}{\otimes}_{A^e} A \tag{5.3.4}$$

for $E \in \mathrm{ob}\, D^-(A^\circ)$, $F \in \mathrm{ob}\, D^-(A)$ (resolve E and F by flat modules). On the other hand, 5.3.3 derives to an arrow of $D(K)$, called the evaluation arrow,

$$\underline{\mathrm{RHom}}_A(E,F) \overset{\mathrm{L}}{\otimes}_A E \longrightarrow F \overset{\mathrm{L}}{\otimes}_{A^e} A, \tag{5.3.5}$$

for $E \in \mathrm{ob}\, D^-(A)$, $F \in \mathrm{ob}\, D^b(A^e)$ such that $\underline{\mathrm{RHom}}_A(E,F) \in \mathrm{ob}\, D^b(A^\circ)$. One first derives 5.3.2 to an arrow of $D^-((A^e)^\circ)$,

$$\underline{\mathrm{RHom}}_A(E,F) \overset{\mathrm{L}}{\otimes}_K E \longrightarrow F, \tag{5.3.6}$$

by resolving E by flat modules and F by injective A^e-modules, and then one applies the functor $- \overset{\mathrm{L}}{\otimes}_{A^e} A$ to 5.3.6, taking 5.3.4 into account.

5.4

Let A be a K-algebra. In the situation $({}_AE, {}_AF_A, {}_AG)$, there is a canonical arrow

$$\underline{\mathrm{Hom}}_A(E,F) \otimes_A G \longrightarrow \underline{\mathrm{Hom}}_A(E, F \otimes_A G), \qquad u \otimes y \longmapsto (x \longmapsto u(x) \otimes y), \tag{5.4.1}$$

which corresponds by adjunction (5.2.1) to the A-linear arrow

$$E \otimes_K \underline{\mathrm{Hom}}_A(E,F) \otimes_A G \longrightarrow F \otimes_A G$$

defined by the evaluation arrow $E \otimes_K \underline{\mathrm{Hom}}_A(E,F) \to F$. The arrow 5.4.1 derives to an arrow of $D(K)$, called the tensor-product arrow,

$$\underline{\mathrm{RHom}}_A(E,F) \overset{\mathrm{L}}{\otimes}_A G \longrightarrow \underline{\mathrm{RHom}}_A(E, F \overset{\mathrm{L}}{\otimes}_A G), \tag{5.4.2}$$

for $E \in \mathrm{ob}\, D^-(A)$, $F \in \mathrm{ob}\, D^+(A^e)$, $G \in \mathrm{ob}\, D^-(A)$, with $F \overset{\mathrm{L}}{\otimes}_A G \in \mathrm{ob}\, D^+(A)$. If E and G are bounded above with flat terms, and F is bounded below with injective terms, the first member of 5.4.2 identifies with $\mathrm{Hom}^\bullet_A(E,F) \otimes_A G$, and it is sent to the second member by the composite of 5.4.1 and the natural arrow

$$\mathrm{Hom}^\bullet_A(E, F \otimes_A G) \longrightarrow \underline{\mathrm{RHom}}_A(E, F \otimes_A G) = \underline{\mathrm{RHom}}_A(E, F \overset{\mathrm{L}}{\otimes}_A G).$$

The arrow 5.4.2 is not an isomorphism in general. It is, however, an isomorphism in certain important cases, for example if E is perfect (as is checked by reducing to $E = A$). We shall see another interesting example later (6.2.3).

The arrows 5.3.5 and 5.4.2 will play an essential role throughout the rest of the exposé. The examples of objects F that we have in mind are: a) $F = A$, or $F = A$ regarded as a right A-module in the natural way and as a left A-module through a homomorphism of K-algebras $\varphi : A \to A$ (cf. 5.13); b) $F = M \overset{\mathrm{L}}{\otimes}_K A$, with $M \in \mathrm{ob}\, D^+(K)$; in no. 6, M will be a dualizing complex, see especially 6.3.2, 6.4.1, 6.5.6.

5.5

Denote by $DF(A)$ the derived category of complexes of left A-modules endowed with a finite filtration ([3] V). Then, in the situation of 5.2, there is a canonical isomorphism in $DF(K)$, analogous to 5.2.2, for $E \in \mathrm{ob}\, D^-F(A)$, $F \in \mathrm{ob}\, D^-F(B,A)$ $(= D^-F(B \otimes_K A^\circ))$, $G \in \mathrm{ob}\, D^+F(B)$. Similarly, there are "filtered derived" arrows analogous to 5.3.4, 5.3.5, 5.3.6, 5.4.2. These arrows are compatible with passage to associated graded objects, in the sense of ([3] V 1,2).

5.6

Assume that A is flat over K. Denote by $D(A)_{\mathrm{parf}}$ the full subcategory of $D(A)$ formed by complexes of finite perfect amplitude, that is, perfect complexes of finite tor-dimension (SGA 6 I). We define a canonical arrow, called the trace,

$$\mathrm{Tr}_A = \underline{\mathrm{RHom}}_A(E, F \overset{\mathrm{L}}{\otimes}_A E) \longrightarrow F \overset{\mathrm{L}}{\otimes}_{A^e} A \tag{5.6.1}$$

for $E \in \mathrm{ob}\, D(A)_{\mathrm{parf}}$, $F \in \mathrm{ob}\, D^b(A^e)$, by composing the inverse isomorphism of 5.4.2 for $G = E$ with the evaluation arrow 5.3.5. From this one deduces a trace arrow

$$\mathrm{Tr}_A : \underline{\mathrm{Hom}}_A(E, F \overset{\mathrm{L}}{\otimes}_A E) \longrightarrow H^0(T, F \overset{\mathrm{L}}{\otimes}_{A^e} A). \tag{5.6.2}$$

For $F = A$, by composing with the canonical arrow $A \overset{\mathrm{L}}{\otimes}_{A^e} A \to A \otimes_{A^e} A = A_\natural$ (5.1), one obtains arrows, again called traces,

$$\mathrm{Tr}_A : \underline{\mathrm{RHom}}_A(E, E) \longrightarrow A_\natural, \tag{5.6.3}$$

$$\mathrm{Tr}_A : \underline{\mathrm{Hom}}_A(E, E) \longrightarrow H^0(T, A_\natural). \tag{5.6.4}$$

Notice that 5.6.4 is a rather innocuous arrow, local in nature, whereas 5.6.3 is a "serious" arrow, global in nature.

Denote by $DF(A)_{\mathrm{parf}}$ the full subcategory of $DF(A)$ formed by filtered complexes whose associated graded object has finite perfect amplitude. Then there is an arrow in $DF(K)$ analogous to 5.6.1 for $E \in \mathrm{ob}\, DF(A)_{\mathrm{parf}}$, $F \in \mathrm{ob}\, D^b F(A^e)$, whence arrows analogous to 5.6.2, 5.6.3, 5.6.4. It follows from the remarks in 5.5 that the filtered arrow 5.6.1 is compatible with passage to the associated graded object (cf. [3] V 3.7.2), and one deduces, as in loc. cit., that, if the filtration on F is concentrated in degree 0, then, for $u \in \mathrm{Hom}_{DF(A)}(E, F \overset{\mathrm{L}}{\otimes}_A E)$, one has

$$\mathrm{Tr}_A(u) = \sum_i \mathrm{Tr}_A(\mathrm{gr}^i u). \tag{5.6.5}$$

This formula implies in particular that, for $E \in \mathrm{ob}\, D(A)_{\mathrm{parf}}$, $F \in \mathrm{ob}\, D^b(A^e)$, $u \in \underline{\mathrm{Hom}}_A(E, F \overset{\mathrm{L}}{\otimes}_A E)$, one has

$$\mathrm{Tr}(u[1]) = -\mathrm{Tr}(u), \tag{5.6.6}$$

where $u[1] : E[1] \to (F \overset{\mathrm{L}}{\otimes}_A E)[1]$ is the translate of u.

5.7

The traces defined in 5.6 simultaneously generalize the usual commutative traces ((SGA 6 I), ([3] V 3)) and the non-commutative traces of Stallings [5] and Grothendieck.

(a) Suppose that $A = K$. Then $A^e = A_\natural = K$, the arrow 5.6.1 is written

$$\mathrm{Tr}_K : \underline{\mathrm{RHom}}_K(E, F \overset{\mathrm{L}}{\otimes}_K E) \longrightarrow F$$

and coincides with the trace arrow defined in ([3] V 3.7.1), in the special case where the complex K of loc. cit. is reduced to A. In particular,

$$\mathrm{Tr}_K : \underline{\mathrm{RHom}}_K(E, E) \longrightarrow K$$

coincides with the trace defined in (SGA 6 I 8).

(b) Assume again that A is a flat K-algebra, not necessarily commutative. We propose to make 5.6.4 explicit for E strictly perfect, that is, bounded with terms locally direct factors of free modules of finite type. First, take $E = A$; $\underline{\mathrm{RHom}}_A(A, A) = \underline{\mathrm{Hom}}_A(A, A)$ identifies with A by $f \mapsto f(1)$, $a \mapsto (x \mapsto xa)$, and 5.6.3 identifies with the canonical projection $A \to A_\natural$, which we shall denote by $a \mapsto a_\natural$; thus, if d_a denotes right multiplication by a,

$$\mathrm{Tr}_A(d_a) = a_\natural. \tag{5.7.1}$$

For $1 \leq i \leq n$, let E_i be a copy of A, and let $E = \bigoplus_{1\leq i\leq n} E_i$. The isomorphism 5.4.2, for $F = A$, $G = E$, is written

$$\bigoplus_{1\leq i,j\leq n} \underline{\mathrm{Hom}}_A(E_i, A) \otimes_A E_j \longrightarrow \underline{\mathrm{Hom}}_A(E, E),$$

and, for $u = \sum u_{ij} \otimes 1 \in \underline{\mathrm{Hom}}_A(E, E)$ ($u_{ij} \otimes 1 \in \underline{\mathrm{Hom}}_A(E_i, A) \otimes_A E_j$), one has

$$\mathrm{Tr}_A(u) = \sum_i (u_{ii})_\natural, \tag{5.7.2}$$

by definition of the evaluation arrow 5.3.5. Now take for E a direct factor of A^n, the image of a projector p, and denote by $i : E \to A^n$ the inclusion; then, for $u \in \underline{\mathrm{Hom}}_A(E, E)$, one has

$$\mathrm{Tr}_A(u) = \mathrm{Tr}_A(iup), \tag{5.7.3}$$

as is seen either with the aid of 5.6.5 or directly from the definition. Finally, suppose that E is strictly perfect; if $u \in \mathrm{Hom}_A(E, E)$ is a homomorphism of complexes, one has, by 5.6.5 and 5.6.6,

$$\mathrm{Tr}_A(u) = \sum_i (-1)^i \mathrm{Tr}_A(u^i). \tag{5.7.4}$$

The fact that 5.6.4 is obtained, by applying H^0, from a homomorphism of complexes $\underline{\mathrm{Hom}}^\bullet_A(E, E) \to A$ (5.6.3) implies that, if u, $v \in \mathrm{Hom}_A(E, E)$ are homotopic, then

$$\mathrm{Tr}_A(u) = \mathrm{Tr}_A(v). \tag{5.7.5}$$

Since every endomorphism of E in $D(A)$ is locally defined by an endomorphism of complexes, locally unique up to homotopy (SGA 6 I 4.10), the formulas 5.7.2 to 5.7.4 therefore permit the calculation of $\mathrm{Tr}_A(u)$ for every endomorphism u of E in $D(A)$ and, combined with 5.7.5, provide a direct definition of $\mathrm{Tr}_A(u)$. When the topos T is punctual, this recovers the definition of (SGA $4^{1/2}$, Rapport 4.3).

5.8

Let P, Q be A-bimodules. Then $P \otimes_A Q$ and $Q \otimes_A P$ are A-bimodules, and there are canonical isomorphisms

$$(P \otimes_A Q) \otimes_{A^e} A \xrightarrow{\sim} P \otimes_{A^e} Q \xrightarrow{\sim} (Q \otimes_A P) \otimes_{A^e} A \xrightarrow{\sim} A \otimes_{A^e} (P \otimes_K Q) \otimes_{A^e} A, \tag{5.8.1}$$

each of the objects above identifying canonically with the quotient K-module of $P \otimes_K Q$ by the submodule generated by sections of the form $axb \otimes y - x \otimes bya$, for $x \in P$, $y \in Q$, $a, b \in A$. For A flat over K, these isomorphisms derive to isomorphisms

$$(P \overset{\mathrm{L}}{\otimes}_A Q) \overset{\mathrm{L}}{\otimes}_{A^e} A \simeq P \overset{\mathrm{L}}{\otimes}_{A^e} Q \simeq (Q \overset{\mathrm{L}}{\otimes}_A P) \overset{\mathrm{L}}{\otimes}_{A^e} A \simeq A \overset{\mathrm{L}}{\otimes}_{A^e} (P \overset{\mathrm{L}}{\otimes}_K Q) \overset{\mathrm{L}}{\otimes}_{A^e} A \tag{5.8.2}$$

for $P, Q \in \operatorname{ob} D^-(A^e)$. On the other hand, the composition arrow at the level of modules

$$\underline{\operatorname{Hom}}_A(E, P \otimes_A F) \otimes_K \underline{\operatorname{Hom}}_A(F, Q \otimes_A E) \longrightarrow \underline{\operatorname{Hom}}_A(E, P \otimes_A Q \otimes_A E),$$

$$f \otimes g \longmapsto (P \otimes_A g)f,$$

derives to

$$\underline{\operatorname{RHom}}_A(E, P \overset{\mathrm{L}}{\otimes}_A F) \overset{\mathrm{L}}{\otimes}_K \underline{\operatorname{RHom}}_A(F, Q \overset{\mathrm{L}}{\otimes}_A E) \longrightarrow \underline{\operatorname{RHom}}_A(E, P \overset{\mathrm{L}}{\otimes}_A Q \overset{\mathrm{L}}{\otimes}_A E) \tag{5.8.3}$$

for $P, Q \in \operatorname{ob} D^b(A^e)$, $E, F \in \operatorname{ob} D^b(A)$ such that the tensor products and $\underline{\operatorname{RHom}}$'s appearing above belong to D^b. When E and F are perfect, this arrow identifies, via 5.4.2, with the arrow deduced from the evaluation arrow $F \overset{\mathrm{L}}{\otimes}_K \underline{\operatorname{RHom}}_A(F, Q) \to Q$; from this one readily deduces that there is a commutative square

$$\begin{array}{ccc} \underline{\operatorname{RHom}}_A(E, P \overset{\mathrm{L}}{\otimes}_A F) \overset{\mathrm{L}}{\otimes}_K \underline{\operatorname{RHom}}_A(F, Q \overset{\mathrm{L}}{\otimes}_A E) & \xrightarrow{(1)} & \underline{\operatorname{RHom}}_A(E, P \overset{\mathrm{L}}{\otimes}_A Q \overset{\mathrm{L}}{\otimes}_A E) \\ \downarrow{\scriptstyle (2)} & & \downarrow{\scriptstyle \mathrm{Tr}_A} \\ \underline{\operatorname{RHom}}_A(F, Q \overset{\mathrm{L}}{\otimes}_A P \overset{\mathrm{L}}{\otimes}_A F) & \xrightarrow[\mathrm{Tr}_A]{} & P \overset{\mathrm{L}}{\otimes}_{A^e} Q, \end{array} \tag{5.8.4}$$

where (1) and (2) are given by 5.8.3. The point is that the two composite arrows in 5.8.4 are defined by the tensor product of the evaluation arrows

$$F \overset{\mathrm{L}}{\otimes}_K \underline{\operatorname{RHom}}_A(F, Q) \longrightarrow Q, \qquad E \overset{\mathrm{L}}{\otimes}_K \underline{\operatorname{RHom}}_A(E, P) \longrightarrow P.$$

It follows that, for $u \in \underline{\operatorname{Hom}}_A(E, P \overset{\mathrm{L}}{\otimes}_A F)$, $v \in \underline{\operatorname{Hom}}_A(F, Q \overset{\mathrm{L}}{\otimes}_A E)$, one has

$$\mathrm{Tr}_A(vu) = \mathrm{Tr}_A(uv). \tag{5.8.5}$$

We shall sometimes denote the common value in 5.8.5 by $\langle u, v \rangle_A$.

5.9. Traces and extension of scalars

Let $A \to B$ be a morphism of flat K-algebras. It induces a morphism of K-algebras $A^e \to B^e$, hence an extension-of-scalars functor $- \overset{\mathrm{L}}{\otimes}_{A^e} B^e : D(A^e) \longrightarrow D(B^e)$. For E, F as in 5.3.5, if $F \overset{\mathrm{L}}{\otimes}_{A^e} B^e \in \operatorname{ob} D^b(B^e)$ and $\operatorname{RHom}_B(B \overset{\mathrm{L}}{\otimes}_A E, F \overset{\mathrm{L}}{\otimes}_{A^e} B^e) \in \operatorname{ob} D^b((B^e)^\circ)$, there is a commutative square in $D(K)$

$$\begin{array}{ccc} \operatorname{RHom}_A(E, F) \overset{\mathrm{L}}{\otimes}_{A^e} E & \xrightarrow{(1)} & F \overset{\mathrm{L}}{\otimes}_{A^e} A \\ \downarrow{\scriptstyle (3)} & & \downarrow{\scriptstyle (4)} \\ \operatorname{RHom}_B(B \overset{\mathrm{L}}{\otimes}_A E, F \overset{\mathrm{L}}{\otimes}_{A^e} B^e) \overset{\mathrm{L}}{\otimes}_{B^e} (B \overset{\mathrm{L}}{\otimes}_A E) & \xrightarrow[(2)]{} & (F \overset{\mathrm{L}}{\otimes}_{A^e} B^e) \overset{\mathrm{L}}{\otimes}_{B^e} B, \end{array} \tag{5.9.1}$$

where the arrows (1) and (2) are defined by 5.3.6, (4) by $A \to B$, and (3) by the canonical arrow $F \to F \overset{\mathrm{L}}{\otimes}_{A^e} B^e$. The verification is immediate. Similarly, for E, F, G as in 5.4.2, if $F \overset{\mathrm{L}}{\otimes}_{A^e} B^e \in \mathrm{ob}\, D^+(B^e)$ and $(F \overset{\mathrm{L}}{\otimes}_{A^e} B^e) \overset{\mathrm{L}}{\otimes}_B (B \overset{\mathrm{L}}{\otimes}_A G) \in \mathrm{ob}\, D^+(B)$, one has a commutative square in $D(K)$

$$\begin{array}{ccc} \mathrm{RHom}_A(E,F) \overset{\mathrm{L}}{\otimes}_A G & \xrightarrow{\quad (1) \quad} & \mathrm{RHom}_A(E, F \overset{\mathrm{L}}{\otimes}_A G) \\ \downarrow{\scriptstyle (3)} & & \downarrow{\scriptstyle (4)} \\ \mathrm{RHom}_B(B \overset{\mathrm{L}}{\otimes}_A E, F \overset{\mathrm{L}}{\otimes}_{A^e} B^e) \overset{\mathrm{L}}{\otimes}_B (B \overset{\mathrm{L}}{\otimes}_A G) & \xrightarrow[(2)]{} & \mathrm{RHom}_B(B \overset{\mathrm{L}}{\otimes}_A E, (F \overset{\mathrm{L}}{\otimes}_{A^e} B^e) \overset{\mathrm{L}}{\otimes}_B (B \overset{\mathrm{L}}{\otimes}_A G)), \end{array} \tag{5.9.2}$$

where (1) and (2) are defined by 5.4.2, and (3) and (4) by $F \to F \overset{\mathrm{L}}{\otimes}_{A^e} B^e$. From this one deduces, for E, F as in 5.6.1, with $F \overset{\mathrm{L}}{\otimes}_{A^e} B^e \in \mathrm{ob}\, D^b(B^e)$, a commutative square in $D(K)$, analogous to the preceding ones, in which the vertical arrows are defined by 5.6.1:

$$\begin{array}{ccc} \mathrm{RHom}_A(E, F \overset{\mathrm{L}}{\otimes}_A E) & \xrightarrow{\mathrm{Tr}_A} & F \overset{\mathrm{L}}{\otimes}_{A^e} A \\ \downarrow & & \downarrow \\ \mathrm{RHom}_B(B \overset{\mathrm{L}}{\otimes}_A E, (F \overset{\mathrm{L}}{\otimes}_{A^e} B^e) \overset{\mathrm{L}}{\otimes}_B (B \overset{\mathrm{L}}{\otimes}_A E)) & \xrightarrow[\mathrm{Tr}_B]{} & (F \overset{\mathrm{L}}{\otimes}_{A^e} B^e) \overset{\mathrm{L}}{\otimes}_{B^e} B. \end{array} \tag{5.9.3}$$

Finally, if one is given $F' \in \mathrm{ob}\, D^b(B^e)$ such that $\mathrm{RHom}_A(E, F') \in \mathrm{ob}\, D^b((B^\circ))$, and $f : F \overset{\mathrm{L}}{\otimes}_{A^e} B^e \to F'$, then there is a compatibility slightly more general than 5.9.1, expressed by an analogous commutative square, with F' in place of $F \overset{\mathrm{L}}{\otimes}_{A^e} B^e$ in the lower row and with the vertical arrows defined by f. One has similarly commutative squares analogous to 5.9.2 and 5.9.3 with F' in place of $F \overset{\mathrm{L}}{\otimes}_{A^e} B^e$. Taking in particular $F = A$ and, for $f : A \overset{\mathrm{L}}{\otimes}_{A^e} B^e \to B$, the arrow defined by $A \to B$, one obtains a commutative square

$$\begin{array}{ccc} \mathrm{RHom}_A(E,E) & \xrightarrow{\mathrm{Tr}_A} & A \overset{\mathrm{L}}{\otimes}_{A^e} A \\ \downarrow & & \downarrow \\ \mathrm{RHom}_B(B \overset{\mathrm{L}}{\otimes}_A E, B \overset{\mathrm{L}}{\otimes}_A E) & \xrightarrow[\mathrm{Tr}_B]{} & B \overset{\mathrm{L}}{\otimes}_{B^e} B, \end{array} \tag{5.9.4}$$

where the left vertical arrow, respectively the right vertical arrow, is given by extension of scalars, respectively is the canonical arrow deduced from $A \to B$.

5.10. Traces and restriction of scalars

Let $A \to B$ be a morphism of flat K-algebras such that B, as a left A-module, is flat and of finite presentation, i.e. locally a direct factor of a free A-module of finite type. This is the case for example if $A \to B$ is the morphism $K[H] \to K[G]$ defined by an injective morphism of discrete groups $H \hookrightarrow G$ of finite index. The scalar-restriction homomorphism

$$\mathrm{Hom}_B(B, B) \longrightarrow \mathrm{Hom}_A(B, B),$$

where B is considered as a left module, identifies, by the canonical isomorphisms

$$B \xrightarrow{\sim} \mathrm{Hom}_B(B,B), \qquad \mathrm{Hom}_A(B,A) \otimes_A B \xrightarrow{\sim} \mathrm{Hom}_A(B,B),$$

with an arrow of B-bimodules

$$B \longrightarrow \mathrm{Hom}_A(B,A) \otimes_A B. \tag{5.10.1}$$

The composite of 5.10.1 with the evaluation arrow $\mathrm{Hom}_A(B,A) \otimes_A B \to A_\natural$ (5.3.3) is the homomorphism $f \mapsto \mathrm{Tr}_A(f)$ $(= \mathrm{Tr}_A(d_f)$, where d_f is right multiplication by $f)$; hence, by the formula $\mathrm{Tr}_A(f_g) = \mathrm{Tr}_A(gf)$ (5.8.5), it factors through $B_\natural$ as an arrow again denoted $\mathrm{Tr}_{B/A} : B_\natural \to A_\natural$. Thus there is a commutative square

$$\begin{array}{ccc} B & \xrightarrow{\mathrm{Tr}_B} & B_\natural \\ {\scriptstyle 5.10.1}\downarrow & & \downarrow{\scriptstyle \mathrm{Tr}_{B/A}} \\ \mathrm{Hom}_A(B,A) \otimes_A B & \xrightarrow[\mathrm{ev}]{} & A_\natural. \end{array} \tag{5.10.2}$$

In the situation $({}_BE, {}^BP_A)$, one has a homomorphism of right B-modules

$$\mathrm{Hom}_B(E,P) \otimes_A B \longrightarrow \mathrm{Hom}_B(E, P \otimes_A B), \qquad u \otimes b \longmapsto (x \longmapsto u(x) \otimes b), \tag{5.10.3}$$

which is an isomorphism, as is checked immediately: it is enough to see that the underlying K-linear homomorphism is an isomorphism, and this follows from the fact that B is locally a direct factor of a free A-module of finite type. This isomorphism derives to an isomorphism of $D(B)$

$$\mathrm{RHom}_B(E,P) \overset{\mathrm{L}}{\otimes}_A B \xrightarrow{\sim} \mathrm{RHom}_B(E, P \overset{\mathrm{L}}{\otimes}_A B), \tag{5.10.4}$$

for $E \in \mathrm{ob}\, D^-(B)$, $P \in \mathrm{ob}\, D^+(B \otimes_K A^\circ)$: resolve E by modules of the form $B \otimes_A L$, where L is flat, and P by injective $(B \otimes_K A^\circ)$-modules, which are necessarily injective as B-modules, since A is flat over K; this allows one to remove the R on the left, and the resolution chosen for E also allows one to remove it on the right.

For $E \in \mathrm{ob}\, D^-(B)$, $M \in \mathrm{ob}\, D^+(K)$, $F \in \mathrm{ob}\, D^-(B)$, define an arrow in $D(K)$[16]

$$\mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_B F \longrightarrow \mathrm{RHom}_A(E, A \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_A F \tag{5.10.5}$$

as the composite of the arrows

$$\mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_B F \xrightarrow{(1)} \mathrm{RHom}_B(E, \mathrm{Hom}_A(B,A) \overset{\mathrm{L}}{\otimes}_A (B \overset{\mathrm{L}}{\otimes}_K M)) \overset{\mathrm{L}}{\otimes}_B F$$

$$\xrightarrow{(2)} \mathrm{RHom}_B(E, \mathrm{Hom}_A(B,A) \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_A B \overset{\mathrm{L}}{\otimes}_B F$$

$$\xrightarrow{(3)} \mathrm{RHom}_B(E, \mathrm{Hom}_A(B, A \overset{\mathrm{L}}{\otimes}_K M)) \overset{\mathrm{L}}{\otimes}_A F$$

$$\xrightarrow{(4)} \mathrm{RHom}_A(E, A \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_A F,$$

[16] In no. 6 we shall apply the constructions that follow to the case where M is a dualizing complex (6.7).

where (1) is defined by 5.10.1, (2) by the inverse isomorphism of 5.10.4 with $P = \mathrm{Hom}_A(B, A) \overset{\mathrm{L}}{\otimes}_K M$, (3) by the canonical isomorphism

$$\mathrm{Hom}_A(B, A) \overset{\mathrm{L}}{\otimes}_K M \xrightarrow{\sim} \mathrm{Hom}_A(B, A \overset{\mathrm{L}}{\otimes}_K M)$$

(5.4.2), and (4) by the adjunction isomorphism 5.2.2.

Proposition 5.10.6. Suppose that $M \overset{\mathrm{L}}{\otimes}_K F \in \mathrm{ob}\, D^+(B)$. Then there is a commutative square in $D(K)$

$$\begin{array}{ccc} \mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_B F & \xrightarrow{5.4.2} & \mathrm{RHom}_B(E, M \overset{\mathrm{L}}{\otimes}_K F) \\ \downarrow{\scriptstyle 5.10.5} & & \downarrow{\scriptstyle \mathrm{res}} \\ \mathrm{RHom}_A(E, A \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_A F & \xrightarrow[5.4.2]{} & \mathrm{RHom}_A(E, M \overset{\mathrm{L}}{\otimes}_K F), \end{array} \tag{5.10.7}$$

where the right vertical arrow is restriction of scalars.

One has to verify that there is a commutative square

$$\begin{array}{ccc} E \overset{\mathrm{L}}{\otimes}_K \mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_B F & \longrightarrow & M \overset{\mathrm{L}}{\otimes}_K F \\ \downarrow & & \downarrow{\scriptstyle \mathrm{res}} \\ E \overset{\mathrm{L}}{\otimes}_K \mathrm{RHom}_A(E, A \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_A F & \longrightarrow & M \overset{\mathrm{L}}{\otimes}_K F, \end{array}$$

where the horizontal arrows are given by the evaluations (5.3.6). This square is deduced, by applying $- \overset{\mathrm{L}}{\otimes}_B F$, from the analogous square with $F = B$, so that one may suppose $F = B$. The commutativity of 5.10.7 in this case is equivalent to that of the triangle

$$\begin{array}{ccc} \mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) & & \\ \downarrow{\scriptstyle (1)} & \searrow^{(2)} & \\ \mathrm{RHom}_B(E, \mathrm{Hom}_A(B, B \overset{\mathrm{L}}{\otimes}_K M)) & \xrightarrow[(3)]{} & \mathrm{RHom}_A(E, B \overset{\mathrm{L}}{\otimes}_K M), \end{array}$$

where (1) is defined by 5.10.1, (2) is restriction of scalars, and (3) is the adjunction isomorphism. But the arrow $B \overset{\mathrm{L}}{\otimes}_K M \to \mathrm{Hom}_A(B, B \overset{\mathrm{L}}{\otimes}_K M)$ given by 5.10.1 is nothing other than the adjunction arrow corresponding to the functors restriction of scalars and $\mathrm{Hom}_A(B, -)$; the commutativity follows at once.

Let $E \in \mathrm{ob}\, D^-(B)$, $M \in \mathrm{ob}\, D^b(K)$ be such that $\mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \in \mathrm{ob}\, D^b(B^\circ)$. Then, by 5.3.5, there is an evaluation arrow

$$\mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_{B^e} E \longrightarrow M \overset{\mathrm{L}}{\otimes}_K (B \overset{\mathrm{L}}{\otimes}_{B^e} B),$$

which, by composition with the canonical arrow $B \overset{\mathrm{L}}{\otimes}_{B^e} B \to B_\natural$, gives an arrow

$$\mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_B E \longrightarrow M \overset{\mathrm{L}}{\otimes}_K B_\natural. \tag{5.10.8}$$

Proposition 5.10.9. Suppose that A is of finite presentation and flat as a K-module, and that $A_\natural$, $B_\natural$ are flat over K. Let $E \in \operatorname{ob} D^-(B)$, $M \in \operatorname{ob} D^b(K)$ be such that $\mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \in \operatorname{ob} D^b(B^\circ)$. Then $\mathrm{RHom}_A(E, A \overset{\mathrm{L}}{\otimes}_K M) \in \operatorname{ob} D^b(A^\circ)$, and there is a commutative square

$$\begin{array}{ccc} \mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_B E & \xrightarrow{5.10.8} & M \overset{\mathrm{L}}{\otimes}_K B_\natural \\ \downarrow{\scriptstyle 5.10.5} & & \downarrow{\scriptstyle M\otimes_K \mathrm{Tr}_{B/A}} \\ \mathrm{RHom}_A(E, A \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_A E & \xrightarrow[5.10.8]{} & M \overset{\mathrm{L}}{\otimes}_K A_\natural. \end{array} \tag{5.10.10}$$

The additional hypotheses on A and B (verified, for example, if A and B are K-algebras of finite groups) are no doubt useless, and one should have a commutative square analogous to 5.10.10 with $A_\natural$ (resp. $B_\natural$) replaced by $A \overset{\mathrm{L}}{\otimes}_{A^e} A$ (resp. $B \overset{\mathrm{L}}{\otimes}_{B^e} B$).

The first assertion of 5.10.9 is trivial. We prove the second. We may suppose that M has injective components and that E has components of the form $B \otimes_K L$, with L flat. Then

$$\mathrm{RHom}_B(E, B \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_B E = \mathrm{Hom}_B^\bullet(E, B \otimes_K M) \otimes_B E,$$

$$\mathrm{RHom}_A(E, A \overset{\mathrm{L}}{\otimes}_K M) \overset{\mathrm{L}}{\otimes}_A E = \mathrm{Hom}_A^\bullet(E, A \otimes_K M) \otimes_A E,$$

and the arrows in 5.10.10 are defined at the level of complexes. Thus we are reduced to verifying that, if L, M are K-modules and E a left B-module, there is a commutative square

$$(*) \qquad \begin{array}{ccc} \mathrm{Hom}_B(B \otimes_K L, B \otimes_K M) \otimes_B (B \otimes_K L) & \xrightarrow{5.3.3} & M \otimes_K B_\natural \\ \downarrow{\scriptstyle (1)} & & \downarrow{\scriptstyle M\otimes_K \mathrm{Tr}_{B/A}} \\ \mathrm{Hom}_A(B \otimes_K L, A \otimes_K M) \otimes_A (B \otimes_K L) & \xrightarrow[5.3.3]{} & M \otimes_K A_\natural, \end{array}$$

where the arrow (1) is defined by sending $B \otimes_K M$ into $\mathrm{Hom}_A(B, A) \otimes_A B \otimes_K M$ by 5.10.1 and composing with an isomorphism of the type 5.10.3 and an adjunction isomorphism. Since A is flat and of finite presentation as a K-module, the "tensor-product" arrows

$$(2) \quad B \otimes_K \mathrm{Hom}_K(L, M) = \mathrm{Hom}_B(B, B) \otimes_K \mathrm{Hom}_K(L, M) \to \mathrm{Hom}_B(B \otimes_K L, B \otimes_K M),$$

$$(3) \quad \mathrm{Hom}_A(B, A) \otimes_K \mathrm{Hom}_K(L, M) \to \mathrm{Hom}_A(B \otimes_K L, A \otimes_K M)$$

are isomorphisms, by which (1) identifies with the tensor product (over K) of 5.10.1 by $\mathrm{Hom}_K(L, M) \otimes_K L$. On the other hand, the upper (resp. lower) horizontal arrow of (*) identifies by (2) (resp. (3)) with the tensor product (over K) of $\mathrm{Tr}_B : B \to B_\natural$ (resp. $\mathrm{ev} : \mathrm{Hom}_A(B, A) \otimes_A B \to A_\natural$) by the evaluation arrow $\mathrm{Hom}_K(L, M) \otimes_K L \to M$. The commutativity therefore follows from that of 5.10.2, completing the proof of 5.10.9.

Corollary 5.10.11. Under the hypotheses of 5.10.9, for $E \in \operatorname{ob} D(B)_{\mathrm{parf}}$, $M \in \operatorname{ob} D^b(K)$, there is

a commutative square in $D(K)$

$$\begin{array}{ccc} \mathrm{RHom}_B(E, M \overset{\mathrm{L}}{\otimes}_K E) & \xrightarrow{\mathrm{Tr}_B} & M \overset{\mathrm{L}}{\otimes}_K B_\natural \\ \downarrow & & \downarrow{\scriptstyle M \overset{\mathrm{L}}{\otimes} \mathrm{Tr}_{B/A}} \\ \mathrm{RHom}_A(E, M \overset{\mathrm{L}}{\otimes}_K E) & \xrightarrow[\mathrm{Tr}_A]{} & M \overset{\mathrm{L}}{\otimes}_K A_\natural, \end{array} \tag{5.10.12}$$

where the left vertical arrow is restriction of scalars.

It is enough indeed to conjugate 5.10.6 and 5.10.9.

5.11. Application to finite groups: divisibility properties

Let G be a finite group, with neutral element denoted e, and put $K[G] = B$. The K-module $B_\natural$ is free with basis the set $G_\natural$ of conjugacy classes of G; every section s of $B_\natural$ is written uniquely

$$s = \sum_{x \in G_\natural} s(x)x.$$

Proposition 5.11.1. Cf. SGA $4^{1/2}$, Rapport 4.5. Let $E \in \mathrm{ob}\, D(B)_{\mathrm{parf}}$, $M \in \mathrm{ob}\, D^b(K)$. For $u \in \mathrm{Hom}_B(E, M \overset{\mathrm{L}}{\otimes}_K E)$, one has, in $H^0(T, M)$,

$$\mathrm{Tr}_K(u) = |G|^{17}\ \mathrm{Tr}_B(u)(e). \tag{*}$$

It is enough to apply 5.10.11 with $A = K$, noting that $\mathrm{Tr}_{B/K} : B_\natural \to K$ is given by

$$\mathrm{Tr}_{B/K}(g) = \begin{cases} |G|, & g = e, \\ 0, & g \neq e. \end{cases} \tag{5.11.2}$$

Proposition 5.11.3. Under the hypotheses of 5.11.1, let $g \in G$, let Z_g be the centralizer of g in G, and put $A = K[Z_g]$. Let $u \in \mathrm{Hom}_B(E, M \overset{\mathrm{L}}{\otimes}_K E)$, and let $gu \in \mathrm{Hom}_A(E, M \overset{\mathrm{L}}{\otimes}_K E)$ be the composite of the image of u in $\mathrm{Hom}_A(E, M \overset{\mathrm{L}}{\otimes}_K E)$ with left multiplication by g. Then, in $H^0(T, M)$,

$$\mathrm{Tr}_A(gu)(e) = \mathrm{Tr}_B(u)(g^{-1}).$$

We shall show more generally that there is a commutative square

$$\begin{array}{ccccc} \mathrm{RHom}_B(E, M \overset{\mathrm{L}}{\otimes}_K E) & \xrightarrow{\mathrm{Tr}_B} & M \overset{\mathrm{L}}{\otimes}_K B_\natural & \xrightarrow{x \mapsto x(g^{-1})} & M \\ \downarrow & & & & \| \\ \mathrm{RHom}_A(E, M \overset{\mathrm{L}}{\otimes}_K E) & \xrightarrow[\mathrm{Tr}_A]{} & M \overset{\mathrm{L}}{\otimes}_K A_\natural & \xrightarrow[x \mapsto x(e)]{} & M, \end{array} \tag{5.11.4}$$

[17] If X is a set, $|X|$ denotes the cardinality of X.

where the left vertical arrow is the composite of restriction of scalars and left multiplication by g. This square is the boundary of the diagram

$$\begin{array}{ccccc}
\mathrm{RHom}_B(E, M \overset{\mathrm{L}}{\otimes}_K E) & \xrightarrow{\mathrm{Tr}_B} & M \overset{\mathrm{L}}{\otimes}_K B_\natural & \xrightarrow{x\mapsto x(g^{-1})} & M \\
\Big\downarrow{\scriptstyle \mathrm{rest}} & & \Big\downarrow{\scriptstyle \mathrm{Tr}_{B/A}}\ (1) & & \Big\| \\
\mathrm{RHom}_A(E, M \overset{\mathrm{L}}{\otimes}_K E) & \xrightarrow[\mathrm{Tr}_A]{} & M \overset{\mathrm{L}}{\otimes}_K A_\natural & & M \\
\Big\downarrow{\scriptstyle \mathrm{RHom}_A(E, s_g)} & & \Big\downarrow{\scriptstyle s_g}\ (2) & (3) & \\
\mathrm{RHom}_A(E, M \overset{\mathrm{L}}{\otimes}_K E) & \xrightarrow[\mathrm{Tr}_A]{} & M \overset{\mathrm{L}}{\otimes}_K A_\natural & \xrightarrow[x\mapsto x(e)]{} & M,
\end{array}$$

where rest denotes restriction of scalars and s_g left multiplication by g. Square (1) commutes by 5.10.11, and (2) by the definition of Tr_A. It therefore remains to prove the commutativity of (3), for which it is enough to show that, for $h \in G$,

$$\mathrm{Tr}_A(x \mapsto gxh)(e) = \text{the value at } g^{-1} \text{ of the image of } h \text{ in } B,$$

i.e.

$$\mathrm{Tr}_A(x \mapsto gxh)(e) = \begin{cases} 1, & g^{-1} \text{ is conjugate to } h, \\ 0, & \text{otherwise.} \end{cases} \tag{*}$$

For this one may replace T by the punctual topos and K by $\mathbb{Z}$, and it is then enough to prove (*) after multiplication by $|Z_g|$. In view of 5.11.1, we are therefore reduced to showing that

$$\mathrm{Tr}_{\mathbb{Z}}(x \mapsto gxh) = \begin{cases} |Z_g|, & g^{-1} \text{ is conjugate to } h, \\ 0, & \text{otherwise.} \end{cases}$$

But this follows from the fact that the left hand side is the number of fixed points of the map $x \mapsto gxh$ from G to G, whence the commutativity of 5.11.4 and the conclusion of 5.11.3.

Corollary 5.11.5. Under the hypotheses of 5.11.3, one has

$$\mathrm{Tr}_K(gu) = |Z_g|\ \mathrm{Tr}_B(u)(g^{-1}) = |Z_g|\ \mathrm{Tr}_A(gu)(e). \tag{5.11.5}$$

5.12. Traces and external tensor products

Let, for $i = 1, 2$, A_i be a flat K-algebra, and put $A = A_1 \otimes_K A_2$. Let $E_i \in \mathrm{ob}\, D^-(A_i)$, $F_i \in \mathrm{ob}\, D^b(A_i^e)$ be such that $\mathrm{RHom}_{A_i}(E_i, F_i) \in \mathrm{ob}\, D^b(A_i^\circ)$, let $F = F_1 \overset{\mathrm{L}}{\otimes}_K F_2 \in \mathrm{ob}\, D^b(A^e)$, and suppose $\mathrm{RHom}_A(E, F) \in \mathrm{ob}\, D^b(A^\circ)$, where $E = E_1 \overset{\mathrm{L}}{\otimes}_K E_2$. Then there is a commutative square

$$\begin{array}{ccc}
(\mathrm{RHom}_{A_1}(E_1, F_1) \overset{\mathrm{L}}{\otimes}_{A_1} E_1) \overset{\mathrm{L}}{\otimes}_K (\mathrm{RHom}_{A_2}(E_2, F_2) \overset{\mathrm{L}}{\otimes}_{A_2} E_2) & \xrightarrow{(1)} & (F_1 \overset{\mathrm{L}}{\otimes}_{A_1^e} A_1) \overset{\mathrm{L}}{\otimes}_K (F_2 \overset{\mathrm{L}}{\otimes}_{A_2^e} A_2) \\
\Big\downarrow{\scriptstyle (2)} & & \Big\downarrow{\scriptstyle (3)} \\
\mathrm{RHom}_A(E, F) \overset{\mathrm{L}}{\otimes}_A E & \longrightarrow & F \overset{\mathrm{L}}{\otimes}_{A^e} A,
\end{array} \tag{5.12.1}$$

where (1) is the tensor product of the arrows 5.3.5, (2) is defined by the tensor-product arrow

$$\mathrm{RHom}_{A_1}(E_1,F_1)\overset{\mathrm{L}}{\otimes}_K \mathrm{RHom}_{A_2}(E_2,F_2)\longrightarrow \mathrm{RHom}_A(E,F), \tag{5.12.2}$$

and (3) is the evident canonical isomorphism. The verification is essentially trivial. One checks in the same way that, for $E_i\in \mathrm{ob}\, D^-(A_i)$, $F_i\in \mathrm{ob}\, D^+(A_i^e)$, $G_i\in \mathrm{ob}\, D^-(A_i)$, with $F_i\overset{\mathrm{L}}{\otimes}_{A_i} G_i\in \mathrm{ob}\, D^b(A_i)$, $\mathrm{RHom}_{A_i}(E_i,F_i)\in \mathrm{ob}\, D^b(A_i^\circ)$, $\mathrm{RHom}_{A_i}(E_i,F_i\overset{\mathrm{L}}{\otimes}_{A_i} G_i)\in \mathrm{ob}\, D^b(K)$, $F\overset{\mathrm{L}}{\otimes}_A G\in \mathrm{ob}\, D^b(A)$, where $G=G_1\overset{\mathrm{L}}{\otimes}_K G_2$, there is a commutative square

$$\begin{array}{ccc}
\begin{array}{c}(\mathrm{RHom}_{A_1}(E_1,F_1)\overset{\mathrm{L}}{\otimes}_{A_1} G_1)\overset{\mathrm{L}}{\otimes}_K\\ (\mathrm{RHom}_{A_2}(E_2,F_2)\overset{\mathrm{L}}{\otimes}_{A_2} G_2)\end{array} & \xrightarrow{(1)} & \begin{array}{c}\mathrm{RHom}_{A_1}(E_1,F_1\overset{\mathrm{L}}{\otimes}_{A_1} G_1)\overset{\mathrm{L}}{\otimes}_K\\ \mathrm{RHom}_{A_2}(E_2,F_2\overset{\mathrm{L}}{\otimes}_{A_2} G_2)\end{array}\\
\downarrow{\scriptstyle (2)} & & \downarrow{\scriptstyle (3)}\\
\mathrm{RHom}_A(E,F)\overset{\mathrm{L}}{\otimes}_A G & \xrightarrow[5.4.2]{} & \mathrm{RHom}_A(E,F\overset{\mathrm{L}}{\otimes}_A G),
\end{array} \tag{5.12.3}$$

where (2) and (3) are tensor-product arrows of the type 5.12.2, and (1) is the tensor product of the arrows 5.4.2. From the commutativity of the squares 5.12.1 and 5.12.3 it follows that, for $E_i\in \mathrm{ob}\, D(A_i)_{\mathrm{parf}}$, $F_i\in \mathrm{ob}\, D^b(A_i^e)$ such that $F=F_1\overset{\mathrm{L}}{\otimes}_K F_2\in \mathrm{ob}\, D^b(A^e)$, there is a commutative square

$$\begin{array}{ccc}
\mathrm{RHom}_{A_1}(E_1,F_1\overset{\mathrm{L}}{\otimes}_{A_1} E_1)\overset{\mathrm{L}}{\otimes}_K \mathrm{RHom}_{A_2}(E_2,F_2\overset{\mathrm{L}}{\otimes}_{A_2} E_2) & \xrightarrow{(1)} & (F_1\overset{\mathrm{L}}{\otimes}_{A_1^e} A_1)\overset{\mathrm{L}}{\otimes}_K (F_2\overset{\mathrm{L}}{\otimes}_{A_2^e} A_2)\\
\downarrow{\scriptstyle (2)} & & \downarrow{\scriptstyle (3)}\\
\mathrm{RHom}_A(E,F\overset{\mathrm{L}}{\otimes}_A E) & \xrightarrow[5.6.1]{} & F\overset{\mathrm{L}}{\otimes}_{A^e} A,
\end{array} \tag{5.12.4}$$

where (1) is the tensor product of the arrows Tr_{A_i} (5.6.1), (2) is defined by 5.12.2, and (3) is the canonical isomorphism appearing in 5.12.1. Consequently, for $u_i\in \mathrm{Hom}_{A_i}(E_i,F_i\overset{\mathrm{L}}{\otimes}_{A_i} E_i)$, one has

$$\mathrm{Tr}_A(u_1\overset{\mathrm{L}}{\otimes}_K u_2)=\mathrm{Tr}_{A_1}(u_1)\,\mathrm{Tr}_{A_2}(u_2), \tag{5.12.5}$$

the product on the right being defined by the canonical arrow

$$H^0(T,F_1\overset{\mathrm{L}}{\otimes}_{A_1^e} A_1)\otimes H^0(T,F_2\overset{\mathrm{L}}{\otimes}_{A_2^e} A_2)\longrightarrow H^0(T,F\overset{\mathrm{L}}{\otimes}_{A^e} A).$$

5.13. Traces of semilinear endomorphisms

Let A be a K-algebra and φ an endomorphism of A. If E, F are left A-modules, recall that an additive homomorphism $u:E\to F$ is called φ-A-linear if $u(ax)=\varphi(a)u(x)$ for all $a\in A$, $x\in E$, i.e. if u is an A-linear homomorphism from E to the A-module ${}_{(\varphi)}F$ deduced from F by restriction of scalars along φ. If F is an A-bimodule and G a left A-module, there is an evident isomorphism

$${}_{(\varphi)}F\otimes_A G\xrightarrow{\sim}{}_{(\varphi)}(F\otimes_A G),$$

which derives trivially to

$${}_{(\varphi)}F\overset{\mathrm{L}}{\otimes}_A G\xrightarrow{\sim}{}_{(\varphi)}(F\overset{\mathrm{L}}{\otimes}_A G).$$

Assuming A flat over K, one deduces from 5.4.2 the arrow

$$\mathrm{RHom}_A(E, {}_{(\varphi)}F) \overset{\mathrm{L}}{\otimes}_A G \longrightarrow \mathrm{RHom}_A(E, {}_{(\varphi)}(F \overset{\mathrm{L}}{\otimes}_A G)) \tag{5.13.1}$$

for $E \in \mathrm{ob}\, D^-(A)$, $F \in \mathrm{ob}\, D^+(A^e)$, $G \in \mathrm{ob}\, D^-(A)$, with $F \overset{\mathrm{L}}{\otimes}_A G \in \mathrm{ob}\, D^+(A)$. For $E \in \mathrm{ob}\, D(A)_{\mathrm{parf}}$, 5.13.1 is an isomorphism, which allows one to define, by 5.3.5, a trace arrow

$$\mathrm{Tr}_{A,\varphi} : \mathrm{RHom}_A(E, {}_{(\varphi)}(F \overset{\mathrm{L}}{\otimes}_A E)) \longrightarrow {}_{(\varphi)}F \overset{\mathrm{L}}{\otimes}_{A^e} A. \tag{5.13.2}$$

In particular, for $F = A$, one obtains

$$\mathrm{Tr}_{A,\varphi} : \mathrm{Hom}_A(E, {}_{(\varphi)}E) \longrightarrow H^0(T, A_{\natural,\varphi}), \tag{5.13.3}$$

where $A_{\natural,\varphi} = {}_{(\varphi)}A \otimes_{A^e} A$ is the quotient K-module of A by the submodule locally generated by local sections of the form $ab - \varphi(b)a$. In the case where $A = K[G]$, G is a discrete group, and φ is defined by an endomorphism φ of G, $A_{\natural,\varphi}$ is the free K-module with basis $G_{\natural,\varphi}$, where $G_{\natural,\varphi}$ is the quotient of G by the action $(g, x) \mapsto \varphi(g)xg^{-1}$; the orbits are sometimes called φ-conjugacy classes of G. The traces 5.13.2 coincide, for T punctual, with those considered by Grothendieck and discussed in Exposé XII.

In the situation of 5.10, if φ, ψ are respective endomorphisms of A, B, compatible with $A \to B$, there is a unique arrow

$$\mathrm{Tr}_A : B_{\natural,\psi} \longrightarrow A_{\natural,\varphi}$$

making the square, analogous to 5.10.2,

$$\begin{array}{ccc} {}_{(\psi)}B = \mathrm{Hom}_B(B, {}_{(\psi)}B) & \xrightarrow{\mathrm{Tr}_{B,\psi}} & B_{\natural,\psi} \\ \downarrow & & \downarrow{\scriptstyle \mathrm{Tr}_A} \\ \mathrm{Hom}_A(B, {}_{(\varphi)}A) \otimes_A B & \xrightarrow[\mathrm{ev}]{} & A_{\natural,\varphi}, \end{array} \tag{5.13.4}$$

commute, where ev is the evaluation arrow, and the left vertical arrow is restriction of scalars. One defines an arrow analogous to 5.10.5, with $A \otimes_K M$ (resp. $B \otimes_K M$) replaced by ${}_{(\varphi)}A \otimes_K M$ (resp. ${}_{(\psi)}B \otimes_K M$), and there are compatibilities analogous to 5.10.6, 5.10.9, 5.10.11, which we leave to the reader to state.

Let G be a finite group and φ an endomorphism of G. For $g \in G$, let $Z_{g,\varphi}$ be the φ-centralizer of g in G, i.e. the set of $x \in G$ such that $\varphi(x)gx^{-1} = g$. Put $A = K[G]$, and let $E \in \mathrm{ob}\, D(A)_{\mathrm{parf}}$, $M \in \mathrm{ob}\, D^b(K)$. The preceding compatibilities easily imply that, for $u \in \mathrm{Hom}_A(E, {}_{(\varphi)}(M \overset{\mathrm{L}}{\otimes}_K E))$ and $g \in G$,

$$\mathrm{Tr}_K(gu) = |Z_{g^{-1},\varphi}|\ \mathrm{Tr}_{A,\varphi}(u)(g^{-1}), \tag{5.13.5}$$

the details of the verification being left to the reader.

6. Equivariant Correspondences and Divisibility of Local Terms

6.1. Notation

In this number, S denotes the spectrum of a field of characteristic p, and Λ a noetherian commutative ring annihilated by an integer not divisible by p. The S-schemes considered will be assumed separated

and of finite type. The Λ-algebras considered will be associative, unital, and of finite type, but not necessarily commutative. Most often, and in particular for everything concerning "non-commutative Lefschetz–Verdier local terms," they will be assumed flat; in applications, they will be algebras of finite groups.

If X is an S-scheme and A a Λ-algebra, we write $D({}_AX)$ (resp. $D(X_A)$) for the derived category of the category of sheaves of left (resp. right) A-modules on X. For A commutative, we shall also write $D(X, A)$ for $D({}_AX)$, and $D(X) = D(X, \Lambda)$. We denote by $D_c(-)$ (resp. $D_{\mathrm{ctf}}(-)$) the full subcategory formed by complexes with constructible cohomology (resp. finite tor-dimension and constructible cohomology). If A, B are Λ-algebras, we write $D({}_AX_B)$ for the derived category of sheaves of (A, B)-bimodules, left over A and right over B. Finally, we use the notations A^o, A^e, $A_\natural$ of 5.1.

6.2

The formalism of (III 1, 2, 3) extends without difficulty to the "non-commutative" case. We briefly indicate the main points of this generalization.

Let X be an S-scheme and let A, B be Λ-algebras. If $L \in \mathrm{ob}\, D_{\mathrm{ctf}}(X_A)$ and $M \in \mathrm{ob}\, D({}_AX_B)$, with M of finite tor-dimension and constructible cohomology as an object of $D(X_B)$, then

$$L \overset{\mathrm{L}}{\otimes}_A M \in \mathrm{ob}\, D(X_B)_{\mathrm{ctf}}$$

as is immediate. On the other hand, it follows from (SGA $4^{1/2}$ Finiteness 1.6) that, for M as above and $L \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_AX)$, one has

$$\mathrm{RHom}_A(L, M) \in \mathrm{ob}\, D_{\mathrm{ctf}}(X_B).$$

It also follows from loc. cit. that, if f is an S-morphism, $D_{\mathrm{ctf}}({}_A-)$ is stable under the operations $(f^*, f_*, f_!, f^!)$, the case of f^* being trivial.

Let, for $i = 1, 2$, $f_i : X_i \to Y_i$ be an S-morphism,

$$f = f_1 \times_S f_2 : X = X_1 \times_S X_2 \longrightarrow Y = Y_1 \times_S Y_2,$$

and let A be a Λ-algebra. For $L_1 \in \mathrm{ob}\, D^-(X_{1A})$, $L_2 \in \mathrm{ob}\, D^-({}_AX_2)$, there is a Künneth arrow in $D^-(Y)$

$$f_{1!}L_1 \overset{\mathrm{L}}{\otimes}_{S,A} f_{2!}L_2 \longrightarrow f_*(L_1 \overset{\mathrm{L}}{\otimes}_{S,A} L_2), \tag{6.2.1}$$

where

$$L_1 \overset{\mathrm{L}}{\otimes}_{S,A} L_2 \overset{\mathrm{dfn}}{=} p_1^*L_1 \overset{\mathrm{L}}{\otimes}_A p_2^*L_2.$$

As in (III 1.6), one deduces that it is an isomorphism. If B, C are Λ-algebras, with B or C assumed flat over Λ in order to define

$$\overset{\mathrm{L}}{\otimes}_A : D^-({}_B-_A) \times D^-({}_A-_C) \longrightarrow D^-({}_B-_C),$$

there is an isomorphism analogous to 6.2.1 in $D^-({}_BY_C)$, for $L_1 \in \mathrm{ob}\, D^-({}_BX_{1A})$, $L_2 \in \mathrm{ob}\, D^-({}_AX_{2B})$. One checks similarly that, for $M_1 \in \mathrm{ob}\, D^-(Y_{1A})$, $M_2 \in \mathrm{ob}\, D^-({}_AY_2)$, there is a Künneth isomorphism in $D^-(X)$

$$f^!M_1 \overset{\mathrm{L}}{\otimes}_{S,A} f^!M_2 \longrightarrow f^!(M_1 \overset{\mathrm{L}}{\otimes}_{S,A} M_2), \tag{6.2.2}$$

and an analogous isomorphism in $D^-({}_BX_C)$ for $M_1 \in \mathrm{ob}\, D^-({}_BY_{1A})$, $M_2 \in \mathrm{ob}\, D^-({}_AY_{2C})$.

Finally, let, for $i = 1, 2$, A_i be a Λ-algebra, A_2 being flat, $E_1 \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{A_1}X_1)$, $F_2 \in \mathrm{ob}\, D^+({}_{A_2}X_2)$, $F_1 \in \mathrm{ob}\, D({}_{A_1}X_{1A_2})$, with F_1 of finite tor-dimension and constructible cohomology as an object of $D(X_{1A_2})$. Then

$$\mathrm{RHom}_{A_1}(E_1, F_1) \in \mathrm{ob}\, D_{\mathrm{ctf}}(X_{1A_2}),$$

as seen above, and there is a canonical arrow in $D^+(X)$ ($D^+(X, A_2)$ when A_2 is commutative)

$$\mathrm{RHom}_{A_1}(E_1, F_1) \overset{\mathrm{L}}{\otimes}_{S,A_2} F_2 \longrightarrow \mathrm{RHom}_{A_1}(p_1^*E_1, F_1 \overset{\mathrm{L}}{\otimes}_{S,A_2} F_2), \tag{6.2.3}$$

defined by composing the "inverse-image" arrow (III 2.1.1)

$$p_1^*\mathrm{RHom}_{A_1}(E_1, F_1) \overset{\mathrm{L}}{\otimes}_{A_2} p_2^*F_2 \longrightarrow \mathrm{RHom}_{A_1}(p_1^*E_1, p_1^*F_1) \overset{\mathrm{L}}{\otimes}_{A_2} p_2^*F_2$$

with the arrow analogous to 5.4.2

$$\mathrm{RHom}_{A_1}(p_1^*E_1, p_1^*F_1) \overset{\mathrm{L}}{\otimes}_{A_2} p_2^*F_2 \longrightarrow \mathrm{RHom}_{A_1}(p_1^*E_1, p_1^*F_1 \overset{\mathrm{L}}{\otimes}_{A_2} p_2^*F_2),$$

adjoint, by 5.2.3, to the arrow

$$p_1^*E_1 \overset{\mathrm{L}}{\otimes} \mathrm{RHom}_{A_1}(p_1^*E_1, p_1^*F_1) \overset{\mathrm{L}}{\otimes}_{A_2} p_2^*F_2 \longrightarrow p_1^*F_1 \overset{\mathrm{L}}{\otimes}_{A_2} p_2^*F_2$$

defined by the evaluation arrow 5.3.6. One deduces from 6.2.1, as in (III 2.3), that 6.2.3 is an isomorphism. In particular, for $A_2 = \Lambda$, $F_2 = \Lambda_{X_2}$, 6.2.3 gives an isomorphism

$$p_1^*\mathrm{RHom}_{A_1}(E_1, F_1) \xrightarrow{\sim} \mathrm{RHom}_{A_1}(p_1^*E_1, p_1^*F_1). \tag{6.2.4}$$

6.3

If $t : T \to S$ is an S-scheme, and A is a Λ-algebra, we put

$$t^!_A = KA_T \qquad (\in \mathrm{ob}\, D^+({}_AT_A)). \tag{6.3.1}$$

For $A = \Lambda$, we write K_T instead of $K\Lambda_T$. It follows from 6.2.2 that there is a canonical isomorphism in $D^+({}_AT_A)$

$$K_T \overset{\mathrm{L}}{\otimes} A \xrightarrow{\sim} KA_T. \tag{6.3.2}$$

We denote by D_A the functor

$$\mathrm{RHom}_A(-, KA_T).$$

It sends $D_{\mathrm{ctf}}({}_AT)$ into $D_{\mathrm{ctf}}(T_A)$ and conversely, and the proof of (SGA $4^{1/2}$ Finiteness Theorem 4) shows that, for $L \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_AT)$, the canonical arrow

$$L \longrightarrow D_AD_AL$$

is an isomorphism. For $A = \Lambda$, we write D instead of D_A.

6.4

Let A be a flat Λ-algebra, and let, for $i = 1, 2$, X_i be an S-scheme, $X = X_1 \times_S X_2$, $p_i : X \to X_i$ the projections, and $L_i \in \operatorname{ob} D_{\mathrm{ctf}}({}_A X_i)$. By 6.2.3 applied to $A_1 = A_2 = A$, $E_1 = L_1$, $F_2 = L_2$, $E_2 = KA_{X_1}$, there is an isomorphism

$$D_A L_1 \overset{\mathrm{L}}{\otimes}_{S,A} L_2 \xrightarrow{\sim} \mathrm{RHom}_A(p_1^* L_1, KA_{X_1} \overset{\mathrm{L}}{\otimes}_{S,A} L_2),$$

whence, by composing with the Künneth isomorphism 6.2.2

$$KA_{X_1} \overset{\mathrm{L}}{\otimes}_{S,A} L_2 \xrightarrow{\sim} p_2^! L_2,$$

an isomorphism

$$D_A L_1 \overset{\mathrm{L}}{\otimes}_{S,A} L_2 \xrightarrow{\sim} \mathrm{RHom}_A(p_1^* L_1, p_2^! L_2), \tag{6.4.1}$$

which generalizes (III 3.1.1).

Let $c : C \to X$ be an S-morphism, and put $c_i = p_i c$. By the induction formula (SGA 4 XVIII 3.1.12.2), there is a canonical isomorphism, analogous to (III 3.2.1),

$$c^! \mathrm{RHom}_A(p_1^* L_1, p_2^! L_2) \xrightarrow{\sim} \mathrm{RHom}_A(c_1^* L_1, c_2^! L_2), \tag{6.4.2}$$

and hence, by composing with 6.4.1, an isomorphism

$$H^0(X, c_* c^!(D_A L_1 \overset{\mathrm{L}}{\otimes}_{S,A} L_2)) \xrightarrow{\sim} \mathrm{Hom}_A(c_1^* L_1, c_2^! L_2). \tag{6.4.3}$$

The elements of $\mathrm{Hom}_A(c_1^* L_1, c_2^! L_2)$ will be called cohomological correspondences from L_1 to L_2 with support in c. The terminology differs slightly from that of loc. cit.; the two terminologies coincide when c is proper, which is the case in practice.

Given S-morphisms $f_i : X_i \to Y_i$ $(i = 1, 2)$ and a commutative square (III 3.7.1) with c proper, one defines, as in loc. cit., direct-image arrows analogous to (III 3.7.5), (III 3.7.6), for $L_i \in \operatorname{ob} D_{\mathrm{ctf}}({}_A X_i)$.

6.5

Let A be a flat Λ-algebra, X an S-scheme, $X^2 = X \times_S X$, $p_1, p_2 : X^2 \to X$ the canonical projections, $\delta : X \to X^2$ the diagonal, and

$$c : C \longrightarrow X^2$$

an S-morphism. Put $c_i = p_i c$, and let $X^c = C \times_{X^2} X$ be the scheme of fixed points of c, giving a cartesian square

$$\begin{array}{ccc} X^c & \xrightarrow{i^c} & X \\ {\scriptstyle \delta^c}\downarrow & & \downarrow{\scriptstyle \delta} \\ C & \xrightarrow[c]{} & X^2. \end{array} \tag{6.5.1}$$

Put

$$KA_{X,L_\natural} = K_X \overset{\mathrm{L}}{\otimes}_\Lambda (A \overset{\mathrm{L}}{\otimes}_{A^e} A), \qquad KA_{X,\natural} = K_X \overset{\mathrm{L}}{\otimes}_\Lambda A_\natural. \tag{6.5.2}$$

Let $L \in \operatorname{ob} D_{\mathrm{ctf}}({}_A X)$. We define a "local trace" homomorphism

$$\mathrm{Tr}_A : \delta^* \mathrm{RHom}_A(p_1^* L, p_2^! L) \longrightarrow KA_{X,L_\natural}, \tag{6.5.3}$$

by composing the isomorphism

$$\delta^*\mathrm{RHom}_A(p_1^*L, p_2^!L) \xrightarrow{\sim} \delta^*(D_AL \overset{\mathrm{L}}{\otimes}_{S,A} L) \tag{6.5.4}$$

deduced from the inverse of 6.4.1 by applying δ^*, the trivial isomorphism

$$\delta^*(D_AL \overset{\mathrm{L}}{\otimes}_{S,A} L) = D_AL \overset{\mathrm{L}}{\otimes}_A L, \tag{6.5.5}$$

and the evaluation arrow 5.3.5

$$D_AL \overset{\mathrm{L}}{\otimes}_A L \longrightarrow KA_{X,L_\natural}. \tag{6.5.6}$$

(Here $KA_X \overset{\mathrm{L}}{\otimes}_{A^e} A$ is identified with $KA_{X,L_\natural}$ by means of 6.3.2, $K_X \otimes A = KA_X$.) It follows at once from the definition that, for $X = S$, 6.5.3 coincides with the arrow

$$\mathrm{Tr}_A : \mathrm{RHom}_A(L, L) \longrightarrow A \overset{\mathrm{L}}{\otimes}_{A^e} A$$

of 5.6.1. Composing the arrow deduced from 6.5.3 by applying $i^c c^!$ with the arrow

$$\delta^* c^c_* \mathrm{RHom}_A(c_1^*L, c_2^!L) \longrightarrow i^c_* i^{c!} \delta^* \mathrm{RHom}_A(p_1^*L, p_2^!L) \tag{6.5.7}$$

deduced from 6.4.2 and the base-change arrow

$$\delta^* c_* c^! \longrightarrow i^c_* i^{c!} \delta^*,$$

one obtains an arrow

$$\mathrm{Tr}_A : \delta^* c_* \mathrm{RHom}_A(c_1^*L, c_2^!L) \longrightarrow i^c_* i^{c!} KA_{X,L_\natural} = i^c_* KA_{X^c,L_\natural}, \tag{6.5.8}$$

and hence the arrow

$$\mathrm{Tr}_A : \mathrm{Hom}_A(c_1^*L, c_2^!L) \longrightarrow H^0(X^c, KA_{X^c,L_\natural}). \tag{6.5.9}$$

We again write Tr_A for the composites of 6.5.3, 6.5.8, 6.5.9 with the arrows deduced from the canonical arrow

$$KA_{X,L_\natural} \longrightarrow KA_{X,\natural}.$$

One checks easily that, for $A = \Lambda$, one has, for $u \in \mathrm{Hom}(c_1^*L, c_2^!L)$,

$$\mathrm{Tr}(u) = \langle u, 1 \rangle, \tag{6.5.10}$$

with the notation of (III 4.2.5), where 1 denotes the diagonal correspondence. More precisely, the arrow

$$c_* \mathrm{RHom}(c_1^*L, c_2^!L) \longrightarrow \delta_* i^c_* K_{X^c}$$

adjoint to 6.5.8 is the one defined by (III 4.2.4') with $X_1 = X_2$, $L_1 = L_2$, $d = \delta$, and the diagonal correspondence $1 \in \mathrm{Hom}(L, L)$.

6.6

Let A be a flat Λ-algebra, and let, for $i = 1, 2$, X_i be an S-scheme, $X = X_1 \times_S X_2$, and $L_i \in \operatorname{ob} D_{\mathrm{ctf}}({}_A X_i)$. We define a pairing

$$\mathrm{RHom}_A(p_1^* L_1, p_2^! L_2) \overset{\mathrm{L}}{\otimes}_\Lambda \mathrm{RHom}_A(p_2^* L_2, p_1^! L_1) \longrightarrow KA_{X, L_\natural} \tag{6.6.1}$$

as follows. One identifies the left hand side with

$$\mathrm{RHom}_A(p_1^* L_1, p_1^* KA_{X_1}) \overset{\mathrm{L}}{\otimes}_A p_2^* L_2 \overset{\mathrm{L}}{\otimes}_\Lambda \mathrm{RHom}_A(p_2^* L_2, p_2^* KA_{X_2}) \overset{\mathrm{L}}{\otimes}_A p_1^* L_1$$

by the isomorphisms 6.4.1, then with

$$A \overset{\mathrm{L}}{\otimes}_{A^e} \mathrm{RHom}_A(\ ) \overset{\mathrm{L}}{\otimes}_\Lambda p_2^* L_2 \overset{\mathrm{L}}{\otimes}_\Lambda \mathrm{RHom}_A(\ ) \overset{\mathrm{L}}{\otimes}_\Lambda p_1^* L_1 \overset{\mathrm{L}}{\otimes}_{A^e} A$$

by 5.3.1. This object is sent to

$$A \overset{\mathrm{L}}{\otimes}_{A^e} (KA_{X_1} \overset{\mathrm{L}}{\otimes}_\Lambda KA_{X_2}) \overset{\mathrm{L}}{\otimes}_{A^e} A = R$$

by the tensor product of the evaluation arrows 5.3.6. Finally R is identified with

$$A \overset{\mathrm{L}}{\otimes}_{A^e} (KA_{X_1} \overset{\mathrm{L}}{\otimes}_A KA_{X_2})$$

by 5.8.2, and then with $KA_{X, L_\natural}$ by 6.5.2 and (III 1.7.6).

If $c : C \to X$, $d : D \to X$ are correspondences, and

$$e = c \times_X d : E \to X,$$

one deduces from 6.6.1, as in (III 4.2), a pairing

$$c_* \mathrm{RHom}_A(c_1^* L_1, c_2^! L_2) \overset{\mathrm{L}}{\otimes}_\Lambda d_* \mathrm{RHom}_A(d_2^* L_2, d_1^! L_1) \longrightarrow e_* KA_{E, L_\natural}, \tag{6.6.2}$$

and hence a cup-product

$$\langle\ ,\ \rangle_A : \mathrm{Hom}_A(c_1^* L_1, c_2^! L_2) \otimes \mathrm{Hom}_A(d_2^* L_2, d_1^! L_1) \longrightarrow H^0(E, KA_{E, L_\natural}). \tag{6.6.3}$$

It is not difficult to extend to the non-commutative case the notion of composition of correspondences studied in (III 5.2), and one checks that, for

$$u \in \mathrm{Hom}_A(c_1^* L_1, c_2^! L_2), \qquad v \in \mathrm{Hom}_A(d_2^* L_2, d_1^! L_1),$$

one has the formula analogous to (III 5.2.9)

$$\langle u, v \rangle_A = \mathrm{Tr}_A(\bar{v} u) = \mathrm{Tr}_A(u \bar{v}). \tag{6.6.4}$$

The Lefschetz formula (III 4.4) generalizes without difficulty in this context. Given proper S-morphisms $f_i : X_i \to Y_i$ $(i = 1, 2)$ and a commutative cube (III 4.4.0), for $L_i \in \operatorname{ob} D_{\mathrm{ctf}}({}_A X_i)$ one has a commutative square analogous to (III 4.4.1), with K_C (resp. K_D) replaced by $KA_{C, L_\natural}$ (resp. $KA_{D, L_\natural}$), and a formula analogous to (III 4.5.1), in $H^0(D, KA_{D, L_\natural})$:

$$\langle f_* u, f_* v \rangle_A = g_* \langle u, v \rangle_A. \tag{6.6.5}$$

The arrow

$$f_* c_* KA_{C, L_\natural} \longrightarrow d_* KA_{D, L_\natural}$$

is deduced from arrow (4) of (III 4.4.1) by tensoring with

$$A \overset{\mathrm{L}}{\otimes}_{A^e} A.$$

6.7

Let X and c be as in 6.5, and let $A \to B$ be a morphism of flat Λ-algebras. With respect to extension and restriction of scalars, the arrows Tr_A (6.5.3, 6.5.8, 6.5.9) behave like the arrows Tr_A of 5.6.1, 5.6.2. The point is that, if f is an S-morphism, the functors $(f^*, f_*, f_!, f^!)$ commute with extension and restriction of scalars; consequently, the study of the behavior of Tr_A (6.5.3) with respect to extension and restriction of scalars reduces to the behavior of the "tensor-product" arrow

$$\mathrm{RHom}_A(p_1^*L, p_1^*KA_X) \overset{\mathrm{L}}{\otimes}_A p_2^*L \longrightarrow \mathrm{RHom}_A(p_1^*L, p_1^*KA_X \overset{\mathrm{L}}{\otimes}_A p_2^*L)$$

and of the "evaluation" arrow

$$\mathrm{RHom}_A(L, KA_X) \overset{\mathrm{L}}{\otimes}_A L \longrightarrow KA_{X,L_\natural}.$$

Thus the commutativity of the squares 5.9.1, 5.9.2 implies the commutativity of the square

$$\begin{array}{ccc} \delta^* c_* \mathrm{RHom}_A(c_1^*L, c_2^!L) & \xrightarrow{\mathrm{Tr}_A} & i_*^c KA_{X^c,L_\natural} \\ \downarrow & & \downarrow \\ \delta^* c_* \mathrm{RHom}_B(c_1^*(B \overset{\mathrm{L}}{\otimes}_A L), c_2^!(B \overset{\mathrm{L}}{\otimes}_A L)) & \xrightarrow[\mathrm{Tr}_B]{} & i_*^c KB_{X^c,L_\natural}, \end{array} \tag{6.7.1}$$

where the left vertical arrow is extension of scalars and the right vertical arrow is defined by the canonical arrow

$$A \overset{\mathrm{L}}{\otimes}_{A^e} A \longrightarrow B \overset{\mathrm{L}}{\otimes}_{B^e} B.$$

It follows that, for $u \in \mathrm{Hom}_A(c_1^*L, c_2^!L)$,

$$\mathrm{Tr}_B(B \overset{\mathrm{L}}{\otimes}_A u) = \varphi\, \mathrm{Tr}_A(u), \tag{6.7.2}$$

where

$$\varphi : H^0(X^c, KA_{X^c,L_\natural}) \longrightarrow H^0(X^c, KB_{X^c,L_\natural})$$

is the canonical map.

Assume A is finite type and flat as a Λ-module, B finite type and flat as a left A-module, and $A_\natural$, $B_\natural$ flat over Λ. There is a map $\mathrm{Tr}_{B/A} : B_\natural \to A_\natural$; we shall again denote by

$$\mathrm{Tr}_{B/A} : KB_{X,\natural} \longrightarrow KA_{X,\natural} \tag{6.7.3}$$

the arrow deduced from it by applying $K_X \overset{\mathrm{L}}{\otimes} -$ (6.5.2). It follows from 5.10.6 and 5.10.9 that, for $L \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_BX)$, there is a commutative square

$$\begin{array}{ccc} \delta^* c_* \mathrm{RHom}_B(c_1^*L, c_2^!L) & \xrightarrow{\mathrm{Tr}_B} & i_*^c KB_{X^c,\natural} \\ \downarrow & & \downarrow{\scriptstyle \mathrm{Tr}_{B/A}} \\ \delta^* c_* \mathrm{RHom}_A(c_1^*L, c_2^!L) & \xrightarrow[\mathrm{Tr}_A]{} & i_*^c KA_{X^c,\natural}, \end{array} \tag{6.7.4}$$

where the left vertical arrow is restriction of scalars. Consequently, for $u \in \mathrm{Hom}_B(c_1^*L, c_2^!L)$, one has, in $H^0(X^c, KA_{X^c,\natural})$,

$$\mathrm{Tr}_A(u) = \mathrm{Tr}_{B/A}(\mathrm{Tr}_B(u)). \tag{6.7.5}$$

6.8

Let A, B be flat Λ-algebras, X, Y S-schemes, $Z = X \times_S Y$, and let $c : C \to X^2$, $d : D \to Y^2$ be correspondences. Let

$$e = c \times_S d : E = C \times_S D \longrightarrow Z^2$$

be their product. Then

$$Z^e = X^c \times_S Y^d.$$

Put $R = A \otimes_\Lambda B$. As in (III 5.3), one defines the external tensor product

$$\mathrm{Hom}_A(c_1^* L, c_2^! L) \otimes \mathrm{Hom}_B(d_1^* M, d_2^! M) \xrightarrow{\overset{\mathrm{L}}{\otimes}_S} \mathrm{Hom}_R(e_1^*(L \overset{\mathrm{L}}{\otimes}_S M), e_2^!(L \overset{\mathrm{L}}{\otimes}_S M)), \tag{6.8.1}$$

and one deduces easily from the commutativity of the squares 5.12.1, 5.12.3 that, for

$$u \in \mathrm{Hom}_A(c_1^* L, c_2^! L), \qquad v \in \mathrm{Hom}_B(d_1^* M, d_2^! M),$$

one has, in $H^0(Z^e, KR_{Z^e, L_\natural})$,

$$\mathrm{Tr}_R(u \overset{\mathrm{L}}{\otimes}_S v) = \mathrm{Tr}_A(u)\,\mathrm{Tr}_B(v), \tag{6.8.2}$$

the product on the right being defined by the canonical arrow

$$H^0(X^c, KA_{X^c, L_\natural}) \otimes H^0(Y^d, KB_{Y^d, L_\natural}) \longrightarrow H^0(Z^e, KR_{Z^e, L_\natural}), \tag{6.8.3}$$

coming from the isomorphism

$$KA_{X^c, L_\natural} \overset{\mathrm{L}}{\otimes}_S KB_{Y^d, L_\natural} \longrightarrow K(A \otimes B)_{Z^e, L_\natural}$$

given by (III 1.7.6) and arrow (4) of 5.9.1.

6.9

Let G be a finite group. If X is a G-S-scheme, that is, an S-scheme endowed with an action of G by S-automorphisms,[18] and A is a Λ-algebra,[19] we denote by $D(G, {}_A X)$ the derived category of the category of sheaves of left G-A-modules on X. For the notions of G-sheaf of sets, rings, modules, and so on, on X for the étale topology, we refer the reader to (X 1). We denote by the subscript c (resp. ctf) the full subcategory formed by complexes of G-A-modules which, as complexes of A-modules, have constructible cohomology (resp. finite tor-dimension and constructible cohomology).

Similarly, if B is a Λ-algebra, we denote by $D(G, {}_A X_B)$ the derived category of sheaves of G-(A, B)-bimodules on X. If G acts trivially on X, a left G-A-module on X is just a left $A[G]$-module on X without operators, hence

$$D(G, {}_A X) = D({}_{A[G]} X).$$

Since G is finite, one also has

$$D_c({}_A X) = D_c({}_{A[G]} X),$$

but only an inclusion

$$D_{\mathrm{ctf}}({}_{A[G]} X) \subset D_{\mathrm{ctf}}(G, {}_A X).$$

[18] We agree that G acts on spaces on the right.

[19] We are chiefly interested in the case of commutative Λ-algebras.

The duality formalism of (SGA 4 XVII, XVIII) extends without difficulty to G-S-schemes. Since the functor forgetting the action of G is faithful, it is enough to extend naturally the definition of the "six operations" $(\overset{\mathrm{L}}{\otimes}, \mathrm{RHom}, f^*, f_*, f_!, f^!)$ and the canonical arrows considered in loc. cit. (base change, Künneth, duality, etc.). This extension presents no difficulty: for the definition of the functors $f_!$, $f^!$, it is enough to use equivariant compactifications. We leave to the reader the task of paraphrasing the definitions and results 6.2 to 6.8 in the setting of G-S-schemes.

If, for $i = 1, 2$, X_i is a G-S-scheme, $c : C \to X = X_1 \times_S X_2$ is a G-S-morphism, and $L_i \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{G,A}X_i)$, the elements of

$$\mathrm{Hom}_A(c_1^* L_1, c_2^! L_2),$$

where Hom_A is taken in the category $D({}_{G,A}-)$, will be called equivariant cohomological correspondences from L_1 to L_2 with support in c. Note that, when G acts trivially on X_i $(i = 1, 2)$ and $L_i \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{A[G]}X_i)$, the isomorphism 6.4.1 in $D(G, X)$ refines to an isomorphism

$$D_{A[G]} L_1 \overset{\mathrm{L}}{\otimes}_{S,A[G]} L_2 \xrightarrow{\sim} \mathrm{RHom}_{A[G]}(p_1^* L_1, p_2^! L_2).$$

It follows that, in a G-equivariant situation of type 6.5, with trivial action of G on the spaces, and with $L \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{A[G]}X) \subset D_{\mathrm{ctf}}({}_{G,A}X)$, one may, for

$$u \in \mathrm{Hom}_{A[G]}(c_1^* L, c_2^! L),$$

define a local term

$$\mathrm{Tr}_{A[G]}(u) \in H^0(X^c, KA[G]_{X^c, L_\natural}),$$

finer, in the evident sense, than the local term

$$\mathrm{Tr}_A(u) \in H^0(G, X^c, KA_{X^c, L_\natural})$$

obtained by using only finite tor-dimension of L with respect to A.

6.10

Let X, c be as in 6.5, and let $L \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{\Lambda[G]}X)$. For

$$u \in \mathrm{Hom}_{\Lambda[G]}(c_1^* L, c_2^! L),$$

6.5.9 gives a local trace

$$\mathrm{Tr}_{\Lambda[G]}(u) \in H^0(X^c, K\Lambda[G]_{X^c,\natural}) = H^0(X^c, K_{X^c} \otimes \Lambda[G_\natural]), \tag{6.10.1}$$

where $G_\natural$ is the set of conjugacy classes of G. For every $x \in G_\natural$, one may consider the "value of $\mathrm{Tr}_{\Lambda[G]}(u)$ at x,"

$$\mathrm{Tr}_{\Lambda[G]}(u)(x) \in H^0(X^c, K_{X^c}),$$

the image of $\mathrm{Tr}_{\Lambda[G]}(u)$ under the projection

$$H^0(X^c, K_{X^c} \otimes \Lambda[G_\natural]) \longrightarrow H^0(X^c, K_{X^c})$$

defined by x. It follows from 6.7.5 and 5.11.2 that

$$\mathrm{Tr}_\Lambda(u) = |G|\ \mathrm{Tr}_{\Lambda[G]}(u)(e), \tag{6.10.2}$$

where e denotes the identity element of G.

More generally, let $g \in G$, let Z_g be the centralizer of g, and let

$$gu \in \mathrm{Hom}_{\Lambda[Z_g]}(c_1^* L, c_2^! L)$$

be the correspondence obtained by composing u with left multiplication by $g : c_1^* L \to c_1^* L$. We have $L \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{\Lambda[Z_g]}X)$, and hence 6.10.2 implies

$$\mathrm{Tr}_\Lambda(gu) = |Z_g|\ \mathrm{Tr}_{\Lambda[Z_g]}(gu)(e). \tag{6.10.3}$$

By the same argument as in 5.11.3, one deduces from 6.7.4 the formula

$$\mathrm{Tr}_{\Lambda[Z_g]}(gu)(e) = \mathrm{Tr}_{\Lambda[G]}(u)(g^{-1}), \tag{6.10.4}$$

which allows 6.10.3 to be rewritten, if desired, in the form

$$\mathrm{Tr}_\Lambda(gu) = |Z_g|\ \mathrm{Tr}_{\Lambda[G]}(u)(g^{-1}). \tag{6.10.5}$$

6.11

Let $f : X \to Y$ be a proper G-S-morphism, and let

$$\begin{array}{ccc} C & \xrightarrow{c} & X \times_S X \\ \downarrow & & \downarrow{\scriptstyle f\times_S f} \\ D & \xrightarrow[d]{} & Y \times_S Y \end{array} \tag{6.11.1}$$

be a commutative G-equivariant square of G-S-schemes, with c and d proper. Assume that G acts trivially on Y and D. We denote by

$$f^{c/d} \quad (\text{or } f^c) : X^c \longrightarrow Y^d \tag{6.11.2}$$

the morphism induced by 6.11.1 on the schemes of fixed points of c and d, with the notation of 6.5.1. Let $L \in \mathrm{ob}\, D_{\mathrm{ctf}}(G, {}_A X)$, and let

$$u \in \mathrm{Hom}(c_1^* L, c_2^! L)$$

be a G-equivariant correspondence with support in c. By direct image, it gives a G-equivariant correspondence

$$f_* u \in \mathrm{Hom}_{\Lambda[G]}(d_1^* f_* L, d_2^! f_* L).$$

For $g \in G$, let Z_g denote the centralizer of g, and let

$$gu \in \mathrm{Hom}((gc)_1^* L, c_2^! L) \tag{6.11.3}$$

be the Z_g-equivariant correspondence with support in

$$gc \overset{\mathrm{dfn}}{=} (gc_1 = c_1 g, c_2) : C \to X \times_S X, \tag{6.11.4}$$

defined as the composite of the arrows

$$g^*(c_1^* L) \xrightarrow{\alpha_g} c_1^* L \xrightarrow{u} c_2^! L,$$

where α_g is the arrow giving the action of G on c_1^*L. It is clear that

$$f_*(gu) = g(f_*u). \tag{6.11.5}$$

Proposition 6.12. Under the hypotheses of 6.11, assume that

$$f_*L \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{\Lambda[G]}Y).$$

Then, for every $g \in G$,

$$f_*^{gc} \mathrm{Tr}_\Lambda(gu) = |Z_g|\ \mathrm{Tr}_{\Lambda[G]}(f_*u)(g^{-1}), \tag{6.12.1}$$

where

$$f_*^{gc} : H^0(X^{gc}, K_{X^{gc}}) \longrightarrow H^0(Y^d, K_{Y^d})$$

is the "Gysin" morphism defined by the adjunction arrow

$$f_*^{gc} K_{X^{gc}} = f_*^{gc} f^{gc!} K_{Y^d} \longrightarrow K_{Y^d}.$$

Indeed, by 6.10.5 applied to f_*u, and by 6.11.5, one has

$$\mathrm{Tr}_\Lambda(f_*(gu)) = |Z_g|\ \mathrm{Tr}_{\Lambda[G]}(f_*u)(g^{-1}),$$

and 6.12.1 therefore follows from the Lefschetz formula (III 4.5.1).

6.13

Let ℓ be a prime number distinct from p. For every integer $n \geq 1$, put

$$\Lambda_n = \mathbb{Z}/\ell^n.$$

Under the hypotheses of 6.11, let $L = (L_n)$ be a projective system of objects of

$$D_{\mathrm{ctf}}(G, X, \Lambda_n)$$

such that

$$L_m \overset{\mathrm{L}}{\otimes}_{\Lambda_m} \Lambda_n \xrightarrow{\sim} L_n \quad (m \geq n),$$

and let

$$u \in \mathrm{Hom}(c_1^*L, c_2^!L)$$

be a projective system of equivariant correspondences $u_n \in \mathrm{Hom}(c_1^*L_n, c_2^!L_n)$ such that, for $m \geq n$,

$$u_m \overset{\mathrm{L}}{\otimes}_{\Lambda_m} \Lambda_n = u_n$$

modulo the isomorphism $L_m \overset{\mathrm{L}}{\otimes}_{\Lambda_m} \Lambda_n = L_n$. By compatibility of local traces with extension of scalars, the local terms, for $g \in G$,

$$\mathrm{Tr}_{\Lambda_n}(gu_n) \in H^0(X^{gc}, K\Lambda_{n,X^{gc}})$$

define an element

$$\mathrm{Tr}_{\mathbb{Z}_\ell}(gu) \in H^0(X^{gc}, K_{\ell,X^{gc}}) \overset{\mathrm{dfn}}{=} \varprojlim_n H^0(X^{gc}, K\Lambda_{n,X^{gc}}),$$

and the terms

$$f_*^{gc}\,\mathrm{Tr}_{\Lambda_n}(gu_n) = \mathrm{Tr}_{\Lambda_n}(gf_*u_n)$$

an element

$$f_*\,\mathrm{Tr}_{\mathbb{Z}_\ell}(gu) \in H^0(Y^d, K_{\ell,Y^d}) \overset{\mathrm{dfn}}{=} \varprojlim_n H^0(Y^d, K\Lambda_{n,Y^d}).$$

Assume moreover that

$$f_*M_n \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{\Lambda_n[G]}Y)$$

for all n. Then the local traces

$$\mathrm{Tr}_{\Lambda_n[G]}(f_*u_n)$$

similarly define an element

$$\mathrm{Tr}_{\mathbb{Z}_\ell[G]}(f_*u) \in H^0(Y^d, K\mathbb{Z}_\ell[G]_{Y^d,\natural}) \overset{\mathrm{dfn}}{=} \varprojlim_n H^0(Y^d, K\Lambda_n[G]_{Y^d,\natural}).$$

It follows from 6.12 that

$$f_*^{gc}\,\mathrm{Tr}_{\mathbb{Z}_\ell}(gu) = |Z_g|\ \mathrm{Tr}_{\mathbb{Z}_\ell[G]}(f_*u)(g^{-1}). \tag{6.13.1}$$

6.14

Let X be a G-S-scheme, let $j : U \to X$ be an equivariant open immersion, and let

$$c : C \to X \times_S X$$

be a morphism of G-S-schemes such that $c_2(= p_2c) : C \to X$ is quasi-finite and of finite tor-dimension. Suppose that

$$c_1^{-1}(U) \subset c_2^{-1}(U).$$

Then there are commutative squares

$$\begin{array}{ccccc}
U & \longleftarrow & c_1^{-1}(U) & & \\
\downarrow{\scriptstyle i} & & \downarrow & & \\
X & \xleftarrow{c_1} & C & \xrightarrow{c_2} & X \\
\uparrow{\scriptstyle j} & & \uparrow & & \uparrow \\
X-U & \longleftarrow & c_2^{-1}(X-U) & \longrightarrow & X-U
\end{array} \tag{6.14.1}$$

The trace morphism

$$\mathrm{Tr}_{c_2} : c_{2!}\Lambda_C \longrightarrow \Lambda_X$$

then defines a filtered G-equivariant correspondence

$$\underline{c} \in \mathrm{Hom}(c_1^*\Lambda_X, c_2^!\Lambda_X), \tag{6.14.2}$$

where Λ_X is endowed with the filtration defined by the submodule $i_!\Lambda_U$, that is,

$$F^n\Lambda_X = \Lambda_X \quad (n \le 0), \qquad F^1\Lambda_X = i_!\Lambda_U, \qquad F^n\Lambda_X = 0 \quad (n \ge 1).$$

The associated graded consists of two G-equivariant correspondences

$$\mathrm{gr}^0\,\underline{c} = \underline{c}_{X-U,X} \in \mathrm{Hom}(c_1^*\Lambda_{X-U,X}, c_2^!\Lambda_{X-U,X}),$$
$$\mathrm{gr}^1\,\underline{c} = \underline{c}_{U,X} \in \mathrm{Hom}(c_1^*\Lambda_{U,X}, c_2^!\Lambda_{X-U,X}), \tag{6.14.3}$$

where we have put

$$\Lambda_{X-U,X} = j_*\Lambda_{X-U}, \qquad \Lambda_{U,X} = i_!\Lambda_U.$$

We have

$$\underline{c}_{X-U,U} = j_*\underline{c}_{X-U}, \tag{6.14.4}$$

where

$$\underline{c}_{X-U} \in \mathrm{Hom}(c_1^*\Lambda_{X-U}, c_2^!\Lambda_{X-U})$$

is the correspondence defined by $\mathrm{Tr}_{c_2,X-U}$. We write $\underline{c}$, $\underline{c}_{U,X}$, and so on, when we want to specify the base ring.

Forgetting the action of G, there are local terms

$$\mathrm{Tr}_\Lambda(\underline{c}), \quad \mathrm{Tr}_\Lambda(\underline{c}_{U,X}), \quad \mathrm{Tr}_\Lambda(\underline{c}_{X-U,X}) \in H^0(X^c, K_{X^c}), \tag{6.14.5}$$

which, by additivity of traces (III 4.13.1), satisfy the relation

$$\mathrm{Tr}_\Lambda(\underline{c}) = \mathrm{Tr}_\Lambda(\underline{c}_{U,X}) + \mathrm{Tr}_\Lambda(\underline{c}_{X-U,X}). \tag{6.14.6}$$

Moreover, by 6.14.4,

$$\mathrm{Tr}_\Lambda(\underline{c}_{X-U,X}) = j_*^c\,\mathrm{Tr}_\Lambda(\underline{c}_{X-U}), \tag{6.14.7}$$

where

$$j_*^c : H^0((X-U)^c, K_{(X-U)^c}) \longrightarrow H^0(X^c, K_{X^c})$$

is the direct-image morphism defined by $j^c : (X-U)^c \to X^c$. Recall (III 4.3) that, if X is smooth, c a closed immersion, and X^c finite, $\mathrm{Tr}_\Lambda(\underline{c})$ is the image in Λ of the intersection multiplicity $(C \cdot X)$ of C with the diagonal. If, moreover, $X-U$ is smooth, $\mathrm{Tr}_\Lambda(\underline{c}_{X-U})$ is the image in Λ of $(c_2^{-1}(X-U)\cdot(X-U))$. Note also that, if $X-U$ is proper over S and $c|X-U$ is the diagonal, then the Lefschetz formula (III 4.7) implies that

$$\int_{X-U} \mathrm{Tr}(\underline{c}_{X-U}) \in \Lambda$$

is the Euler–Poincaré characteristic of $X-U$ with values in Λ.

6.15

Let there be a G-equivariant diagram 6.11.1, with f, c, d proper, and an equivariant open immersion $U \to X$. Suppose that c_2 is quasi-finite and of finite tor-dimension, that

$$c_1^{-1}(U) \subset c_2^{-1}(U),$$

that G acts trivially on C and D, and that

$$f|U : U \longrightarrow f(U) = V$$

is an étale Galois covering with group G. This last hypothesis implies that

$$Rf_*(\Lambda_{U,X}) \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{\Lambda[G]}Y) :$$

indeed $Rf_*(\Lambda_{U,X})$ is concentrated in degree 0 and is extension by zero of a sheaf on V locally isomorphic to $\Lambda[G]$. Hence one may apply 6.12 to $L = \Lambda_{U,X}$, $u = \underline{c}_{U,X}$, and, in view of 6.14.6 and 6.14.7, one obtains:

Proposition 6.16. Under the hypotheses of 6.15, for every $g \in G$ one has

$$f_*^{gc}\,\mathrm{Tr}_\Lambda(g\underline{c}) - (fj)_*^{gc}\,\mathrm{Tr}_\Lambda(g\underline{c}_{X-U}) = |Z_g|\ \mathrm{Tr}_{\Lambda[G]}(f_*\underline{c}_{U,X})(g^{-1}), \tag{6.16.1}$$

where $j : X - U \to X$ is the inclusion, and Z_g denotes the centralizer of g.

Applying 6.16 to the projective system of correspondences $\underline{c}_\ell = (\underline{c}_{\Lambda_n})$, where $\Lambda_n = \mathbb{Z}/\ell^n$ with ℓ prime distinct from p, and taking into account that 6.14.6 and 6.14.7 give, after passage to the limit and application of f_*^{gc},

$$f_*^{gc}\,\mathrm{Tr}_{\mathbb{Z}_\ell}(g\underline{c}_\ell) = f_*^{gc}\,\mathrm{Tr}_{\mathbb{Z}_\ell}(g\underline{c}_{\ell,U,X}) + (fj)_*^{gc}\,\mathrm{Tr}_{\mathbb{Z}_\ell}(g\underline{c}_{\ell,X-U}),$$

one deduces, by 6.13:

Corollary 6.17. Under the hypotheses of 6.15, for every $g \in G$ one has

$$f_*^{gc}\,\mathrm{Tr}_{\mathbb{Z}_\ell}(g\underline{c}_\ell) - (fj)_*^{gc}\,\mathrm{Tr}_{\mathbb{Z}_\ell}(g\underline{c}_{\ell,X-U}) = |Z_g|\ \mathrm{Tr}_{\mathbb{Z}_\ell[G]}(f_*\underline{c}_{\ell,U,X})(g^{-1}), \tag{6.17.1}$$

with the notation of 6.16.

In view of the compatibility of local traces with localization and of the remarks made in 6.14, one sees that 6.17 gives an affirmative solution, in a more general formulation, to Grothendieck's divisibility conjecture (XII 4.5), in the case where the endomorphism φ of G considered in loc. cit. is the identity.

In fact, by following 5.13, it is not difficult to give divisibility statements analogous to 6.12, 6.13, 6.16, 6.17, in the case where c is not G-equivariant, but where c_2 is and c_1 satisfies

$$c_1(xg) = c_1(x)\varphi(g)$$

for every point x of G, φ being a given endomorphism of G. The divisibility formulas are then written as above, with Z_g replaced by the φ-centralizer of g^{-1} (5.13.5).

6.18

Put

$$N_G = \sum_{g\in G} g \in \Lambda[G]. \tag{6.18.1}$$

Let X be an S-scheme. For $L \in \mathrm{ob}\, D({}_{\Lambda[G]}X)$, left multiplication by N_G induces an arrow in $D(X)$

$$N_G : \Lambda \overset{\mathrm{L}}{\otimes}_{\Lambda[G]} L \longrightarrow \mathrm{RHom}_{\Lambda[G]}(\Lambda, L), \tag{6.18.2}$$

where Λ is regarded as a $\Lambda[G]$-algebra by the natural augmentation sending every $g \in G$ to 1.

Lemma 6.18.3. If $L \in \operatorname{ob} D_{\mathrm{ctf}}({}_{\Lambda[G]}X)$, the arrow 6.18.2 is an isomorphism.

By dévissage, one reduces to the case where L is perfect, then to $L = \Lambda[G]$, and the assertion follows from the fact that N_G (6.18.1) is a basis of the module of G-invariants of the left $\Lambda[G]$-module $\Lambda[G]$.

Proposition 6.19. In the situation of 6.11, let $M \in \operatorname{ob} D_{\mathrm{ctf}}(Y)$,

$$v \in \operatorname{Hom}(d_1^* M, d_2^! M),$$

and let $a : M \to f_* L$ be an arrow in $D({}_{\Lambda[G]}Y)$, where M is regarded as an object of $D({}_{\Lambda[G]}Y)$ by the augmentation $\Lambda[G] \to \Lambda$, such that the square

$$\begin{array}{ccc} d_1^* M & \xrightarrow{v} & d_2^! M \\ \downarrow & & \downarrow \\ d_1^* f_* L & \xrightarrow[f_* u]{} & d_2^! f_* L \end{array}$$

is commutative. Suppose that $f_* M \in \operatorname{ob} D_{\mathrm{ctf}}({}_{\Lambda[G]}Y)$ and that a induces an isomorphism

$$M \xrightarrow{\sim} \operatorname{RHom}_{\Lambda[G]}(\Lambda, f_* L).$$

Then

$$\operatorname{Tr}_\Lambda(v) = \sum_{g \in G_\natural} \operatorname{Tr}_{\Lambda[G]}(f_* u)(g^{-1}). \tag{6.19.1}$$

By 6.18.3, a, composed with N_G^{-1}, gives an isomorphism

$$M \xrightarrow{\sim} \Lambda \overset{\mathrm{L}}{\otimes}_{\Lambda[G]} f_* L,$$

under which v is identified with

$$\Lambda \overset{\mathrm{L}}{\otimes}_{\Lambda[G]} f_* u.$$

By 6.7.2, $\operatorname{Tr}_\Lambda(v)$ is therefore the image of $\operatorname{Tr}_{\Lambda[G]}(f_* u)$ under the arrow induced by the augmentation

$$\Lambda[G] \longrightarrow \Lambda.$$

This augmentation, by definition, sends every conjugacy class to 1, whence the conclusion.

6.20

Let, for $i = 1, 2$, X_i be a G-S-scheme, and let

$$X = X_1 \times_S X_2, \qquad c : C \to X$$

be a G-S-morphism such that c_2 is quasi-finite and of finite tor-dimension. Let $L_i \in \operatorname{ob} D^+(G, {}_A X_i)$. The trace morphism

$$\operatorname{Tr}_{c_2} : c_{2!} c_2^* L_2 \longrightarrow L_2$$

defines by adjunction an arrow in $D(G,X)$, again denoted

$$\mathrm{Tr}_{c_2} : c_2^* L_2 \longrightarrow c_2^! L_2, \tag{6.20.1}$$

which associates to every G-equivariant morphism

$$u \in \mathrm{Hom}(c_1^* L_1, c_2^* L_2)$$

a G-equivariant correspondence

$$u^! = \mathrm{Tr}_{c_2} \circ u \in \mathrm{Hom}(c_1^* L_1, c_2^! L_2). \tag{6.20.2}$$

Proposition 6.21. Let $f : X \to Y$ be a proper G-morphism, and let 6.11.1 be an equivariant commutative square, with trivial action of G on Y and D. Suppose c, d are proper, c_2, d_2 quasi-finite and of finite tor-dimension, and the square

$$\begin{array}{ccc} C & \xrightarrow{c_2} & X \\ {\scriptstyle h}\downarrow & & \downarrow{\scriptstyle f} \\ D & \xrightarrow[d_2]{} & Y \end{array}$$

is cartesian and tor-independent (SGA 6 III 1.5). Let $M \in \mathrm{ob}\, D_{\mathrm{ctf}}(Y)$,

$$v \in \mathrm{Hom}(d_1^* M, d_2^* M),$$

hence a G-equivariant homomorphism

$$h^* v \in \mathrm{Hom}(c_1^* f^* M, c_2^* f^* M),$$

and G-equivariant correspondences

$$(h^* v)^! \in \mathrm{Hom}(c_1^* f^* M, c_2^! f^* M), \qquad f_*((h^* v)^!) \in \mathrm{Hom}(d_1^*(f_* f^* M), d_2^!(f_* f^* M)).$$

Then there is a commutative square of arrows in $D({}_{\Lambda[G]}Y)$, where M is regarded as an object of $D({}_{\Lambda[G]}Y)$ by the trivial action,

$$\begin{array}{ccc} d_1^* M & \xrightarrow{v^!} & d_2^! M \\ \downarrow & & \downarrow \\ d_1^* f_* f^* M & \xrightarrow[f_*((h^* v)^!)]{} & d_2^! f_* f^* M, \end{array}$$

where the vertical arrows are given by the adjunction arrow $M \to f_* f^* M$.

Put $h^* v = u$, $f^* M = L$, and consider the diagram

$$\begin{array}{ccccc} d_1^* M & \xrightarrow{v} & d_2^* M & \xrightarrow{\mathrm{Tr}_{d_2}} & d_2^! M \\ \downarrow & & \downarrow & & \downarrow \\ d_1^* f_* L & \longrightarrow & h_* c_1^* L & \xrightarrow{h_* \mathrm{Tr}_{c_2}} & h_* c_2^! L \longrightarrow d_2^! f_* L. \end{array}$$

The arrows (1) and (3) are given by the adjunction arrow $M \to f_*L$, (2) by the adjunction arrow $d_2^*M \to h_*h^*(d_2^*M) = h_*c_2^*L$, (4) by the base-change arrow, and (5) is the canonical isomorphism (SGA 4 XVIII 3.1.12.3). By definition, $v^!$ is the composite of the upper row. On the other hand, it follows from the interpretation of the direct image of a correspondence (III 3.5 b), 3.7) that $f_*u^!$ is the composite of the lower row. It remains only to prove commutativity of the squares (A) and (B). The commutativity of (A) follows immediately from the definition of the base-change arrow. As for (B), it follows from the fact that, in view of the tor-independence hypothesis, Tr_{d_2} is compatible with base change by f (SGA $4^{1/2}$ Cycle 2.3.3).

Applying 6.19, one obtains:

Corollary 6.22. Under the hypotheses of 6.21, assume that

$$f_*f^*M \in \mathrm{ob}\, D_{\mathrm{ctf}}(_{\Lambda[G]}Y),$$

and that the adjunction arrow

$$M \to f_*f^*M$$

induces an isomorphism

$$M \xrightarrow{\sim} \mathrm{RHom}_{\Lambda[G]}(\Lambda, f_*f^*M).$$

Then

$$\mathrm{Tr}_\Lambda(v^!) = \sum_{g \in G_\natural} \mathrm{Tr}_{\Lambda[G]}(f_*((f^*v)^!))(g^{-1}). \tag{6.22.1}$$

Proposition 6.23. Under the hypotheses of 6.21, suppose moreover that there is an open immersion

$$i : V \hookrightarrow Y$$

such that $(fc_1)^{-1}(V)$ is connected, that $d_1^{-1}(V) \subset d_2^{-1}(V)$, and that f induces a principal Galois covering with group G,

$$f_V : U = f^{-1}(V) \to V.$$

Suppose also that M is of the form $M = i_!E$, where $E \in \mathrm{ob}\, D(V)$, and that there is an isomorphism

$$\alpha : f_V^*E \xrightarrow{\sim} \Lambda_X \overset{\mathrm{L}}{\otimes}_\Lambda E_0$$

in $D(G, X)$, with $E_0 \in \mathrm{ob}\, D(\Lambda[G])$, perfect over Λ. Let

$$v \in \mathrm{Hom}(d_1^*M, d_2^*M)$$

be as in 6.21, and let

$$v_0 \in \mathrm{Hom}_{\Lambda[G]}(E_0, E_0)$$

be the homomorphism defined, thanks to α, by $f^*v|c_1^{-1}(U)$. Then, if $\underline{c}_{U,X}$ denotes the correspondence defined in 6.14.3, with the notation 6.20.2 one has

$$\mathrm{Tr}_\Lambda(v^!) = \sum_{g \in G_\natural} \mathrm{Tr}_{\Lambda[G]}(f_*\underline{c}_{U,X})(g^{-1})\, \mathrm{Tr}_\Lambda(gv_0). \tag{6.23.1}$$

Note that, by the central character of Tr_Λ, the right hand side does not depend on the choice of α.

By the projection formula

$$f_*f^*\Lambda_Y \overset{\mathrm{L}}{\otimes} M \xrightarrow{\sim} f_*f^*M$$

and 6.15, M satisfies the hypotheses of 6.22. On the other hand, α defines an isomorphism

$$f^*M \xrightarrow{\sim} \Lambda_{U,X} \otimes E_0$$

under which $(f^*v)^!$ is identified with the external tensor product $\underline{c}_{U,X} \otimes v_0$. By the projection formula, f_*f^*M is therefore identified with $f_*(\Lambda_{U,X}) \otimes E_0$, and $f_*((f^*v)^!)$ with the external tensor product $f_*\underline{c}_{U,X} \otimes v_0$. For $g \in G$, the Z_g-equivariant correspondence $gf_*((f^*v)^!)$ is therefore identified with

$$gf_*\underline{c}_{U,X} \otimes gv_0.$$

Since, by 6.10.4,

$$\mathrm{Tr}_{\Lambda[G]}(f_*((f^*v)^!))(g^{-1}) = \mathrm{Tr}_{\Lambda[Z_g]}(gf_*((f^*v)^!))(e),$$

it is enough, in view of 6.22.1, to prove the formula

$$\mathrm{Tr}_{\Lambda[Z_g]}(gf_*\underline{c}_{U,X} \otimes gv_0)(e) = \mathrm{Tr}_{\Lambda[G]}(f_*\underline{c}_{U,X})(g^{-1})\,\mathrm{Tr}_\Lambda(gv_0),$$

or, equivalently by 6.10.4,

$$\mathrm{Tr}_{\Lambda[Z_g]}(gf_*\underline{c}_{U,X} \otimes gv_0)(e) = \mathrm{Tr}_{\Lambda[Z_g]}(gf_*\underline{c}_{U,X})(e)\,\mathrm{Tr}_\Lambda(gv_0). \tag{6.23.2}$$

Replacing G by Z_g if necessary, we may suppose that $g = e$. Returning to the definition of the traces, one sees that it is enough to establish the following lemma.

Lemma 6.23.3. (cf. SGA $4^{1/2}$ Report 4.7). Let P be a G_V-module locally a direct factor of a free module of finite type, let $P' = i_!P$, and let Q be a complex of $\Lambda[G]$-modules, perfect over Λ. Then $P \overset{\mathrm{L}}{\otimes}_\Lambda Q$, considered as an object of $D({}_{\Lambda[G]}V)$ by the diagonal action of G, is perfect over $\Lambda[G]$, and there is a commutative square

$$\begin{array}{ccc} \delta^*\mathrm{RHom}_{\Lambda[G]}(p_1^*P', p_2^!P') \overset{\mathrm{L}}{\otimes}_\Lambda \mathrm{RHom}_{\Lambda[G]}(Q,Q) & \xrightarrow{(1)} & K_Y \\ \downarrow{\scriptstyle (2)} & & \| \\ \delta^*\mathrm{RHom}_{\Lambda[G]}(p_1^*P' \overset{\mathrm{L}}{\otimes}_\Lambda Q, p_2^!P' \overset{\mathrm{L}}{\otimes}_\Lambda Q) & \xrightarrow[(3)]{} & K_Y, \end{array} \tag{*}$$

where $\delta : Y \to Y \times_S Y$ is the diagonal, the upper horizontal arrow is the tensor product of the arrows

$$\delta^*\mathrm{RHom}_{\Lambda[G]}(p_1^*P', p_2^!P') \xrightarrow{6.5.3} K\Lambda[G]_{Y,\natural} \xrightarrow{x \mapsto x(e)} K_Y$$

and

$$\mathrm{RHom}_{\Lambda[G]}(Q,Q) \xrightarrow{\mathrm{Tr}_\Lambda} \Lambda,$$

the vertical arrow is deduced from the external tensor product by restriction along the diagonal

$$\Lambda[G] \to \Lambda[G] \otimes \Lambda[G],$$

and the lower horizontal arrow is the composite of 6.5.3 (defined because $P' \overset{\mathrm{L}}{\otimes}_\Lambda Q \in \mathrm{ob}\, D_{\mathrm{ctf}}({}_{\Lambda[G]}Y)$) and of $x \mapsto x(e)$.[20]

[20] One should be able to replace P by a perfect complex (over $\Lambda[G]$) (or even P' by an object of $D_{\mathrm{ctf}}({}_{\Lambda[G]}Y)$).

The first assertion is evident, for one reduces to $P = \Lambda[G]_V$, and $P \overset{\mathrm{L}}{\otimes}_\Lambda Q$ is then isomorphic to the tensor product of P by Q considered with the trivial action of G. For the second, first note that, by 6.5.4 and 6.5.5, one has

$$\delta^*\mathrm{RHom}_{\Lambda[G]}(p_1^*P', p_2^!P') \xrightarrow{\sim} D_{\Lambda[G]}(i_!P) \overset{\mathrm{L}}{\otimes}_{\Lambda[G]} i_!P \xrightarrow{\sim} i_!(D_{\Lambda[G]}P \overset{\mathrm{L}}{\otimes}_{\Lambda[G]} P),$$

so that we are reduced to checking that the square induced by (*) on V commutes. We may therefore suppose that $V = Y$. The square (*) then reads

$$\begin{array}{ccc} \mathrm{RHom}_{\Lambda[G]}(P, K_Y \overset{\mathrm{L}}{\otimes} P) \overset{\mathrm{L}}{\otimes} \mathrm{RHom}_{\Lambda[G]}(Q,Q) & \xrightarrow{(1)} & K_Y \\ \downarrow{\scriptstyle (2)} & & \| \\ \mathrm{RHom}_{\Lambda[G]}(P \overset{\mathrm{L}}{\otimes} Q, K_Y \overset{\mathrm{L}}{\otimes} P \overset{\mathrm{L}}{\otimes} Q) & \xrightarrow[(3)]{} & K_Y, \end{array} \qquad (**)$$

where (2) is the external tensor product, (1) is given by

$$\mathrm{Tr}_{\Lambda[G]}(-)(e) \otimes \mathrm{Tr}_\Lambda,$$

(traces in the sense of no. 5), and (3) by $\mathrm{Tr}_{\Lambda[G]}(-)(e)$. By descent, one reduces to $P = \Lambda[G]_Y$, and, by the initial remark, one may then suppose that G acts trivially on Q. The assertion is then an immediate consequence of 5.12.5.

6.24

If Λ is annihilated by a power of a prime number $\ell \neq p$, the right hand side of 6.23.1 may be rewritten in the form

$$\sum_{g \in G_\natural} \mathrm{Tr}_{\mathbb{Z}_\ell[G]}(f_* \underline{c}_{\ell,U,X})(g^{-1}) \, \mathrm{Tr}_\Lambda(gv_0),$$

with the notation of 6.17. Formula 6.17.1 shows that the local terms defined by Grothendieck in (XII 6.2) coincide with Verdier's local terms, at least when the endomorphism φ of G considered in loc. cit. is the identity; but, as already observed, this restriction is not serious. If Y is proper over S, then by conjugating 6.23.1 with the Lefschetz formula for $Y \to S$ (III 4.7), one obtains a formula generalizing (XII 6.3), and a fortiori the Lefschetz formula for Frobenius proved in (SGA $4^{1/2}$ Report) and Part I of the present exposé.

Exposé V. J-adic Projective Systems

by J.-P. Jouanolou

Throughout this exposé, the letter A denotes a ring with unit. The present exposé is intended to develop a formalism which will be used in the following exposé for the study of ℓ-adic cohomology.

1. Generalities on abelian A-categories

Definition 1.1. An A-category (resp. an abelian A-category) is a pair $(\mathcal{C}, \rho)$ formed by an additive (resp. abelian) category $\mathcal{C}$ and a homomorphism of rings

$$\rho : A \longrightarrow \mathrm{End}(\mathrm{id}_{\mathcal{C}})$$

from A to the ring of endomorphisms of the identity functor from $\mathcal{C}$ to $\mathcal{C}$.

Given two A-categories (resp. abelian A-categories) $(\mathcal{C}, \rho)$ and $(\mathcal{C}', \rho')$, a morphism of A-categories (resp. of abelian A-categories) from $(\mathcal{C}, \rho)$ to $(\mathcal{C}', \rho')$ is an additive (resp. exact) functor $F : \mathcal{C} \to \mathcal{C}'$ such that, for every object M of $\mathcal{C}$ and every element a of A, the equality below is satisfied:

$$F(\rho(a)_M) = \rho'(a)_{F(M)}.$$

Example 1.1.1

Let $\mathcal{C}$ be an additive (resp. abelian) category. Recall that the category of left $(A, \mathcal{C})$-modules, denoted $(A, \mathcal{C})$-mod, is the category described as follows:

(i) Its objects are pairs (X, α) consisting of an object X of $\mathcal{C}$ and a homomorphism of rings

$$\alpha : A \longrightarrow \mathrm{Hom}_{\mathcal{C}}(X, X).$$

(ii) A morphism $(X, \alpha) \to (Y, \beta)$ is a $\mathcal{C}$-morphism $u : X \to Y$ such that, for every element a of A, the following diagram is commutative:

$$\begin{array}{ccc} X & \xrightarrow{u} & Y \\ {\scriptstyle \alpha(a)}\downarrow & & \downarrow{\scriptstyle \beta(a)} \\ X & \xrightarrow[u]{} & Y. \end{array}$$

The category $(A, \mathcal{C})$-mod is evidently an $A^\natural$-category (resp. an abelian $A^\natural$-category), where $A^\natural$ is the centre of A. Moreover, it has the following properties:

(a) The functor $(A, \mathcal{C})$-mod $\to \mathcal{C}$ obtained by forgetting the A-module structure commutes with inductive and projective limits.

(b) Let I be a category. In order that the I-indexed inductive (resp. projective) limits of $(A, \mathcal{C})$-mod be representable, it is enough that this be so for the I-indexed inductive (resp. projective) limits of $\mathcal{C}$.

1.2. External tensor product

Let $(\mathcal{C}, \rho)$ be an abelian A-category. If M is a right A-module and X an object of $\mathcal{C}$, the external tensor product of X by M, denoted $M \otimes_A X$, is the covariant functor from $\mathcal{C}$ to the category of sets, defined on objects Y of $\mathcal{C}$ by the equality below and in the evident way on arrows:

$$(M \otimes_A X)(Y) = \mathrm{Hom}_A(M, \mathrm{Hom}_{\mathcal{C}}(X, Y)),$$

where $\mathrm{Hom}_{\mathcal{C}}(X, Y)$ is regarded as a right A-module via the action of A on X. Interpreting $M \otimes_A X$ and Y as objects of the category $\widehat{\mathcal{C}} = \mathrm{Hom}(\mathcal{C}, \mathrm{Ens})^\circ$, the preceding equality takes the more familiar form

$$\mathrm{Hom}_{\widehat{\mathcal{C}}}(M \otimes_A X, Y) = \underline{\mathrm{Hom}}_A(M, \mathrm{Hom}_{\mathcal{C}}(X, Y)).$$

If the functor $M \otimes_A X$ is representable, a representative will be denoted and named in the same way.

If $u : M \to M'$ and $v : X \to X'$ are two morphisms, respectively in (A-mod) and in $\mathcal{C}$, one defines in the usual way a $\mathcal{C}$-morphism

$$u \otimes_A v : M \otimes_A X \longrightarrow M' \otimes_A X',$$

which allows us to speak of the external tensor-product bifunctor, covariant in both variables. Its properties are summarized in the following proposition.

Proposition 1.2.1. The tensor-product bifunctor is additive and commutes with inductive limits.

The proof, classical in the case of modules over a ring, is immediate.

Proposition 1.2.2 (Representability criteria).

(a) For every object X of $\mathcal{C}$, $A \otimes_A X$ is represented by X.

(b) For every finitely presented A-module M and every object X of $\mathcal{C}$, the functor $M \otimes_A X$ is representable.

(c) If the category $\mathcal{C}$ has arbitrary direct sums, the functor $M \otimes_A X$ is representable for every pair (M, X).

Proof. Assertion (a) is clear. The other two assertions then follow from the lemma below, whose proof is immediate.

Lemma 1.2.3. Let $M \to N \to P \to 0$ be an exact sequence of A-modules and let X be an object of $\mathcal{C}$. If the functors $M \otimes_A X$ and $N \otimes_A X$ are represented by objects Y and Z of $\mathcal{C}$, then the functor $P \otimes_A X$ is represented by the cokernel of the morphism $Y \to Z$ corresponding to $\alpha \otimes_A \mathrm{id}_X$.

Remark 1.2.4

Let $\mathfrak{G}$ be an ideal of finite type of A. For every object X of $\mathcal{C}$, the functor $(A/\mathfrak{G}) \otimes_A X$ is representable, and the arrow

$$p_X : X \longrightarrow (A/\mathfrak{G}) \otimes_A X$$

coming from the canonical epimorphism from A onto $A/\mathfrak{G}$ and from part (a) of 1.2.2 is an epimorphism. The same statement remains valid when the ideal $\mathfrak{G}$ is no longer assumed to be of finite type, but $\mathcal{C}$ has arbitrary direct sums. Put $\mathfrak{G}X = \mathrm{Ker}(p_X)$. When the category has filtered inductive limits, it is clear that

$$\mathfrak{G}X = \sum_{a \in \mathfrak{G}} aX.$$

If $u : X \to Y$ is an epimorphism, u maps $\mathfrak{G}X$ epimorphically onto $\mathfrak{G}Y$. Finally, for an object X to be annihilated by every element of $\mathfrak{G}$, it is necessary and sufficient that $\mathfrak{G}X = 0$. Then every morphism from an object Z to X factors, by means of p_Z, through a morphism from $(A/\mathfrak{G}) \otimes_A Z$ to X.

2. The Mittag-Leffler-Artin-Rees condition

Throughout this paragraph, the letter $\mathcal{C}$ denotes an abelian category and we put

$$P = \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C}),$$

the category of projective systems indexed by the ordered set $\mathbb{N}$ of positive integers and with values in $\mathcal{C}$.

2.1. The Mittag-Leffler-Artin-Rees condition

Let $X = (X_n, u_n)_{n \geq 0}$ be an object of the category P. If r denotes an integer ≥ 0, we agree to write $X[r]$ for the projective system $(X_{n+r}, u_{n+r})_{n \geq 0}$. A morphism $h : X \to Y$ of P defines in the evident way a morphism denoted $h[r]$ from $X[r]$ to $Y[r]$, functorially. If r and s are two integers satisfying $s \geq r \geq 0$, the transition morphisms $X_{n+s} \to X_{n+r}$ $(n \geq 0)$ define a morphism

$$w_{sr} : X[s] \longrightarrow X[r],$$

and it is clear that, if t is a third integer with $t \geq s \geq r$, the equality below is satisfied:

$$w_{ts} \circ w_{sr} = w_{tr}.$$

In other words, we have thus associated to X an object $\overline{X}$ of the category $\mathrm{Hom}(\mathbb{N}^\circ, P)$. Moreover, if $h : X \to Y$ is a morphism of P, there corresponds to it in the evident way a morphism $\overline{h}$ from $\overline{X}$ to $\overline{Y}$, functorially. Finally, if

$$0 \longrightarrow X \xrightarrow{u} Y \xrightarrow{v} Z \longrightarrow 0$$

is an exact sequence of P, the corresponding sequence below in $\overline{P} = \mathrm{Hom}(\mathbb{N}^\circ, P)$ is exact:

$$0 \longrightarrow \overline{X} \xrightarrow{\overline{u}} \overline{Y} \xrightarrow{\overline{v}} \overline{Z} \longrightarrow 0.$$

Definition 2.1.1. Let an object of the category P be given. It is said to satisfy the Mittag-Leffler-Artin-Rees condition (abbreviated MLAR) if there exists an integer r such that, for every integer $s \geq r$, the equality below is satisfied:

$$\mathrm{Im}(X[s] \xrightarrow{w_{s0}} X) = \mathrm{Im}(X[r] \xrightarrow{w_{r0}} X).$$

Equivalently, for every integer $n \geq 0$, the images of X_{n+r} and X_{n+s} in X_n by the "transition morphisms" are the same. Finally, a third interpretation is that the associated projective system $\overline{X}$ satisfies the Mittag-Leffler condition (abbreviated ML) (EGA 0_{III} 13.1.2). The following proposition is deduced from this by (EGA 0_{III} 13.2.1).

Proposition 2.1.2. Let

$$0 \longrightarrow X \longrightarrow Y \longrightarrow Z \longrightarrow 0$$

be an exact sequence of P.

(i) If Y satisfies (MLAR), then Z satisfies (MLAR).

(ii) If X and Z satisfy (MLAR), then Y satisfies (MLAR).

2.2. AR-null projective systems

Definition 2.2.1. Let X be an object of the category P. It is called AR-null if there exists an integer $r \geq 0$ such that the canonical morphism $X[r] \to X$ is zero.

It is clear in particular that an AR-null projective system satisfies the condition (MLAR).

Proposition 2.2.2. Let

$$0 \longrightarrow X \longrightarrow Y \longrightarrow Z \longrightarrow 0$$

be an exact sequence of P. The following assertions are equivalent:

(i) Y is AR-null;

(ii) X and Z are AR-null.

In other words, the full subcategory P_0 of P, whose objects are the AR-null projective systems, is thick in P.

Proof. It is clear that (i) implies (ii). Conversely, let r and t be integers satisfying the condition of Definition 2.2.1 for X and Z respectively. One sees immediately that the integer $r+t$ satisfies the conditions of Definition 2.2.1 for Y.

2.3. Reminders on the calculus of fractions and applications

Let $\mathcal{E}$ be a category and S a subset of $\mathrm{Fl}(\mathcal{E})$. A category of fractions of $\mathcal{E}$ with respect to S is a pair $(p, \mathcal{E}(S^{-1}))$ consisting of a category $\mathcal{E}(S^{-1})$ and a functor $p : \mathcal{E} \to \mathcal{E}(S^{-1})$ satisfying the following universal property: for a functor u from $\mathcal{E}$ to a category $\mathcal{F}$ to factor through p, it is necessary and sufficient that it make all arrows belonging to S invertible; the factorization is then unique. The uniqueness of such a pair up to isomorphism is clear. We refer the reader to Exposé I of the Séminaire Homotopique de Strasbourg for the proof of existence, and also for most of the results stated without proof in what follows in this paragraph. See also P. Gabriel and M. Zisman, *Calculus of fractions and homotopy theory*, Erg. der Math., 35, Springer-Verlag, 1967.

Certain properties of the multiplicative part S ensure a simple description of the category $\mathcal{E}(S^{-1})$.

Definition 2.3.1. A subset S of $\mathrm{Fl}(\mathcal{E})$ is said to admit a right calculus of fractions if the following conditions hold:

(a) The identity arrows of $\mathcal{E}$ belong to S.

(b) If $u : X \to Y$ and $v : Y \to Z$ belong to S, the composite $v \circ u$ belongs to S.

(c) Every diagram of type (D_1) below, in which t belongs to S, can be completed to a diagram of type (D_2), in which s belongs to S:

$$(D_1) \qquad X \xrightarrow{u} Y \xleftarrow{t} Y'$$

$$(D_2) \qquad \begin{array}{ccc} X' & \xrightarrow{u'} & Y' \\ {\scriptstyle s}\downarrow & & \downarrow{\scriptstyle t} \\ X & \xrightarrow[u]{} & Y. \end{array}$$

(d) For every commutative diagram

$$X \underset{g}{\overset{f}{\rightrightarrows}} Y \xrightarrow{s} Z,$$

in which s belongs to S, there exists a commutative diagram

$$T \xrightarrow[t]{} X \underset{g}{\overset{f}{\rightrightarrows}} Y,$$

in which t belongs to S.

Dually one defines the following notion.

Definition 2.3.2. A subset S of $\mathrm{Fl}(\mathcal{E})$ is said to admit a left calculus of fractions if the following conditions hold:

(a') The identity arrows of $\mathcal{E}$ belong to S.

(b') The composite of two arrows belonging to S belongs to S.

(c') Every diagram of type $(D_1)'$ below, in which s belongs to S, can be completed to a diagram of type $(D_2)'$, in which t belongs to S:

$$(D_1)' \qquad \begin{array}{ccc} X' & \xrightarrow{u'} & Y' \\ {\scriptstyle s}\downarrow & & \\ X & & \end{array} \qquad (D_2)' \qquad \begin{array}{ccc} X' & \xrightarrow{u'} & Y' \\ {\scriptstyle s}\downarrow & & \downarrow{\scriptstyle t} \\ X & \xrightarrow[u]{} & Y. \end{array}$$

(d') For every commutative diagram Δ of the form below, in which s belongs to S, there exists a morphism t with source Y and belonging to S such that $t \circ f = t \circ g$:

$$(\Delta) \qquad X' \xrightarrow{s} X \underset{g}{\overset{f}{\rightrightarrows}} Y.$$

2.3.3

Suppose that S is a subset of $\mathrm{Fl}(\mathcal{E})$ admitting a right calculus of fractions. It follows from part (d) of 2.3.1 that, for every object X of $\mathcal{E}$, the category $(S/X)^\circ$, opposite to the category of arrows over X belonging to S, is filtering (SGA 4 I 2.7). Consider then the category $\mathcal{E}_S$ described as follows:

- the objects of $\mathcal{E}_S$ are the objects of $\mathcal{E}$;
- if X and Y are two objects of $\mathcal{E}$,

$$\mathrm{Hom}_{\mathcal{E}_S}(X, Y) = \varinjlim_{(S/X)^\circ} \mathrm{Hom}_{\mathcal{E}}(\mathrm{source}(\cdot), Y).$$

If P_S denotes the evident functor from $\mathcal{E}$ to $\mathcal{E}_S$, the pair $(P_S, \mathcal{E}_S)$ is a solution of the universal problem described at the beginning of the paragraph. In this case we agree to write $\mathcal{E}(S^{-1})$ for this particular solution.

2.3.4

Let now S be a subset of $\mathrm{Fl}(\mathcal{E})$ admitting a left calculus of fractions. Then the functor $P_S : \mathcal{E} \to \mathcal{E}(S^{-1})$ commutes with finite inductive limits. In particular, if $\mathcal{E}$ is additive, $\mathcal{E}(S^{-1})$ is additive and P_S is an additive functor.

2.3.5

If $\mathcal{E}$ is an abelian category and if S is a subset of $\mathrm{Fl}(\mathcal{E})$ admitting both a right calculus of fractions and a left calculus of fractions, the category $\mathcal{E}(S^{-1})$ is abelian and the functor P_S is exact. Moreover, the pair $(P_S, \mathcal{E}(S^{-1}))$ is a quotient of $\mathcal{E}$ by the thick abelian subcategory $P_S^{-1}(0)$.

2.4. The category $P_{AR} = \mathrm{Hom}_{AR}(\mathbb{N}^\circ, \mathcal{C})$

Returning to the notation of 2.1, let AR be the set of canonical arrows (cf. 2.1)

$$v_{rX} : X[r] \longrightarrow X,$$

where X runs through the set of objects of P and r through the set of integers ≥ 0.

Proposition 2.4.1. The subset AR of $\mathrm{Fl}(P)$ admits both a right calculus of fractions and a left calculus of fractions.

Proof. The parts (a) $\Rightarrow$ (a') and (b) $\Rightarrow$ (b') of 2.3.1 and 2.3.2 are clear.

We prove (c). Let (D_1) be the commutative diagram below, in which v_{rY} denotes the canonical arrow from $Y[r]$ to Y:

$$\begin{array}{ccc} & & Y[r] \\ & & \downarrow{\scriptstyle v_{rY}} \\ X & \longrightarrow & Y. \end{array}$$

The diagram (D_2) below is commutative, and v_{rX}, the canonical morphism from $X[r]$ to X, belongs to AR, whence the assertion:

$$\begin{array}{ccc} X[r] & \xrightarrow{u[r]} & Y[r] \\ {\scriptstyle v_{rX}}\downarrow & & \downarrow{\scriptstyle v_{rY}} \\ X & \xrightarrow[u]{} & Y. \end{array}$$

We prove (d). Let a commutative diagram be given:

$$X \underset{g}{\overset{f}{\rightrightarrows}} Z[r] \xrightarrow{v_{rZ}} Z.$$

Applying translation by r, one obtains a commutative diagram

$$X[r] \underset{g[r]}{\overset{f[r]}{\rightrightarrows}} Z[2r] \xrightarrow{v_{rZ}[r]} Z[r].$$

It is clear that the following diagram is commutative, so that $f \circ v_{rX} = g \circ v_{rX}$:

$$\begin{array}{ccc} X[r] & \underset{g[r]}{\overset{f[r]}{\rightrightarrows}} & Z[2r] \\ {\scriptstyle v_{rX}}\downarrow & & \downarrow{\scriptstyle v_{rZ}[r]} \\ X & \underset{g}{\overset{f}{\rightrightarrows}} & Z[r]. \end{array}$$

We prove (c'). First observe that, if Y denotes an object of P and r a positive integer, there exists an object T of P such that $Y = T[r]$ and such that, for every object X of P, the homomorphism given by translation by r

$$\mathrm{Hom}_P(X, T) \longrightarrow \mathrm{Hom}_P(X[r], Y)$$

is a bijection. The projective system (T_n, w_n) defined as follows plainly works. If $Y = (Y_n, u_n)_{n\geq 0}$, then T_n is the zero object of $\mathcal{C}$ for $n \geq r-1$ and is Y_{n-r} otherwise, and

$$w_n = 0 \quad \text{for } n \geq r-1, \qquad w_n = u_{n-r}.$$

This said, suppose a diagram of the following type is given, and show that it can be completed as indicated in the statement of (c'):

$$\begin{array}{ccc} X[r] & \xrightarrow{u'} & Y' \\ {\scriptstyle v_{rX}}\downarrow & & \\ X. & & \end{array}$$

For this, let Y be a projective system such that $Y' = Y[r]$ and such that the canonical map

$$\mathrm{Hom}_P(X, Y) \longrightarrow \mathrm{Hom}_P(X[r], Y')$$

is a bijection. Then it is clear that the following diagram is commutative, where u denotes the unique morphism from X to Y such that $u' = u[r]$:

$$\begin{array}{ccc} X[r] & \xrightarrow{u'} & Y' = Y[r] \\ {\scriptstyle v_{rX}}\downarrow & & \downarrow{\scriptstyle v_{rY}} \\ X & \xrightarrow[u]{} & Y. \end{array}$$

We prove (d'). Consider the commutative diagram below, and show that there exists a morphism w from Y such that $w \circ f = w \circ g$:

$$X[r] \xrightarrow{v_{rX}} X \underset{g}{\overset{f}{\rightrightarrows}} Y.$$

It is first of all clear that the following diagram is commutative:

$$\begin{array}{ccc} X[r] & \underset{g[r]}{\overset{f[r]}{\rightrightarrows}} & Y[r] \\ {\scriptstyle v_{rX}}\downarrow & & \downarrow{\scriptstyle v_{rY}} \\ X & \underset{g}{\overset{f}{\rightrightarrows}} & Y. \end{array}$$

In particular $v_{rY} \circ f[r] = v_{rY} \circ g[r]$. Let now T be the system associated to Y and r as at the beginning of the proof of (c'), so that in particular $Y = T[r]$. The translates by r of the morphisms $v_{rT} \circ f$ and $v_{rT} \circ g$ are respectively equal to $v_{rY} \circ f$ and $v_{rY} \circ g[r]$, hence are equal. It follows from the fact that translation by r is injective on morphisms from X to T that the equality below holds, whence the assertion:

$$v_{rT} \circ f = v_{rT} \circ g.$$

Definition 2.4.2. Let $\mathcal{C}$ be an abelian category. The category of projective systems of $\mathcal{C}$ up to translation, denoted $\mathrm{Hom}_{AR}(\mathbb{N}^\circ, \mathcal{C})$, is the category described as follows:

(i) The objects of $\mathrm{Hom}_{AR}(\mathbb{N}^\circ, \mathcal{C})$ are the objects of $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$.

(ii) If X and Y are two objects of $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$, a morphism from X to Y in the category $\mathrm{Hom}_{AR}(\mathbb{N}^\circ, \mathcal{C})$ is an element of the set

$$\mathrm{Hom}_{AR}(X, Y) = \varinjlim_r \mathrm{Hom}(X[r], Y),$$

where, for every pair (r, s) of integers with $s \geq r$, the map

$$\mathrm{Hom}(X[r], Y) \longrightarrow \mathrm{Hom}(X[s], Y)$$

comes from the canonical morphism

$$X[s] \longrightarrow X[r].$$

The composition of morphisms is defined in the evident way.

In what follows, the category $\mathcal{C}$ being fixed, we put, to simplify notation,

$$P = \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C}), \qquad P_{AR} = \mathrm{Hom}_{AR}(\mathbb{N}^\circ, \mathcal{C}).$$

2.4.3

We have seen (2.4.1) that the subset AR of $\mathrm{Fl}(P)$ admits a right calculus of fractions. This allows us (2.3.3) to consider the category

$$P'_{AR} = P(AR^{-1}),$$

which, recall, has the same objects as P. Let X and Y be two objects of P, and denote by $\mathrm{Hom}'_{AR}(X, Y)$ the set of isomorphisms from X to Y in P'_{AR}. An element of $\mathrm{Hom}_{AR}(X, Y)$ defines in the evident way an element of $\mathrm{Hom}'_{AR}(X, Y)$. More precisely, one thus defines a functor

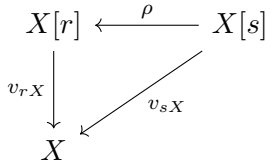
$$m : P_{AR} \longrightarrow P'_{AR}.$$

Proposition 2.4.3. The functor m is an isomorphism of categories.

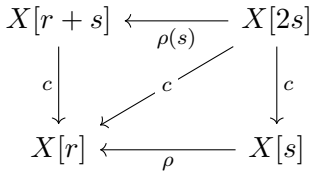
Proof. We must see that, for every pair (X, Y) of objects of P, the corresponding map

$$m_{XY} : \mathrm{Hom}_{AR}(X, Y) \longrightarrow \mathrm{Hom}'_{AR}(X, Y)$$

is a bijection. It is plainly a surjection. For injectivity, one is immediately reduced to seeing that, for every commutative diagram of the type below, there exists an integer t greater than or equal to r and s such that the composite of ρ and the canonical morphism from $X[t]$ to $X[s]$ is the canonical morphism from $X[t]$ to $X[r]$:



But this follows from commutativity of the diagram below, in which the letter c denotes all canonical morphisms involved:



Proposition 2.4.4.

(i) The category P_{AR} is abelian.

(ii) The functor $p_{AR} : P \to P_{AR}$ is exact.

(iii) For an object X of P to be AR-null, it is necessary and sufficient that $p_{AR}(X) = 0$.

(iv) The pair (p_{AR}, P_{AR}) is a quotient of the abelian category P by the thick abelian subcategory of AR-null objects.

Proof. If (iii) is admitted, the other assertions are consequences of (2.3.5). It follows from (2.3.4) that, for an object X of P to be AR-null, it is necessary and sufficient that $p_{AR}(\mathrm{id}_X) = 0$, whence (iii).

Corollary 2.4.5. Let $u : X \to Y$ be a morphism in the category P. The following assertions are equivalent:

(i) $p_{AR}(u)$ is an isomorphism.

(ii) The kernel and cokernel of u are AR-null.

A morphism $u : X \to Y$ in the category P of projective systems, satisfying the equivalent conditions (i) and (ii), will be called an AR-isomorphism.

Definition 2.4.6. Two objects X and Y of the category P are called AR-isomorphic if $p_{AR}(X)$ and $p_{AR}(Y)$ are isomorphic in the category P_{AR}. If X and Y are two AR-isomorphic objects of the category P, there need not exist in general an AR-isomorphism u from X to Y.

2.5. Characterization of projective systems satisfying the Mittag-Leffler-Artin-Rees condition

Proposition 2.5.1. The following assertions for an object X of P are equivalent:

(i) X satisfies (MLAR) (2.1.1).

(ii) There exists a strict projective system Y and an AR-isomorphism $u : Y \to X$ (2.4.5).

(iii) There exists a strict projective system Y such that X and Y are isomorphic in the category P_{AR}.

(iv) X satisfies the Mittag-Leffler condition and, denoting by X' the projective system of universal images of X, the projective system X/X' is AR-null.

Proof. We shall prove the chain of implications

$$(i) \Rightarrow (iv) \Rightarrow (iii) \Rightarrow (ii) \Rightarrow (i).$$

$(i) \Rightarrow (iv)$. There exists an integer m such that the canonical morphism w_{mX} from $X[m]$ to X factors through the canonical inclusion i of X' in X. It follows that $p_{AR}(i)$ is a direct epimorphism and therefore, since p_{AR} is exact, that $p_{AR}(X/X') = 0$. We conclude by (2.4.4) (iii).

$(iv) \Rightarrow (iii)$. Condition (iv) means, with the preceding notation, that $p_{AR}(i)$ is an epimorphism. But because p_{AR} is exact, it is also a monomorphism, hence an isomorphism. For Y one takes the projective system X'.

$(iii) \Rightarrow (ii)$. The P_{AR}-isomorphism from Y to X whose existence is assumed is the image under p_{AR} of a P-morphism $Y[r] \to X$, where r denotes a positive or zero integer. The conclusion follows from the fact that $Y[r]$ is strict.

$(ii) \Rightarrow (i)$. We may suppose Y contained in X and u the canonical injection. Let T be the cokernel of u. The hypothesis means that T is AR-null, hence there exists an integer r such that, for every $s \geq r$, the canonical morphism from $T[s]$ to T is zero. It follows that, for $s \geq r$, the image of $X[s]$ in X is contained in Y; since it also plainly contains the image, equal to Y, of $Y[s]$ in Y, it is equal to Y. Thus Y is the image of $X[s]$ for s sufficiently large, whence X satisfies (MLAR), and Y is the projective system of universal images of X.

Corollary 2.5.2. Let $u : Y \to X$ be an AR-isomorphism, with Y strict. Under these conditions, X satisfies (MLAR) and $u(Y)$ is the projective system of universal images of X.

3. J-adic and AR-J-adic projective systems

Let A be a commutative ring with unit, let J be an ideal of A, and let $(\mathcal{C}, \rho)$ be an abelian A-category. We suppose either that J is of finite type, or that $\mathcal{C}$ has infinite direct sums. The notation is the same as in the preceding paragraph. In particular, the symbols P and P_{AR} denote respectively the categories $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$ and $\mathrm{Hom}_{AR}(\mathbb{N}^\circ, \mathcal{C})$.

3.1. J-adic projective systems

Definition 3.1.1. Let X be an object of P. It is called J-adic if it satisfies the following conditions:

(i) for every integer $n \geq 0$, $J^{n+1}X_n = 0$;

(ii) for every pair (m, n) of integers with $m \geq n \geq 0$, the morphism

$$A/J^{n+1} \otimes_A X_m \longrightarrow X_n$$

deduced from the transition morphism $X_m \to X_n$ is an isomorphism.

We shall write J-ad($\mathcal{C}$) for the full subcategory of P generated by the J-adic projective systems.

Remark 3.1.2

Let I and J be two ideals of A and suppose either that I and J are of finite type, or that $\mathcal{C}$ has infinite direct sums. Then one can show that, if I and J define the same topology on A, the categories I-ad($\mathcal{C}$) and J-ad($\mathcal{C}$) are equivalent.

Proposition 3.1.3 (Stability under exact sequences). Let

$$0 \longrightarrow X \xrightarrow{u} Y \xrightarrow{v} Z \longrightarrow 0$$

be an exact sequence of P.

(i) If X is strict and Y is J-adic, then Z is J-adic.

(ii) If Y is strict and Z is J-adic, then X is strict.

(iii) If X and Z are J-adic, then Y is J-adic.

Proof. If $m \geq n$, it is clear that the diagram (T) below, in which the vertical arrows denote the transition morphisms, is commutative and exact:

$$\begin{array}{ccccccccc} & & A/J^{n+1} \otimes_A X_m & \xrightarrow{\mathrm{id} \otimes u_m} & A/J^{n+1} \otimes_A Y_m & \xrightarrow{\mathrm{id} \otimes v_m} & A/J^{n+1} \otimes_A Z_m & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle f_{nm}} & & \downarrow{\scriptstyle g_{nm}} & & \downarrow{\scriptstyle h_{nm}} & & \\ 0 & \longrightarrow & X_n & \longrightarrow & Y_n & \longrightarrow & Z_n & \longrightarrow & 0. \end{array}$$

In case (i), f_{nm} is an epimorphism and g_{nm} an isomorphism. In case (ii), g_{nm} is an epimorphism and h_{nm} an isomorphism. In case (iii), f_{nm} and h_{nm} are isomorphisms. In all three cases, the snake lemma applied to the diagram (T) gives the conclusion.

3.2. AR-J-adic projective systems

Proposition 3.2.1. The following assertions, for an object X of P such that $J^{n+1}X_n = 0$ for every $n \geq 0$, are equivalent:

(i) There exists a J-adic projective system Y and an AR-isomorphism $u : Y \to X$ (2.4.5).

(ii) There exists a J-adic projective system Y, isomorphic to X in the category P_{AR}.

Proof. We have to show that (ii) implies (i). A P_{AR}-isomorphism from Y to X is represented, for some integer r, by an AR-isomorphism $v : Y[r] \to X$. Since $J^{n+1}X_n = 0$ for every $n \geq 0$ and Y is J-adic, v is the composite of a P-morphism $u : Y \to X$ and the canonical morphism from $Y[r]$ to Y. It is then clear that u is an AR-isomorphism, whence the assertion.

Definition 3.2.2. A projective system indexed by $\mathbb{N}$ with values in $\mathcal{C}$ is called AR-J-adic if:

(a) $J^{n+1}X_n = 0$ for every $n \geq 0$;

(b) it satisfies the equivalent conditions (i) and (ii) of Proposition 3.2.1.

Proposition 3.2.3. Let X be a projective system indexed by $\mathbb{N}$ with values in $\mathcal{C}$. Suppose that $J^{n+1}X_n = 0$ for every $n \geq 0$. Then, in order that X be AR-J-adic, it is necessary and sufficient that it satisfy (MLAR) and that, denoting by X' its projective system of universal images, there exist an integer $r \geq 0$ such that, for every pair (m, n) of integers with $m \geq n + r$, the "transition morphism" below is an isomorphism:

$$X'_m/J^{n+1}X'_m \longrightarrow X'_{n+r}/J^{n+1}X'_{n+r}.$$

Proof.

(a) The conditions of the statement are sufficient. If X satisfies (MLAR), it is AR-isomorphic to its projective system of universal images X'. Moreover, the hypothesis made on X' means that the projective system

$$\left(X'_{n+r}/J^{n+1}X'_{n+r}\right)_{n\geq 0},$$

with the evident transition morphisms, is J-adic. It is clear that this projective system is AR-isomorphic (2.4.6) to X'.

(b) The conditions of the statement are necessary. If X is AR-J-adic, it is AR-isomorphic to a strict projective system, hence satisfies (MLAR). The projective system X' of universal images of X is AR-isomorphic to X, hence is AR-J-adic. To prove the second point, it remains to see that, if X is a strict AR-J-adic projective system, there exists an integer r such that the projective system $\ell_r(X)$ defined by

$$\ell_r(X)_n = X_{n+r}/J^{n+1}X_{n+r}$$

is J-adic. For this, let $u : Y \to X$ be an AR-isomorphism, with Y J-adic. Since the kernel T of u is AR-null, let r be an integer such that the canonical morphism $T[r] \to T$ is zero. It is immediate that the canonical morphism

$$\ell_r(u) : \ell_r(Y) \longrightarrow \ell_r(X)$$

is an isomorphism, whence the assertion.

Proposition 3.2.4 (Stability under exact sequences). Let

$$0 \longrightarrow X \xrightarrow{u} Y \xrightarrow{v} Z \longrightarrow 0$$

be an exact sequence of P, the projective systems X, Y, and Z being such that

$$J^{n+1}X_n = J^{n+1}Y_n = J^{n+1}Z_n = 0 \qquad (n \geq 0).$$

(i) If X satisfies (MLAR) and Y is AR-J-adic, then Z is AR-J-adic.

(ii) If Y satisfies (MLAR) and Z is AR-J-adic, then X satisfies (MLAR).

Proof. We use freely, for every projective system X and every integer r, the notation $\ell_r(X)$ already made explicit.

Proof of (i). If X' and Y' denote the projective systems of universal images of X and Y, then u maps X' into Y', whence the evident exact commutative diagram below, in which the arrows are evident:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & X' & \longrightarrow & Y' & \longrightarrow & \widetilde{Z'} & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & X & \longrightarrow & Y & \longrightarrow & Z & \longrightarrow & 0. \end{array}$$

Since the category P_{AR} is abelian and the functor $P \to P_{AR}$ is exact, it follows from this diagram, and from the fact that the inclusions of X' and Y' into X and Y respectively are AR-isomorphisms (2.5.1), that the morphism $\widetilde{Z} \to Z$ is an AR-isomorphism.

This allows us to reduce to the case where X and Y, and therefore Z, are strict. Then there exists an integer r such that the projective system $\ell_r(Y)$ is J-adic. The functor ℓ_r is plainly right exact, whence an exact sequence

$$\ell_r(X) \xrightarrow{\ell_r(u)} \ell_r(Y) \xrightarrow{\ell_r(v)} \ell_r(Z) \longrightarrow 0.$$

After replacing $\ell_r(X)$ by its image under $\ell_r(u)$, we are under the hypotheses for applying (3.1.3 (i)), which shows that $\ell_r(Z)$ is J-adic, whence the assertion.

(ii) Let Y' and Z' be the projective systems of universal images of Y and Z. Consider the evident exact commutative diagram below, in which the two vertical arrows on the right are the canonical inclusions:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \widetilde{X} & \longrightarrow & Y' & \longrightarrow & Z' & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & X & \xrightarrow[u]{} & Y & \xrightarrow[v]{} & Z & \longrightarrow & 0. \end{array}$$

It shows that the morphism $\widetilde{X} \to X$ is an AR-isomorphism, which allows us to reduce to the case where Y and Z are strict. In this case, since Z is strict and AR-J-adic, it follows from 3.2.3 that there exists an integer r such that $\ell_r(Z)$ is J-adic. Considering the exact commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \widetilde{\widetilde{X}} & \longrightarrow & \ell_r(Y) & \longrightarrow & \ell_r(Z) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & X & \xrightarrow[u]{} & Y & \xrightarrow[v]{} & Z & \longrightarrow & 0, \end{array}$$

in which, as before, $\widetilde{\widetilde{X}} \to X$ is an AR-isomorphism, allows us to reduce to the case where Y is strict and Z is J-adic. Then (3.1.3 (ii)) gives the conclusion.

4. Filtrations and graduations

4.1. Generalities

4.1.1

Let $\mathcal{C}$ be an abelian category and let $X = (X_n)_{n\in\mathbb{Z}}$ be a projective system indexed by $\mathbb{Z}$ with values in $\mathcal{C}$. Suppose that

$$X_i = 0 \quad (i < 0).$$

For every element p of $\mathbb{Z}$, define a subobject F^pX of X in the category $P_1 = \mathrm{Hom}(\mathbb{Z}^\circ, \mathcal{C})$ by setting

$$(F^pX)_n = F^pX_n = \begin{cases} \mathrm{Ker}(X_n \to X_{p-1}), & n \geq p-1, \\ 0, & n < p-1, \end{cases}$$

with the transition morphisms defined in the evident way. Thus one obtains a decreasing filtration $(F^pX)_{p\in\mathbb{Z}}$ of X satisfying

$$F^pX = X \quad \text{if } p \leq 0, \tag{a}$$

$$(F^pX)_{p-1} = 0 \quad \text{for all } p. \tag{b}$$

Moreover, the snake lemma applied to the exact commutative diagram (D) below proves that, as soon as $n \geq p$, the canonical morphism

$$F^pX_n/F^{p+1}X_n \longrightarrow \mathrm{Im}(X_n \to X_p) \cap \mathrm{Ker}(X_p \to X_{p-1})$$

is an isomorphism:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{Ker}(X_n \to X_p) & \longrightarrow & X_n & \longrightarrow & \mathrm{Im}(X_n \to X_p) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & 0 & \longrightarrow & X_{p-1} & \xrightarrow{\sim} & X_{p-1} & \longrightarrow & 0. \end{array}$$

If now X is a projective system indexed by $\mathbb{N}$ with values in $\mathcal{C}$, we extend it to a projective system indexed by $\mathbb{Z}$ by putting $X_n = 0$ for $n < 0$, with the evident transition morphisms, which allows the preceding constructions to be applied to it. This allows us also to consider the category

$$P = \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$$

as a full subcategory of P_1.

Definition 4.1.2. Let X be a projective system indexed by $\mathbb{Z}$. We say that X is essentially constant if there exists an integer p such that, for every pair (r, s) of integers greater than or equal to p and satisfying $s \geq r$, the transition morphism

$$X_s \longrightarrow X_r$$

is an isomorphism. It is clear that it is enough to require this when $r = p$.

Proposition 4.1.3 (The property (MLAR) and associated gradeds). The following assertions for an object X of the category P are equivalent:

(i) X satisfies (MLAR).

(ii) The projective system with values in the category of objects of $\mathcal{C}$ graded by $\mathbb{N}$,

$$r \longmapsto (\mathrm{gr}^{\alpha}(X_{\alpha+r}))_{\alpha\in\mathbb{N}},$$

with the evident transition morphisms, is essentially constant.

(iii) The projective system with values in the category of objects of $\mathcal{C}$ graded by $\mathbb{N}$,

$$n \longmapsto (\mathrm{gr}^{p}(X_n))_{p\in\mathbb{N}},$$

with the evident transition morphisms, satisfies (MLAR).

Proof. $(i) \Rightarrow (ii)$ follows from the expression of $F^pX_n/F^{p+1}X_n$ given in 4.1.1.

$(ii) \Rightarrow (iii)$. Let r be an integer such that, for every $s > r$ and every p, the canonical morphism

$$\mathrm{gr}^{p}(X_{p+s}) \longrightarrow \mathrm{gr}^{p}(X_{p+r})$$

is an isomorphism. We shall see that, for every pair (m, n) of integers with $m \geq n + r$, the equality below is satisfied for every integer p:

$$\mathrm{Im}(\mathrm{gr}^{p}(X_m) \to \mathrm{gr}^{p}(X_n)) = \mathrm{Im}(\mathrm{gr}^{p}(X_{n+r}) \to \mathrm{gr}^{p}(X_n)).$$

Indeed:

(a) If $p \geq n + 1$, then $\mathrm{gr}^{p}(X_n) = 0$,

(b) if $p \leq n$, the chain of inequalities $m \geq n + r \geq p + r$ shows that the canonical morphism

$$\mathrm{gr}^{p}(X_m) \longrightarrow \mathrm{gr}^{p}(X_{n+r})$$

is an isomorphism, whence the assertion.

$(iii) \Rightarrow (i)$. Denote by Y the projective system of (iii), and let r be an integer such that

$$\mathrm{Im}(Y[s] \to Y) = \mathrm{Im}(Y[r] \to Y) \qquad (s \geq r).$$

If n and ℓ are two integers, with $\ell \geq n$, the filtration induced on $\mathrm{Im}(X_\ell \to X_n)$ by that of X_n is also the "quotient" filtration of that of X_ℓ, and consequently, endowing $\mathrm{Im}(X_\ell \to X_n)$ with this filtration, the equality below is satisfied:

$$\mathrm{gr}^{p}(\mathrm{Im}(X_\ell \to X_n)) = \mathrm{Im}(\mathrm{gr}^{p}(X_\ell) \to \mathrm{gr}^{p}(X_n)).$$

In particular, condition (iii) is expressed by saying that, as soon as $\ell \geq n + r$, the canonical monomorphism

$$j : \mathrm{Im}(X_\ell \to X_n) \longrightarrow \mathrm{Im}(X_{n+r} \to X_n)$$

induces an isomorphism on associated gradeds. Since the gradings are finite, it follows that j itself is an isomorphism, whence (i).

4.1.4

If X is an object of $\mathcal{P}$ satisfying (ML), it follows from the expression of the associated graded recalled in (4.1.1) that, for every integer p, the projective system

$$\mathrm{gr}^p(X) = \left(\mathrm{gr}^p(X_n)\right)_{n\in\mathbb{N}}$$

is essentially constant.

Its projective limit, which exists without any hypothesis on the abelian category $\mathcal{C}$, will be called the p-th component of the strict associated graded of X, and will be denoted

$$\mathrm{grs}^p(X).$$

4.2. Projective systems adapted to J and the Artin-Rees lemma

We suppose given a commutative ring A, an ideal J of A, and an abelian A-category $\mathcal{C}$.

Definition 4.2.1. An object X of the category $\mathcal{P} = \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$ is said to be adapted to J if its filtration $(F^pX)_{p\in\mathbb{N}}$ as a projective system (4.1.1) is compatible with the J-adic filtration of X, i.e. if for every pair (p, q) of non-negative integers the inclusion below holds:

$$J^pF^q(X) \subset F^{p+q}(X).$$

Lemma 4.2.2. Let X be an object of the category $\mathcal{P}$. The following assertions are equivalent:

(i) X is adapted to J.

(ii) For every pair (n, p) of integers with $p \leq n + 1$, one has

$$J^pF^{n-p+1}(X_n) = 0.$$

Proof. $(i) \Rightarrow (ii)$: then

$$J^pF^{n-p+1}(X_n) \subset F^{n+1}(X_n) = 0.$$

$(ii) \Rightarrow (i)$: if $n < p + q$, $F^{p+q}(X_n) = 0$ by definition. Moreover

$$J^pF^q(X_n)$$

is contained in $J^{n+1-q}F^q(X_n)$, and the latter is zero by hypothesis. If $n > p + q$, the image of $J^pF^q(X_n)$ in X_{p+q-1} under the transition morphism is contained in $J^pF^q(X_{p+q-1})$, which is zero by hypothesis. The inclusion

$$J^pF^q(X_n) \subset F^{p+q}(X_n)$$

therefore follows by definition of the filtration of a projective system.

In particular, it follows from (4.2.2) that every projective subsystem of a projective system adapted to J is adapted to J.

Examples. a) A J-adic projective system is adapted to J. It follows that every projective subsystem of a J-adic projective system is adapted to J.

b) If a projective system X satisfies condition (ML) and is adapted to J, then its projective system of universal images is also adapted to J.

4.2.3. The associated graded of a projective system adapted to J

Let X be a projective system adapted to J. Since the filtration of X is compatible with J, it is clear that the graded object

$$\left(\mathrm{gr}^p(X)\right)_{p\in\mathbb{N}}$$

is canonically endowed with the structure of a graded $\mathrm{gr}_J(A)$-module. In particular, by passage to the limit, one deduces that when X satisfies condition (ML), the graded object

$$\mathrm{grs}(X) = \left(\mathrm{grs}^p(X)\right)_{p\in\mathbb{N}}$$

is canonically endowed with the structure of a graded $\mathrm{gr}_J(A)$-module.

Let us briefly spell out how, when moreover X is strict, one defines the corresponding morphisms:

$$\omega_{pq} : J^p/J^{p+1} \otimes_A F^q(X_q) \longrightarrow F^{p+q}(X_{p+q}).$$

Since the projective system X is strict, we know (4.1.1 and 4.1.2) that the following canonical morphism is an isomorphism:

$$\varphi : F^q(X_{p+q})/F^{q+1}(X_{p+q}) \longrightarrow F^q(X_q).$$

Moreover, the fact that the filtration of X is adapted to J gives a morphism

$$J^p \otimes_A F^q(X_{p+q}) \longrightarrow F^{p+q}(X_{p+q})$$

which factors, since

$$J^{p+1}F^q(X_{p+q}) \subset F^{p+q+1}(X_{p+q}) = 0, \qquad J^pF^{q+1}(X_{p+q}) \subset F^{p+q+1}(X_{p+q}) = 0,$$

through

$$J^p/J^{p+1} \otimes_A \left(F^q(X_{p+q})/F^{q+1}(X_{p+q})\right)$$

as a morphism

$$\beta : (J^p/J^{p+1}) \otimes_A \left(F^q(X_{p+q})/F^{q+1}(X_{p+q})\right) \longrightarrow F^{p+q}(X_{p+q}).$$

The morphism ω_{pq} is then given by the following expression:

$$\omega_{pq} = \beta \circ (\mathrm{id}_{J^p/J^{p+1}} \otimes_A \varphi)^{-1}.$$

Lemma 4.2.4. Let X be a J-adic projective system. The canonical morphism

$$\mathrm{gr}_J(A) \otimes_A X_0 \longrightarrow \mathrm{grs}(X),$$

coming from the graded $\mathrm{gr}_J(A)$-module structure of $\mathrm{grs}(X)$, is an epimorphism.

Proof. This follows immediately from the description of the morphisms ω_{pq} given in (4.2.3).

Proposition 4.2.5. Characterization of strict AR-J-adic projective systems by means of their associated gradeds. Let X be a strict projective system indexed by $\mathbb{N}$, with values in $\mathcal{C}$. Suppose that for every integer n, one has

$$J^{n+1}X_n = 0.$$

The following assertions are equivalent:

(i) X is AR-J-adic.

(ii) There exists an integer $r > 0$ such that, for every integer n, the following inclusion holds:

$$F^n(X_n) \subset J^{n-r}X_n.$$

(iii) There exists an integer r such that, for every integer m, the following canonical morphism is an isomorphism whenever $n \geq m + r$:

$$\mathrm{gr}^n(J^m X) \longrightarrow \mathrm{gr}^n(X).$$

In the statement of (ii), we agree to set $J^{n-r}X_n = X_n$ for $n < r$.

Proof. The equivalence of (ii) and (iii) is clear, since X and $J^m X$ are strict. Let us prove the equivalence of (i) and (ii). We know (3.2.3) that (i) is equivalent to the existence of an integer r such that, for every pair (m, n) of integers with $m \geq n + r$, the transition morphism below is an isomorphism:

$$X_{m+1}/J^{n+1}X_{m+1} \longrightarrow X_m/J^{n+1}X_m.$$

Consider the following exact commutative diagram:

$$\begin{array}{ccccccccc}
 & & 0 & & 0 & & & & \\
 & & \downarrow & & \downarrow & & & & \\
 & & J^{n+1}X_{m+1} & \longrightarrow & J^{n+1}X_m & \longrightarrow & 0 & & \\
 & & \downarrow & & \downarrow & & & & \\
0 & \longrightarrow & F^{m+1}(X_{m+1}) & \longrightarrow & X_{m+1} & \longrightarrow & X_m & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & & & \\
 & & X_{m+1}/J^{n+1}X_{m+1} & \longrightarrow & X_m/J^{n+1}X_m & \longrightarrow & 0 & & \\
 & & \downarrow & & \downarrow & & & & \\
 & & 0 & & 0. & & & &
\end{array}$$

It shows the existence of a canonical isomorphism between

$$\mathrm{Ker}(X_{m+1}/J^{n+1}X_{m+1} \longrightarrow X_m/J^{n+1}X_m)$$

and

$$F^{m+1}(X_{m+1})/(F^{m+1}(X_{m+1}) \cap J^{n+1}X_{m+1}).$$

In particular, for the transition morphism after reduction modulo J^{n+1} to be an isomorphism, it is necessary and sufficient that $F^{m+1}(X_{m+1})$ be contained in $J^{n+1}X_{m+1}$, which is precisely assertion (ii).

Theorem 4.2.6. Artin-Rees lemma. Let X be a projective system indexed by $\mathbb{N}$, with values in $\mathcal{C}$. Suppose that:

(i) X satisfies (MLAR);

(ii) X is adapted to J;

(iii) $\mathrm{grs}(X)$ is a graded $(\mathrm{gr}_J(A), \mathcal{C})$-module of finite type, i.e. for every increasing sequence $(M_n)_{n\in\mathbb{N}}$ of graded sub-$\mathrm{gr}_J(A)$-modules of $\mathrm{grs}(X)$ whose union is $\mathrm{grs}(X)$, there exists an integer p such that

$$\mathrm{grs}(X) = M_p.$$

Then X is AR-J-adic.

Proof. Recall that if X' is the projective system of universal images of X, we have set

$$\mathrm{grs}(X) = \mathrm{gr}(X').$$

Moreover, X' is adapted to J, so it remains to show that X' is AR-J-adic. Suppose that the following lemma has been proved.

Lemma 4.2.7. Let X be a strict projective system adapted to J. For every integer s, the graded subobject $\big((M_s)_n\big)_{n\in\mathbb{N}}$ of $\mathrm{grs}(X)$ defined by the equalities

$$(M_s)_n = J^{n-s}X_n \cap F^n(X_n) \qquad (J^i = A \text{ if } i < 0),$$

is a graded $\mathrm{gr}_J(A)$-submodule of $\mathrm{grs}(X)$.

To prove the theorem, we may suppose X strict. Then $\mathrm{grs}(X)$ is the union of the increasing sequence of the M_s, hence is equal to one of them. This means that there exists an integer s_0 such that

$$F^n(X_n) \subset J^{n-s_0}X_n$$

for every integer n. We conclude by (4.2.5).

Proof of 4.2.7. Return to the notation of (4.2.3). We have to see that the morphism

$$\omega_{pq} : J^p/J^{p+1} \otimes_A F^q(X_q) \longrightarrow F^{p+q}(X_{p+q})$$

sends

$$J^p/J^{p+1} \otimes_A \big(J^{q-s}X_q \cap F^q(X_q)\big)$$

into

$$J^{p+q-s}X_{p+q} \cap F^{p+q}(X_{p+q}).$$

Now the canonical morphism

$$\rho : X_{p+q}/F^{q+1}(X_{p+q}) \longrightarrow X_q$$

is an isomorphism and sends

$$\big(J^{q-s}X_{p+q} + F^{q+1}(X_{p+q})\big)/F^{q+1}(X_{p+q})$$

onto $J^{q-s}X_q$. It follows that the inverse image under $\mathrm{id}(J^p/J^{p+1}) \otimes_A \varphi$ (4.2.3) of

$$J^p/J^{p+1} \otimes_A \big(J^{q-s}X_q \cap F^q(X_q)\big)$$

is

$$J^p/J^{p+1} \otimes_A \frac{(J^{q-s}X_{p+q} \cap F^q(X_{p+q})) + F^{q+1}(X_{p+q})}{F^{q+1}(X_{p+q})}.$$

It is now clear that the image under β (4.2.3) of this last object is contained in

$$J^{p+q-s}X_{p+q} \cap J^p F^q(X_{p+q}),$$

hence a fortiori in

$$J^{p+q-s}X_{p+q} \cap F^{p+q}(X_{p+q}).$$

This proves the lemma.

5. Noetherian J-adic and AR-J-adic projective systems

Throughout this paragraph, a noetherian commutative ring A, an ideal J of A, and an abelian A-category $\mathcal{C}$ are fixed.

5.1. Generalities

Definition 5.1.1. An object X of the category $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$ is said to be noetherian J-adic (resp. artinian) if it is J-adic and if its components are noetherian (resp. artinian) objects of the category $\mathcal{C}$.

We shall denote by $J\text{-adn}(\mathcal{C})$ (resp. $J\text{-adf}(\mathcal{C})$) the full subcategory of $\mathcal{P} = \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$ whose objects are noetherian (resp. artinian) J-adic projective systems. It is clear (3.1.3) that an extension of noetherian (resp. artinian) J-adic projective systems is of the same type.

Proposition 5.1.2. Let X be a J-adic object of $\mathcal{P}$. In order for X to be noetherian (resp. artinian) J-adic, it is necessary and sufficient that it be J-adic and that X_0 be noetherian (resp. artinian).

Proof. Indeed, let X be a J-adic projective system such that X_0 is noetherian (resp. artinian). Consider the canonical epimorphism (4.2.4):

$$\mathrm{gr}_J(A) \otimes_A X_0 \longrightarrow \mathrm{grs}(X).$$

Since X_0 is noetherian (resp. artinian) and J^n is of finite type for every n, the existence of this epimorphism shows that for every integer n, the kernel of the canonical morphism

$$X_n \longrightarrow X_{n-1}$$

is noetherian (resp. artinian). It follows at once by induction on n that the X_n are noetherian (resp. artinian).

Definition 5.1.3. Let X be a projective system indexed by $\mathbb{N}$, with values in $\mathcal{C}$. It is said to be noetherian (resp. artinian) AR-J-adic if it is AR-J-adic and if its components are noetherian (resp. artinian) objects.

We shall denote by AR-J-adn$(\mathcal{C})$ (resp. AR-J-adf$(\mathcal{C})$) the full subcategory of $\mathrm{Hom}_{\mathrm{AR}}(\mathbb{N}^\circ, \mathcal{C})$ (2.4) generated by the images of noetherian (resp. artinian) AR-J-adic projective systems.

It is then clear that the canonical functors

$$P^n_{\mathrm{AR}} : J\text{-adn}(\mathcal{C}) \longrightarrow \text{AR-}J\text{-adn}(\mathcal{C}),$$

$$P^f_{\mathrm{AR}} : J\text{-adf}(\mathcal{C}) \longrightarrow \text{AR-}J\text{-adf}(\mathcal{C}),$$

obtained by restriction of P_{AR} (2.4), are equivalences of categories.

Let us briefly recall the statement and proof of Hilbert's theorem.

Theorem 5.1.4. Hilbert's theorem. Let A be a commutative ring, $\mathcal{C}$ an abelian A-category, and M an object of finite type (resp. noetherian) of $\mathcal{C}$. For every A-algebra of finite type B, graded by $\mathbb{N}$, the graded $(B,\mathcal{C})$-module

$$B \otimes_A M$$

is of finite type (resp. noetherian).

N.B. If $B = \bigoplus_{n\geq 0} B_n$, then $B \otimes_A M$ denotes the graded object $(B_n \otimes_A M)_{n\in\mathbb{N}}$.

Proof. One reduces immediately to the case where B is the polynomial ring $A[T]$, endowed with its usual grading. The $(B,\mathcal{C})$-module $A[T] \otimes_A M = (M_n)_{n\in\mathbb{N}}$ is then obtained by putting $M_n = M$ for every n, with T sending M_n to M_{n+1} by the identity of M, for every integer n.

Let N be a graded sub-$(A[T],\mathcal{C})$-module of $A[T] \otimes_A M$. The components $(N_n)_{n\in\mathbb{N}}$ of N define an increasing sequence

$$N_0 \subset N_1 \subset \cdots \subset N_n \subset \cdots$$

of subobjects of M. Suppose now that M is noetherian (resp. of finite type), and let

$$N^1 \subset N^2 \subset \cdots \subset N^p \subset \cdots$$

be an increasing sequence of graded sub-$(A[T],\mathcal{C})$-modules of $A[T] \otimes_A M$, whose union, in the first hypothesis, when M is of finite type, is $A[T] \otimes_A M$.

Consider the following double-entry table:

$$\begin{array}{ccccccc}
N^1_0 & \subset & N^2_0 & \subset \cdots \subset & N^p_0 & \subset \cdots \\
\cap & & \cap & & \cap & \\
N^1_1 & & N^2_1 & & N^p_1 & \\
\vdots & & \vdots & & \vdots & \\
\cap & & \cap & & \cap & \\
N^1_n & \subset & N^2_n & \subset \cdots \subset & N^p_n & \subset \cdots .
\end{array}$$

It is clear by hypothesis on M that there exists a pair (p_0, n_0) such that $N^{p_0}_{n_0}$ is maximal (resp. equal to M). If p_1 is an integer $\geq p_0$ such that the $N^{p_1}_n$ $(n \leq n_0)$ are the largest elements of the sequences $(N^p_n)_{p\in\mathbb{N}}$, it is clear that $N^p = N^{p_1}$ as soon as $p \geq p_1$, which allows one to conclude in both cases.

Corollary 5.1.5. Suppose moreover that the category $\mathcal{C}$ has denumerable direct sums. Then for every object M of finite type (resp. noetherian) of $\mathcal{C}$, and every A-algebra of finite type B, the $(B,\mathcal{C})$-module $B \otimes_A M$ is of finite type (resp. noetherian).

Proof. One reduces to the case where $B = A[T]$. Let N be a sub-$(A[T],\mathcal{C})$-module of $A[T] \otimes_A M$, considered as an object of $\mathcal{C}$. We shall denote by $\mathrm{gr}(N)$ the associated graded of N for the

filtration induced by the natural filtration of the graded object $A[T] \otimes_A M$: $\mathrm{gr}(N)$ is a graded sub-$(A[T], \mathcal{C})$-module of the graded $(A[T], \mathcal{C})$-module $A[T] \otimes_A M$.

Now let

$$N^0 \subset N^1 \subset \cdots \subset N^p \subset \cdots$$

be an increasing sequence of sub-$(A[T], \mathcal{C})$-modules of $A[T] \otimes_A M$, whose union is $A[T] \otimes_A M$ in the first hypothesis. In the first hypothesis (M of finite type), there exists an integer i such that $\mathrm{gr}(N^i) = A[T] \otimes_A M$, whence

$$N^i = A[T] \otimes_A M.$$

In the second hypothesis (M noetherian), the sequence of the $\mathrm{gr}(N^i)$ is stationary, hence the sequence of the N^i is stationary as well.

In what follows, Hilbert's theorem will be useful to us especially through the following proposition.

Proposition 5.1.6. Let A be a noetherian commutative ring, J an ideal of A, and $\mathcal{C}$ an abelian A-category. For every noetherian J-adic projective system X (5.1.1), the graded object $\mathrm{grs}(X)$ is a noetherian $(\mathrm{gr}_J(A), \mathcal{C})$-module.

Proof. Since $\mathrm{gr}_J(A)$ is an A-algebra of finite type, Hilbert's theorem (5.1.4) implies that

$$\mathrm{gr}_J(A) \otimes_A X_0$$

is a noetherian graded $(\mathrm{gr}_J(A), \mathcal{C})$-module. The assertion then follows from the existence of the epimorphism (4.2.4):

$$\mathrm{gr}_J(A) \otimes_A X_0 \longrightarrow \mathrm{grs}(X).$$

5.2. Structure of J-adn$(\mathcal{C})$ and AR-J-adn$(\mathcal{C})$

In this section, we shall denote by $\mathcal{E}_{\mathcal{C}}$, or by $\mathcal{E}$ if there is no possible confusion, the full subcategory of $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$ whose objects are noetherian AR-J-adic projective systems.

Proposition 5.2.1. The category $\mathcal{E}_{\mathcal{C}}$ is stable under kernels and cokernels in $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$. In other words, $\mathcal{E}_{\mathcal{C}}$ is an abelian category and the inclusion functor

$$\mathcal{E}_{\mathcal{C}} \longrightarrow \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$$

is exact.

Proof. Let $u : X \to Y$ be a morphism of $\mathcal{E}_{\mathcal{C}}$. We shall successively see that the cokernel, the image, and the kernel of u are noetherian AR-J-adic. Of course, the proof that the image of u is noetherian AR-J-adic is only a technical intermediate step.

a) $\mathrm{Coker}(u)$ is noetherian AR-J-adic. Since X satisfies (MLAR) and Y is AR-J-adic, $\mathrm{Coker}(u)$ is AR-J-adic (3.2.4 (i)).

b) $\mathrm{Im}(u)$ is noetherian AR-J-adic. From the exact sequence

$$0 \longrightarrow \mathrm{Im}(u) \longrightarrow Y \longrightarrow \mathrm{Coker}(u) \longrightarrow 0,$$

the assertion will follow from Lemma 5.2.1.1 below.

Lemma 5.2.1.1. Let

$$0 \longrightarrow L \longrightarrow M \longrightarrow N \longrightarrow 0$$

be an exact sequence in the category $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$. If M and N are noetherian AR-J-adic, then L is noetherian AR-J-adic.

Proof. It is plainly enough to see that it is AR-J-adic. One reduces, in the same way as in the proof of (3.2.4), to the case where M and N are strict, and then even noetherian J-adic. In this case, it follows from 3.1.3 (ii) that L is strict. The projective system L is strict, adapted to J, and its associated graded, as a graded subobject of $\mathrm{grs}(M)$, is noetherian: $\mathrm{grs}(M)$, a quotient of $\mathrm{gr}_J(A) \otimes_A M_0$, is noetherian (5.1.6). The assertion then follows from the Artin-Rees lemma (4.2.6).

c) $\mathrm{Ker}(u)$ is noetherian AR-J-adic. It is enough to apply (5.2.1.1) to the evident exact sequence below:

$$0 \longrightarrow \mathrm{Ker}(u) \longrightarrow X \longrightarrow \mathrm{Im}(u) \longrightarrow 0.$$

Proposition 5.2.2. The objects of the abelian category AR-J-adn($\mathcal{C}$) are noetherian.

Proof. One reduces immediately to proving the following. Suppose we have a noetherian J-adic object X, a sequence of noetherian J-adic objects $(Y^n)_{n\in\mathbb{N}}$, and morphisms in $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$

$$v_n : Y^n \longrightarrow X$$

such that

(i) the v_n become monomorphisms in AR-J-adn($\mathcal{C}$);

(ii) for every integer n, v_n factors through v_{n+1} in AR-J-adn($\mathcal{C}$),

then the v_n remain stationary, up to isomorphism, for sufficiently large n, in AR-J-adn($\mathcal{C}$).

Now, to say that v_n factors through v_{n+1} in AR-J-adn($\mathcal{C}$) means that there exists an integer r and a morphism

$$f : Y^n[r] \longrightarrow Y^{n+1}$$

such that, with a denoting the canonical morphism

$$Y^n[r] \longrightarrow Y^n,$$

the following equality holds:

$$v_n \circ a = v_{n+1} \circ f.$$

Since the morphism a is strict, it follows in particular that the image of v_n is contained in that of v_{n+1}. Replacing each Y^n by $\mathrm{Im}(v_n)$, we are reduced to seeing that every increasing sequence of strict projective subsystems of X is stationary. But if $(Z^n)_{n\in\mathbb{N}}$ is such a sequence, then, since $\mathrm{grs}(X)$ is noetherian, the increasing sequence of the $\mathrm{grs}(Z^n)$ is stationary, hence so is the sequence of the Z^n.

Summarizing:

Theorem 5.2.3. The categories J-adn($\mathcal{C}$) and AR-J-adn($\mathcal{C}$) are abelian and noetherian.

As for AR-J-adn($\mathcal{C}$), this is what we have just proved. As for J-adn($\mathcal{C}$), it is equivalent to it.

Proposition 5.2.4. Stability under extension. Let

$$0 \longrightarrow X \longrightarrow Y \longrightarrow Z \longrightarrow 0$$

be an exact sequence in $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$, with $J^{n+1}Y_n = 0$ for every n. Suppose that:

(i) Z is AR-J-adic;

(ii) X is artinian AR-J-adic.

Then Y is AR-J-adic.

Proof. As in the proof of (3.2.4), one reduces to the case where Y and Z are strict and Z is J-adic. Then X is strict by (3.1.3 (ii)). There then exists an integer r such that the projective system $(X_{n+r}/J^{n+1}X_{n+r})_{n\in\mathbb{N}}$ is artinian J-adic. Since X is a quotient of it and is AR-isomorphic to it, we are reduced to proving the following lemma.

Lemma 5.2.4.1. Let

$$0 \longrightarrow T \longrightarrow X \longrightarrow Y \longrightarrow Z \longrightarrow 0$$

be an exact sequence in $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$, with $J^{n+1}Y_n = 0$ for every n. If X is artinian J-adic, Z is J-adic, and T is AR-zero, then Y is AR-J-adic.

Proof. To prove the lemma, we first show that, for every integer n, the evident projective system

$$\left(Y_{n+k}/J^{n+1}Y_{n+k}\right)_{k\in\mathbb{N}}$$

is essentially constant. Let S_n^k denote the kernel of the evident morphism

$$X_{n+k}/J^{n+1}X_{n+k} \longrightarrow Y_{n+k}/J^{n+1}Y_{n+k}.$$

Consider the following evident exact commutative diagram:

$$\begin{array}{ccccccccc}
0 & \longrightarrow & S_n^k & \longrightarrow & X_{n+k}/J^{n+1}X_{n+k} & \longrightarrow & Y_{n+k}/J^{n+1}Y_{n+k} & \longrightarrow & Z_{n+k}/J^{n+1}Z_{n+k} & \longrightarrow & 0 \\
 & & \downarrow & & \sim\downarrow & & \downarrow & & \sim\downarrow & & \\
0 & \longrightarrow & T_n & \longrightarrow & X_n & \longrightarrow & Y_n & \longrightarrow & Z_n & \longrightarrow & 0.
\end{array}$$

With n fixed, the objects S_n^k are identified with subobjects of T_n and form a decreasing sequence. Since T_n is artinian, there exists an integer k_0 such that $S_n^k = S_n^{k_0}$ for every integer $k \geq k_0$; it follows at once that the canonical morphisms

$$Y_{n+k}/J^{n+1}Y_{n+k} \longrightarrow Y_{n+k_0}/J^{n+1}Y_{n+k_0}$$

are isomorphisms.

This being said, denote by Y' the projective system defined by

$$Y'_n = \varprojlim_r Y_{n+r}/J^{n+1}Y_{n+r}$$

on objects, and in the evident way on morphisms. The projective system Y' is J-adic. Moreover, by passage to the limit one obtains an exact commutative diagram of the following type:

$$\begin{array}{ccccccccc} 0 & \to & S & \to & X & \to & Y' & \to & Z & \to & 0 \\ & & \downarrow & & \downarrow \mathrm{id} & & \downarrow & & \downarrow \mathrm{id} & & \\ 0 & \to & T & \to & X & \to & Y & \to & Z & \to & 0. \end{array}$$

Since T is AR-zero, the snake lemma applied to this diagram shows that the evident morphism $Y' \to Y$ is an AR-isomorphism, whence Y is AR-J-adic.

Corollary 5.2.5. Let

$$0 \longrightarrow X \longrightarrow Y \longrightarrow Z \longrightarrow 0$$

be an exact sequence in $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$, with $J^{n+1}Y_n = 0$ for every n. Suppose that:

(i) X is artinian AR-J-adic (resp. artinian and noetherian);

(ii) Z is artinian AR-J-adic (resp. noetherian).

Then Y is artinian AR-J-adic (resp. noetherian).

5.3. Noetherian AR-J-adic projective systems and δ-functors

Let $\mathcal{C}$ and $\mathcal{D}$ be two abelian A-categories, and let $F : \mathcal{C} \to \mathcal{D}$ be an additive functor. The functor F extends in the clear way to a functor, again denoted F,

$$F : \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C}) \longrightarrow \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{D}),$$

which is additive and "commutes with translations".

Proposition 5.3.1. Let $\mathcal{C}$ and $\mathcal{D}$ be two abelian A-categories and

$$T = (T^i)_{i \in \mathbb{N}}$$

an exact A-linear δ-functor from $\mathcal{C}$ to $\mathcal{D}$. Suppose that:

(i) For every noetherian object M of $\mathcal{C}$, annihilated by a power of J, and every integer n, $T^n(M)$ is noetherian.

(ii) For every graded A-algebra B of finite type, annihilated by J, and every noetherian graded $(B, \mathcal{C})$-module N, the graded $(B, \mathcal{D})$-modules $T^n(N)$, $n \in \mathbb{N}$, are noetherian.

Then, for every noetherian AR-J-adic object X of $\mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C})$, the $T^n(X)$ are noetherian AR-J-adic.

Proof. Since the functors T^n commute with translations, it is enough to prove the assertion when X is noetherian J-adic. In that case, since $\mathrm{grs}(X)$ is a noetherian graded $\mathrm{gr}_J(A)$-module (5.1.6), it follows from hypothesis (ii) and from a variant of a corollary of Shih's theorem (cf. Appendix A.3) that for every integer n the following assertions hold:

(a) $T^n(X)$ satisfies (MLAR),

(b) grs $T^n(X)$ is a noetherian graded $(\mathrm{gr}_J(A), \mathcal{D})$-module.

The Artin-Rees lemma (4.2.6) allows us to conclude.

Corollary 5.3.2. The δ-functor

$$T = (T^i)_{i\in\mathbb{N}} : \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{C}) \longrightarrow \mathrm{Hom}(\mathbb{N}^\circ, \mathcal{D})$$

induces an exact A-linear δ-functor

$$\mathcal{E}_\mathcal{C} \longrightarrow \mathcal{E}_\mathcal{D},$$

commuting with translations, and hence, by passage to the quotient, a new exact A-linear δ-functor, again denoted $(T^i)_{i\in\mathbb{N}}$,

$$\text{AR-}J\text{-adn}(\mathcal{C}) \longrightarrow \text{AR-}J\text{-adn}(\mathcal{D}).$$

Appendix: Shih's theorem

The purpose of the present appendix is to give a proof of Shih's theorem in the form used in the proof of (5.3.1). This form being more general than the one appearing in EGA 0_{III}, a direct proof, adapted from that of loc. cit., has proved necessary.

Terminology. Let r_0 be an integer ≥ 1. The datum, for every integer $r \geq r_0$, of a bigraded object

$$E_r = (E_r^{pq})_{p\in\mathbb{Z},\ q\in\mathbb{Z}},$$

endowed with a differential d_r of bidegree $(r, 1-r)$, and, for every r, of an isomorphism

$$H(E_r) \xrightarrow{\sim} E_{r+1},$$

will be called below a spectral filter. The notion of a morphism of spectral filters is defined in the evident way.

A.1. Recollections on the spectral sequences associated with δ-functors

Let $\mathcal{C}$ be an abelian category and X an object of $\mathcal{C}$, endowed with a decreasing filtration $(F^pX)_{p\in\mathbb{Z}}$. For every exact δ-functor T from $\mathcal{C}$ to an abelian category $\mathcal{D}$, the method of "exact couples" (cf., e.g., Maclane, *Homology*, p. 336) makes it possible to describe a spectral sequence

$$E(X): \quad E_1^{pq} = T^{p+q}(F^pX/F^{p+1}X) \Rightarrow E^n = T^n(X),$$

for which the filtration of E^n is defined as follows:

$$F^p(E^n) = \mathrm{Im}(T^n(F^pX) \longrightarrow T^n(X)) = \mathrm{Ker}(T^n(X) \longrightarrow T^n(X/F^pX)).$$

Moreover, if the filtration of X is finite, the spectral sequence so obtained is weakly convergent (EGA 0_{III} 11.1.3).

Functoriality. If $f : X \to Y$ is a morphism of filtered objects of $\mathcal{C}$, one constructs functorially a morphism of spectral sequences

$$E(f) : E(X) \longrightarrow E(Y),$$

coinciding with $T^{p+q}(\mathrm{gr}^p f)$ (resp. $T^n(f)$) on $E_1^{pq}(X)$ (resp. $E^n(X)$). In particular, if $u : X \to X$ is an endomorphism of X such that

$$u(F^pX) \subset F^{p+h}(X)$$

for an integer h independent of p, then $E(u)$ is an endomorphism of bidegree $(h, -h)$ of the spectral filter associated with $E(X)$, commuting with the differentials.

A.2. The case of projective systems

Let now $X = (X_n)_{n\in\mathbb{Z}}$ be a projective system of objects of an abelian category $\mathcal{C}$, such that

$$X_i = 0 \qquad (i < 0).$$

If T denotes an exact δ-functor from $\mathcal{C}$ to an abelian category $\mathcal{D}$, T extends naturally to an exact δ-functor, again denoted T,

$$\mathrm{Hom}(\mathbb{Z}^\circ, \mathcal{C}) \longrightarrow \mathrm{Hom}(\mathbb{Z}^\circ, \mathcal{D}).$$

Thus, endowing X with its natural filtration as a projective system (EGA 0_{III} 13.4.1), one obtains a spectral sequence

$$E(X) = E(X_n)_{n\in\mathbb{Z}},$$

where the $E(X_n)$ denote the spectral sequences associated with T and the X_n endowed with the induced filtration.

Properties of $E(X)$. a) For every integer n, the filtration of the abutment $E^n(X)$ in the spectral sequence $E(X)$ is identical with its natural filtration as a projective system when X is strict.

Indeed, denoting by the letter F (as in A.1) the first filtration and by the letter Φ the second, one has for every integer α:

$$F^pE^n(X)_\alpha = \mathrm{Ker}\big(T^n(X_\alpha) \longrightarrow T^n(X_\alpha/F^pX_\alpha)\big)$$

$$= \begin{cases} 0, & \alpha \le p-1, \\ \mathrm{Ker}\big(T^n(X_\alpha) \longrightarrow T^n(X_{p-1})\big), & \alpha \ge p-1. \end{cases}$$

In both cases one recognizes the expression of $\Phi^pE^n(X)$.

This shows in particular that, for $\beta \ge \alpha \ge p$, the transition morphism

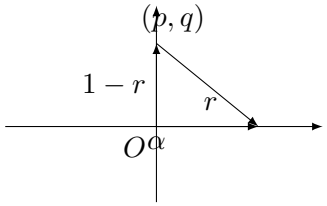
$$E_\infty^{pq}(X_\beta) \longrightarrow E_\infty^{pq}(X_\alpha)$$

which is identified with

$$\mathrm{gr}_T^p\, T^{p+q}(X_\beta) \longrightarrow \mathrm{gr}_T^p\, T^{p+q}(X_\alpha),$$

is a monomorphism, by EGA 0_{III} 13.4.1.3.

b) Fixing $\alpha \in \mathbb{Z}$, it is clear (cf. the adjoining diagram) that, since $F^i(X_\alpha) = 0$ for $i \geq \alpha + 1$, one has:



$$B_r^{pq}(X_\alpha) = B_{r+1}^{pq}(X_\alpha) \quad \text{for } r > p,$$
$$Z_r^{pq}(X_\alpha) = Z_{r+1}^{pq}(X_\alpha) \quad \text{for } r > \alpha - p.$$

c) When X satisfies the Mittag-Leffler condition, the various projective systems $\mathrm{gr}^p(X)$ are essentially constant (EGA 0_{III} 13.4.3). It follows at once that, for $r < +\infty$, the projective systems $E_r^{pq}(X)$ are essentially constant. We shall denote by

$$\mathcal{E}_r^{pq}(X)$$

their projective limits. Since the differential operators pass to the limit, one thus obtains a spectral filter $\mathcal{E}_r^{pq}(X)$, $p, q \in \mathbb{Z}$, $r \geq 1$. The objects

$$\mathcal{Z}_r^{pq}(X), \quad \mathcal{B}_r^{pq}(X) \quad (r < +\infty)$$

associated with this spectral filter are precisely the limits of the essentially constant projective systems $Z_r^{pq}(X)$ and $B_r^{pq}(X)$.

It also follows from part b) that

$$B_\infty^{pq}(X) = B_{p+1}^{pq}(X),$$

which allows one to put

$$\mathcal{B}_\infty^{pq}(X) = \mathcal{B}_{p+1}^{pq}(X).$$

Still supposing that X satisfies (ML), since, for every α,

$$B_r^{pq}(X_\alpha) = B_{r+1}^{pq}(X_\alpha) \qquad (r > p),$$

one has a sequence of canonical monomorphisms

$$\cdots \subset \mathcal{E}_r^{pq}(X) \subset \cdots \subset \mathcal{E}_{p+2}^{pq}(X) \subset \mathcal{E}_{p+1}^{pq}(X). \tag{S}$$

Suppose from now on that X is strict. The following expressions for $Z_r^{pq}(X_n)$ and $B_r^{pq}(X_n)$:

$$Z_r^{pq}(X_n) = \mathrm{Im}\Big[T^{p+q-1}\big(F^{p-r+1}X_n/F^pX_n\big) \xrightarrow{\partial} T^{p+q}\big(F^pX_n/F^{p+1}X_n\big)\Big],$$

$$B_r^{pq}(X_n) = \mathrm{Im}\Big[T^{p+q}\big(F^pX_n/F^{p+r}X_n\big) \longrightarrow T^{p+q}\big(F^pX_n/F^{p+1}X_n\big)\Big],$$

show that

$$\begin{cases} Z_r^{pq}(X_m) \xrightarrow{\sim} Z_r^{pq}(X_n) & \text{for } m \geq n \geq p, \\ B_r^{pq}(X_m) \xrightarrow{\sim} B_r^{pq}(X_n) & \text{for } m \geq n \geq p + r - 1, \end{cases} \tag{d_1}$$

where the canonical morphisms are isomorphisms. In particular, the canonical morphism

$$\mathcal{E}_r^{pq}(X) \longrightarrow E_r^{pq}(X_{p+r-1})$$

is an isomorphism. Moreover, it follows from b) that

$$\begin{cases} Z_\infty^{pq}(X_{p+r-1}) = Z_r^{pq}(X_{p+r-1}) & (r \geq 1), \\ B_\infty^{pq}(X_{p+r-1}) = B_r^{pq}(X_{p+r-1}) & (r > p). \end{cases} \tag{d_2}$$

This makes it possible to define, for every r, a canonical epimorphism

$$\theta_r^{pq} : \mathcal{E}_r^{pq}(X) \longrightarrow E_\infty^{pq}(X_{p+r-1})$$

which is an isomorphism when $r > p$. In addition, if a is an integer such that

$$\mathcal{B}_r^{pq}(X) = \mathcal{B}_a^{pq}(X) \qquad (r \geq a),$$

for example $a = p + 1$ suffices, so that

$$\cdots \hookrightarrow \mathcal{E}_r^{pq}(X) \hookrightarrow \cdots \hookrightarrow \mathcal{E}_{a+1}^{pq}(X) \hookrightarrow \mathcal{E}_a^{pq}(X), \tag{S bis}$$

then, for $s \geq r \geq a$, the diagrams

$$\begin{array}{ccc} \mathcal{E}_s^{pq}(X) & \xrightarrow[\text{epi}]{\theta_s^{pq}} & E_\infty^{pq}(X_{p+s-1}) \\ \downarrow & & \downarrow \text{can} \\ \mathcal{E}_r^{pq}(X) & \xrightarrow[\text{epi}]{\theta_r^{pq}} & E_\infty^{pq}(X_{p+r-1}) \end{array} \tag{d_3}$$

are commutative.

A.3. A variant of Shih's theorem

Suppose given a ring S filtered by ideals $F^i(S)$, $i \geq 0$, acting on X compatibly with its filtration as a projective system.

It follows from the generalities of A.1 that, for every integer i, $\mathrm{gr}^i(S)$ acts on the bigraded objects $E_r(X)$ by morphisms of bidegree $(i, -i)$. In particular, for every integer n,

$$E_r^{(n)}(X) = \left(E_r^{p,q}(X)\right)_{p+q=n}$$

is canonically endowed with the structure of a graded $(\mathrm{gr}^\bullet(S), \mathcal{D})$-module. The same holds by passage to the limit for

$$\mathcal{E}_r^{(n)}(X) = \left(\mathcal{E}_r^{p,q}(X)\right)_{p+q=n}.$$

The ring S, acting on X compatibly with its filtration as a projective system, likewise acts on $T^n(X)$ for every integer n. Consequently, the strict associated graded $\mathrm{grs}(X)$ is canonically endowed with the structure of a graded $(\mathrm{gr}^\bullet(S), \mathcal{C})$-module, and similarly, when $T^n(X)$ satisfies (ML), the strict associated graded $\mathrm{grs}\, T^n(X)$ is canonically endowed with the structure of a graded $(\mathrm{gr}^\bullet(S), \mathcal{D})$-module.

Theorem A.3. Suppose that, for an integer n, the graded $(\mathrm{gr}^\bullet(S), \mathcal{D})$-modules

$$\mathcal{E}_1^{(n)}(X) = T^n(\mathrm{grs}^\bullet X) \quad \text{and} \quad \mathcal{E}_1^{(n-1)}(X) = T^{n-1}(\mathrm{grs}^\bullet X)$$

are noetherian. Then:

(i) $T^n(X)$ satisfies (MLAR);

(ii) grs $T^n(X)$ is a noetherian $(\mathrm{gr}^\bullet(S), \mathcal{D})$-module.

Proof. i) For every pair (m, r) of integers,

$$\mathcal{B}_r^{(m)}(X) = \left(\mathcal{B}_r^{p,m-p}(X)\right)_{p\in\mathbb{N}}$$

is a graded sub-$(\mathrm{gr}^\bullet(S), \mathcal{D})$-module of $\mathcal{E}_1^{(m)}(X)$. In particular, for every integer m, the $\mathcal{B}_r^{(m)}(X)$ form an increasing sequence, indexed by r, of graded sub-$(\mathrm{gr}^\bullet(S), \mathcal{D})$-modules of $\mathcal{E}_1^{(m)}(X)$. Using the fact that $\mathcal{E}_1^{(n)}(X)$ and $\mathcal{E}_1^{(n-1)}(X)$ are noetherian graded $(\mathrm{gr}^\bullet(S), \mathcal{D})$-modules, one deduces that the sequences

$$\left[\mathcal{B}_r^{(n)}(X)\right]_{r\in\mathbb{N}} \qquad \text{and} \qquad \left[\mathcal{B}_r^{(n-1)}(X)\right]_{r\in\mathbb{N}}$$

are stationary.

Thus there exists an integer $a \geq 1$ such that, for every (p, q), with $p + q = n$ or $n - 1$,

$$\mathcal{B}_r^{pq}(X) = \mathcal{B}_a^{pq}(X) \qquad (r \geq a). \tag{A.3.1}$$

Consequently, for $r \geq a + 1$, the arrows d_r with source and target $\mathcal{E}_r^{pq}(X)$, $p + q = n$, are zero. In other words, the monomorphisms

$$\mathcal{E}_s^{pq}(X) \hookrightarrow \mathcal{E}_r^{pq}(X) \qquad (s \geq r \geq a + 1)$$

deduced from (A.3.1) with $p+q = n$ are in fact isomorphisms. For $s \geq r \geq a+1$, the commutativity of diagram (d_3), with $p + q = n$,

$$\begin{array}{ccc} \mathcal{E}_s^{pq}(X) & \xrightarrow[\text{epi}]{\theta_s^{pq}} & E_\infty^{pq}(X_{p+s-1}) \\ \downarrow\sim & & \downarrow \\ \mathcal{E}_r^{pq}(X) & \xrightarrow[\text{epi}]{\theta_r^{pq}} & E_\infty^{pq}(X_{p+r-1}) \end{array}$$

shows that the transition morphism

$$E_\infty^{pq}(X_{p+s-1}) \longrightarrow E_\infty^{pq}(X_{p+r-1}),$$

which is in any case a monomorphism (cf. a)), is an epimorphism, hence an isomorphism. In other words, the projective system

$$r \longmapsto \left[\bigoplus_p \mathrm{gr}^p\, T^n(X_{p+r})\right]_{r\geq 1}$$

is constant from $r = a$ on, and therefore $T^n(X)$ satisfies (MLAR), by (4.1.3).

ii) Denoting by

$$\mathcal{E}_\infty^{(n)}(X), \quad \mathcal{Z}_\infty^{(n)}(X), \quad \mathcal{B}_\infty^{(n)}(X)$$

the "limits" of the various projective systems indexed by r considered above, we see that

$$\mathcal{E}_\infty^{(n)}(X) = \mathcal{Z}_\infty^{(n)}(X)/\mathcal{B}_\infty^{(n)}(X)$$

is a noetherian $(\mathrm{gr}^\bullet(S), \mathcal{D})$-module, since $\mathcal{Z}_\infty^{(n)}(X)$ is contained in $\mathcal{E}_1^{(n)}(X)$. Moreover, it follows from A.2 a) that

$$\mathcal{E}_\infty^{(n)}(X) = \mathrm{grs}\ T^n(X).$$

Exposé VI

ℓ-ADIC COHOMOLOGY

by J.-P. Jouanolou

Throughout this exposé, a prime number ℓ is fixed.

As usual, $X_{\text{ét}}$ denotes the étale site of a prescheme X.

1. Constructible ℓ-adic sheaves

Throughout this paragraph, fix once and for all a locally noetherian prescheme X.

1.1. Definition and generalities

Definition 1.1.1. A constructible ℓ-adic sheaf on X is a projective $(\ell\mathbb{Z})$-adic system of constructible abelian sheaves on $X_{\text{ét}}$ (V 3.2.1).

For a projective $(\ell\mathbb{Z})$-adic system

$$F = (F_n)_{n\in\mathbb{N}}$$

of abelian sheaves on $X_{\text{ét}}$ to be a constructible ℓ-adic sheaf, it is enough that F_0 be constructible. Indeed, the assertion is local and follows, in the noetherian case, from (V 5.1.2).

Let $\mathrm{Abc}(X)$ denote the category of constructible abelian sheaves on X. We shall denote by

$$\ell\text{-}\,\mathrm{adc}(X)$$

the full subcategory of $\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Abc}(X))$ generated by the constructible ℓ-adic sheaves. With the notation of Exposé V,

$$\ell\text{-}\,\mathrm{adc}(X) = (\ell\mathbb{Z})\text{-}\,\mathrm{ad}(\mathrm{Abc}(X)).$$

Letting $\mathrm{Ab}(X)$ denote the category of abelian sheaves on $X_{\text{ét}}$, one knows (SGA 4 IX 2.9) that, when X is noetherian, the constructible abelian sheaves on X are the noetherian abelian sheaves. In this case, the category $\ell\text{-}\,\mathrm{adc}(X)$ is clearly identified with the category denoted

$$(\ell\mathbb{Z})\text{-}\,\mathrm{adn}(\mathrm{Ab}(X))$$

in Exposé V.

Proposition 1.1.2. Let $F = (F_n)_{n\in\mathbb{N}}$ be an object of the category $\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X))$. For F to be constructible ℓ-adic, it is necessary and sufficient that it be so locally for the étale topology of X.

Proof. It is clear that the property of F of being ℓ-adic may be read above a covering of the final object of the site. Moreover, it follows from (SGA 4 IX 2.8) that the F_n are constructible if they are so locally.

Proposition 1.1.3. The category $\ell\text{-}\,\mathrm{adc}(X)$ of constructible ℓ-adic sheaves on X is abelian. It is noetherian when X is noetherian.

Proof. When X is noetherian, the two assertions are consequences of (V 5.2.3). In the general case, one must see that every morphism

$$u : F \longrightarrow G$$

of constructible ℓ-adic sheaves on X has a kernel and a cokernel.

As for the cokernel, this follows from (V 3.1.3). Let us prove the existence of the kernel of u. For every noetherian open V of X, one knows that the restriction of u to V,

$$u_V : F_V \longrightarrow G_V,$$

has a kernel in the category $\ell\text{-}\operatorname{adc}(V)$, admitting the following simple description. If K is the kernel of u_V in the category $\operatorname{Hom}(\mathbb{N}^\circ, \operatorname{Ab}(V))$, K satisfies the Mittag-Leffler-Artin-Rees condition and, denoting by K' its projective system of universal images, there exists an integer r such that the projective system

$$m_r(K') = \left(K'_{n+r}/\ell^{n+1}K'_{n+r}\right)_{n\in\mathbb{N}}$$

(with the evident transition morphisms) is constructible ℓ-adic. The evident composite below is a kernel of u_V in the category $\ell\text{-}\operatorname{adc}(V)$:

$$m_r(K') \longrightarrow K' \longrightarrow K.$$

The preceding construction shows in particular that, if W is an open contained in V, the restriction to W of a kernel for u_V is a kernel for u_W. Let $(V_i)_{i\in I}$ be a covering of X by noetherian opens. If i and j are two elements of I, the restrictions to $V_i \cap V_j$ of the kernels of u_{V_i} and u_{V_j} are canonically isomorphic, which allows them to be glued to construct a kernel of u.

1.1.4

Let $F = (F_n)_{n\in\mathbb{N}}$ be a constructible ℓ-adic sheaf. Since the ring $\mathbb{Z}_\ell$ acts evidently on each sheaf F_n, it also acts on F. Moreover, if F and G are two constructible ℓ-adic sheaves and

$$u : F \longrightarrow G$$

is a morphism, u is compatible with the actions of $\mathbb{Z}_\ell$ on F and G, respectively. This shows that $\ell\text{-}\operatorname{adc}(X)$ is canonically endowed with the structure of an abelian $\mathbb{Z}_\ell$-category.

This justifies the following terminology.

Terminology. In what follows, constructible ℓ-adic sheaves will be called constructible $\mathbb{Z}_\ell$-sheaves.

One should take care not to confuse this notion with that of a $(\mathbb{Z}_\ell)_X$-module, which will not be used below.

The category $\ell\text{-}\operatorname{adc}(X)$ will also be denoted

$$\mathbb{Z}_\ell\text{-}\operatorname{fc}(X).$$

1.2. Constructible twisted constant $\mathbb{Z}_\ell$-sheaves

Definition 1.2.1. A constructible $\mathbb{Z}_\ell$-sheaf

$$F = (F_n)_{n\in\mathbb{N}}$$

is said to be twisted constant if and only if the sheaves F_n are locally constant on $X_{\text{ét}}$.

The category of constructible twisted constant $\mathbb{Z}_\ell$-sheaves is the full subcategory of $\mathbb{Z}_\ell$- $\mathrm{fc}(X)$ generated by the constructible twisted constant $\mathbb{Z}_\ell$-sheaves.

Example 1.2.2. The $\mathbb{Z}_\ell$-sheaf $\mathbb{Z}_\ell(1)$.

Assume that the integer ℓ is prime to the residual characteristics of X. For every integer n, raising to the ℓ-th power defines a morphism of locally constant sheaves:

$$\mu_{\ell^{n+1}} \longrightarrow \mu_{\ell^n}.$$

This evidently defines a projective system:

$$\mathbb{Z}_\ell(1) = (\mu_{\ell^{n+1}})_{n\in\mathbb{N}}.$$

Reducing, for each integer n, to the case where μ_{ℓ^n} and $\mu_{\ell^{n+1}}$ are constant, one sees that the projective system $\mathbb{Z}_\ell(1)$ is ℓ-adic.

When $X = \mathrm{Spec}(K)$, where K is a field of finite type over the prime field, the $\mathbb{Z}_\ell$-sheaf $\mathbb{Z}_\ell(1)$ is an example of a constructible twisted constant ℓ-adic sheaf (1.2.1) for which there is no finite étale extension K' of K such that the inverse images of the F_n on $X' = \mathrm{Spec}(K')$ are constant. Indeed, K' would contain, for every integer n, a primitive ℓ^n-th root of unity, which is not possible for a finite-type extension of the prime field.

Reminders 1.2.3. (SGA 1 V 7). One knows that the category of constructible locally constant abelian torsion sheaves on a prescheme T is equivalent to the category of étale coverings of T endowed with the structure of an abelian X-group.

Now let X be a connected locally noetherian prescheme. Let R_X denote the category of étale coverings of X, and let Ensf denote the category of finite sets. If a is a geometric point of X, let F_a be the functor

$$F_a : R_X \longrightarrow \mathrm{Ensf},$$

which associates to every étale covering of X its geometric fibre at a. The fundamental group

$$\pi_1(X) = \pi_1(X, a)$$

of X at a, being by definition the group of automorphisms of F_a, suitably topologized, allows the functor F_a to be interpreted as a functor

$$R_X \longrightarrow \mathrm{Ensf}(\pi_1)$$

from the category R_X to the category of finite sets endowed with a continuous action of $\pi_1 = \pi_1(X, a)$.

Recall the following proposition.

Proposition 1.2.3.1. The functor

$$F_a : R_X \longrightarrow \mathrm{Ensf}(\pi_1)$$

is an equivalence of categories. It commutes with inductive limits and finite projective limits.

Let $Lc(X)$ and $\mathrm{Abf}(\pi_1)$ denote respectively the category of constructible locally constant abelian torsion sheaves and the category of finite abelian groups endowed with a continuous operation of the fundamental group. The functor F_a induces an exact functor, still denoted F_a,

$$F_a : Lc(X) \longrightarrow \mathrm{Abf}(\pi_1),$$

which is an equivalence of categories.

1.2.4. Twisted constant $\mathbb{Z}_\ell$-sheaves on a connected prescheme

The reminders in (1.2.3) make the lemma below immediate.

Lemma 1.2.4.1. The extension $\widehat{F}_a$ of F_a to the category of projective systems indexed by $\mathbb{N}$ induces an equivalence from the category of constructible twisted constant ℓ-adic sheaves to the category

$$(\ell\mathbb{Z})\text{-}\,\mathrm{ad}(\mathrm{Abf}(\pi_1)).$$

Now let $F = (F_n)_{n\in\mathbb{N}}$ be an object of the category

$$(\ell\mathbb{Z})\text{-}\,\mathrm{ad}(\mathrm{Abf}(\pi_1)).$$

Its projective limit

$$\varprojlim_{\mathbb{N}} F_n$$

is naturally endowed with a structure of $\mathbb{Z}_\ell$-module of finite type on which π_1 acts continuously for the ℓ-adic topology. Recall that if G and M denote respectively a profinite group and a $\mathbb{Z}_\ell$-module of finite type, a continuous operation of G on M means a continuous map

$$G \times M \longrightarrow M, \qquad (g, m) \longmapsto g \cdot m,$$

such that

$$\text{(i)} \quad g \cdot (m + n) = g \cdot m + g \cdot n \quad (g \in G,\ m, n \in M),$$

and

$$\text{(ii)} \quad (gh) \cdot m = g \cdot (h \cdot m) \quad (g, h \in G,\ m \in M).$$

It is then clear that, for every ℓ-adic integer a,

$$g \cdot (am) = a(g \cdot m) \qquad (g \in G,\ m \in M).$$

Moreover, the group of invertible $\mathbb{Z}_\ell$-linear maps from M to M, denoted $\mathrm{GL}(M)$, is identified with the projective limit of the groups $\mathrm{GL}(M/\ell^{n+1}M)$. Since these groups are finite, the group $\mathrm{GL}(M)$ is thus naturally endowed with the structure of a profinite group, and in particular with the structure

of a compact topological group. One checks easily that to give a continuous operation of the profinite group G on M is the same as to give a morphism of topological groups

$$G \longrightarrow \mathrm{GL}(M),$$

where the latter group is endowed with the topology just described. This said, one evidently defines a functor

$$\varprojlim_{\mathbb{N}} : (\ell\mathbb{Z})\text{-}\,\mathrm{ad}(\mathrm{Abf}(\pi_1)) \longrightarrow \mathbb{Z}_\ell\text{-}\,\mathrm{mod}(\pi_1),$$

where $\mathbb{Z}_\ell\text{-}\,\mathrm{mod}(\pi_1)$ denotes the category of finite-type $\mathbb{Z}_\ell$-modules endowed with a continuous operation of π_1.

This allows us to state the following lemma.

Lemma 1.2.4.2. The preceding functor

$$\varprojlim_{\mathbb{N}} : (\ell\mathbb{Z})\text{-}\,\mathrm{ad}(\mathrm{Abf}(\pi_1)) \longrightarrow \mathbb{Z}_\ell\text{-}\,\mathrm{mod}(\pi_1)$$

is an equivalence of categories.

Proof. It is clear that it is essentially surjective: a finite-type $\mathbb{Z}_\ell$-module E on which π_1 acts continuously is the image of the projective system

$$(E/\ell^{n+1}E)_{n\in\mathbb{N}},$$

with the evident operations of π_1. Now let

$$F = (F_n)_{n\in\mathbb{N}}, \qquad G = (G_n)_{n\in\mathbb{N}}$$

be two objects of the category $(\ell\mathbb{Z})\text{-}\,\mathrm{ad}(\mathrm{Abf}(\pi_1))$, and, for simplicity, write $\mathrm{Hom}_{\pi_1}(F,G)$ for the set of morphisms from F to G in this category. Forgetting the action of π_1, one may regard F and G as objects of the category of ℓ-adic projective systems of finite abelian groups, and write $\mathrm{Hom}_0(F,G)$ for the set of morphisms from F to G in this category. The group π_1 acts on $\mathrm{Hom}_0(F,G)$ as follows: an element s of π_1 clearly defines two automorphisms, denoted in the same way, of F and G respectively in the category of ℓ-adic projective systems of finite abelian groups, and if u belongs to $\mathrm{Hom}_0(F,G)$, one puts

$$s \cdot u = sus^{-1}.$$

Under these conditions, it is clear that $\mathrm{Hom}_{\pi_1}(F,G)$ is canonically identified with the set of π_1-invariants in $\mathrm{Hom}_0(F,G)$, and similarly that $\mathrm{Hom}_{\pi_1}(F_n,G_n)$ is identified for every n with

$$\mathrm{Hom}_{\mathbb{Z}}(F_n,G_n)^{\pi_1},$$

the operation of π_1 being defined analogously. It follows, for example, from (Serre, Groupes proalgébriques, Prop. 12) that, denoting by M and N the projective limits of F and G respectively, one has

$$\mathrm{Hom}_{\mathbb{Z}_\ell}(M,N) = \varprojlim_{n} \mathrm{Hom}_{\mathbb{Z}}(F_n,G_n).$$

Taking the invariants of both sides under π_1 and using the fact that this operation, being associated with a projective limit, commutes with projective limits, one obtains the assertion.

Lemmas 1.2.4.1 and 1.2.4.2 allow one to state the following less precise proposition.

Proposition 1.2.5. The category of constructible twisted constant $\mathbb{Z}_\ell$-sheaves on a connected locally noetherian prescheme X is equivalent to the category of finite-type $\mathbb{Z}_\ell$-modules on which $\pi_1(X)$ acts continuously for the ℓ-adic topology.

Remark. Let F be a constructible twisted constant $\mathbb{Z}_\ell$-sheaf, and let M be the corresponding finite-type $\mathbb{Z}_\ell$-module endowed with a continuous operation of π_1. For F to be locally constant, it is clear that it is enough for π_1 to act on M through a finite quotient; this is not always the case (1.2.2). It is even necessary when X is normal. After decomposing X into connected components, one may, in order to see this, reduce to the case where X is integral. I claim that then, if K denotes its field of rational functions, and if there exists a finite separable extension K' of K such that the inverse image $F_{K'}$ of F above $\mathrm{Spec}(K')$ is constant, then the group $\pi_1(X)$ acts on M through a finite group. Indeed (SGA 1 V 8.2), $\pi_1(K) \to \pi_1(X)$ is surjective, and the hypothesis means that the kernel of the composite

$$\pi_1(K) \longrightarrow \pi_1(X) \longrightarrow \mathrm{Aut}(M)$$

has finite index. The same is therefore true for the kernel of $\pi_1(X) \to \mathrm{Aut}(M)$.

Proposition 1.2.6. Let X be a locally noetherian prescheme and let F be a projective system, indexed by $\mathbb{N}$, of abelian sheaves on $X_{\text{ét}}$. The following assertions are equivalent:

(i) F is a constructible $\mathbb{Z}_\ell$-sheaf;

(ii) every noetherian open U of X is a finite union of locally closed subsets $(Z_i)_{1\leq i\leq q}$ above which the inverse image of F is a constructible twisted constant $\mathbb{Z}_\ell$-sheaf;

(iii) X admits a covering by opens, each a finite union of locally closed subsets, above which the inverse image of F is a constructible twisted constant $\mathbb{Z}_\ell$-sheaf.

Proof. It is clear that (ii) implies (iii).

(iii) $\Longrightarrow$ (i): If F satisfies (iii), its geometric fibres are ℓ-adic, hence F is ℓ-adic by (SGA 4 VIII 3.6). Moreover, its components are constructible (SGA 4 IX 2.8).

To see that (i) implies (ii), one immediately reduces to the case where X is noetherian. If F is constructible ℓ-adic, its strict graded object $\mathrm{gr}^s(F)$ is a noetherian $(\mathrm{gr}_\ell\,\mathbb{Z}, \mathrm{Ab}(X))$-module (V 5.1.6). It follows (SGA 4 IX 2.9) that X is a finite union of locally closed subsets $(Z_i)_{1\leq i\leq q}$ above which the inverse image of $\mathrm{gr}^s(F)$ is a locally constant sheaf. Since, for a sheaf with finite fibres, the property of being locally constant is stable under extensions, one deduces that, for every integer n, the inverse images on each Z_i of the component F_n of F are locally constant sheaves.

1.3. Operations $\otimes$ and Hom on $\mathbb{Z}_\ell$-sheaves

1.3.1. Tensor product. Let F and G be two objects of the category $\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X))$. If

$$F = (F_n)_{n\in\mathbb{N}} \quad \text{and} \quad G = (G_n)_{n\in\mathbb{N}},$$

the tensor product $F \otimes G$ of F and G is defined by the following formula on objects, and in the evident way on arrows:

$$(F \otimes G)_n = F_n \otimes G_n.$$

More precisely one clearly defines a right exact additive bifunctor, called the tensor product:

$$\otimes : \mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X)) \times \mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X)) \longrightarrow \mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X)).$$

Proposition 1.3.2. If F and G are two constructible $\mathbb{Z}_\ell$-sheaves, then the tensor product $F \otimes G$ is a constructible $\mathbb{Z}_\ell$-sheaf.

Proof. The ℓ-adic property is clear. Moreover, it follows immediately from the definition of constructible sheaves (SGA 4 IX 2.3) that a tensor product of two constructible sheaves is constructible.

By restriction one therefore defines a right exact additive bifunctor, again called tensor product:

$$\otimes : \mathbb{Z}_\ell\text{-}\,\mathrm{fc}(X) \times \mathbb{Z}_\ell\text{-}\,\mathrm{fc}(X) \longrightarrow \mathbb{Z}_\ell\text{-}\,\mathrm{fc}(X).$$

1.3.3. Sheaf of homomorphisms

Let $F = (F_n)_{n\in\mathbb{N}}$ and $G = (G_n)_{n\in\mathbb{N}}$ be two constructible $\mathbb{Z}_\ell$-sheaves. Suppose that F is locally free, meaning that, for every integer n, the sheaf F_n is locally free over the constant sheaf

$$(\mathbb{Z}/\ell^{n+1}\mathbb{Z})_X.$$

For every integer n, the structural exact sequence

$$G_{n+1} \xrightarrow{\ell^{n+1}} G_{n+1} \longrightarrow G_n \longrightarrow 0$$

gives, since F_{n+1} is locally free over $(\mathbb{Z}/\ell^{n+1}\mathbb{Z})_X$, an exact sequence

$$\mathcal{H}om(F_{n+1}, G_{n+1}) \xrightarrow{\ell^{n+1}} \mathcal{H}om(F_{n+1}, G_{n+1}) \longrightarrow \mathcal{H}om(F_{n+1}, G_n) \longrightarrow 0. \tag{1}$$

Since $\ell^{n+1}G_n = 0$, the structural exact sequence

$$F_{n+1} \xrightarrow{\ell^{n+1}} F_{n+1} \longrightarrow F_n \longrightarrow 0$$

clearly defines an isomorphism

$$\mathcal{H}om(F_{n+1}, G_n) \xleftarrow{\sim} \mathcal{H}om(F_n, G_n). \tag{2}$$

Combining (1) and (2), one obtains, for every integer n, a morphism

$$\mathcal{H}om(F_{n+1}, G_{n+1}) \longrightarrow \mathcal{H}om(F_n, G_n).$$

Hence a projective system

$$\mathcal{H}om(F, G) = \big(\mathcal{H}om(F_n, G_n)\big)_{n\in\mathbb{N}},$$

which is clearly a $\mathbb{Z}_\ell$-sheaf.

1.3.4. Generalities on invertible ℓ-adic sheaves. Application to the sheaves $\mathbb{Z}_\ell(r)$ ($r \in \mathbb{Z}$)

Let L be a constructible $\mathbb{Z}_\ell$-sheaf. We shall say that it is invertible if, for every integer n, its n-th component L_n is an invertible $(\mathbb{Z}/\ell^{n+1}\mathbb{Z})_X$-module, i.e. locally free of rank one. This is equivalent to saying that L is locally free in the sense of the preceding paragraph and that the geometric fibres of the L_n are nonzero cyclic abelian groups.

If L is an invertible $\mathbb{Z}_\ell$-sheaf, we agree to put

$$L^{-1} = \mathcal{H}om(L, \mathbb{Z}_\ell).$$

It is clear that there is an isomorphism

$$L \otimes L^{-1} \xrightarrow{\sim} \mathbb{Z}_\ell,$$

deduced componentwise from the analogous isomorphism (EGA 0_I 5.4.3.1). Following (EGA 0_I 5.4.4), we agree to put $L^{\otimes 0} = \mathbb{Z}_\ell$ and, for $n \geq 1$,

$$L^{\otimes -n} = (L^{-1})^{\otimes n}.$$

With this notation, there is then a canonical functorial isomorphism

$$L^{\otimes m} \otimes L^{\otimes n} \xrightarrow{\sim} L^{\otimes (m+n)}$$

for all rational integers m and n. Moreover, this isomorphism has the usual associativity properties.

In particular, the graded objects

$$(L^{\otimes i})_{i \in \mathbb{N}} \quad \text{and} \quad (L^{\otimes i})_{i \in \mathbb{Z}}$$

are $\mathbb{Z}_\ell$-algebras, graded respectively by $\mathbb{N}$ and $\mathbb{Z}$.

Example. The $\mathbb{Z}_\ell$-sheaf $\mathbb{Z}_\ell(1)$ defined in (1.2.2) is invertible, and in what follows we shall agree to put

$$\mathbb{Z}_\ell(r) = \big(\mathbb{Z}_\ell(1)\big)^{\otimes r} \qquad (r \in \mathbb{Z}).$$

1.4. Various categories constructed from the category of constructible $\mathbb{Z}_\ell$-sheaves

1.4.1. Constructible A-sheaves (A a finite $\mathbb{Z}_\ell$-algebra). Let A be a finite $\mathbb{Z}_\ell$-algebra. Define a category denoted

$$A\text{-}\operatorname{fc}(X),$$

whose objects are called constructible A-sheaves, as follows.

(i) An object of $A\text{-}\operatorname{fc}(X)$ is a pair (F, u) consisting of a constructible $\mathbb{Z}_\ell$-sheaf F and a morphism of $\mathbb{Z}_\ell$-algebras

$$u : A \longrightarrow \operatorname{End}(F).$$

(ii) If (F, u) and (F', u') are two constructible A-sheaves, an arrow $(F, u) \to (F', u')$ is a morphism of $\mathbb{Z}_\ell$-sheaves

$$f : F \longrightarrow F'$$

such that, for every element a of A, the diagram below is commutative:

$$\begin{array}{ccc} F & \xrightarrow{f} & F' \\ {\scriptstyle u(a)}\downarrow & & \downarrow{\scriptstyle u'(a)} \\ F & \xrightarrow[f]{} & F'. \end{array}$$

A constructible twisted constant A-sheaf is a constructible A-sheaf whose underlying constructible $\mathbb{Z}_\ell$-sheaf is twisted constant. The category of constructible twisted constant A-sheaves is the full subcategory of the category of constructible A-sheaves generated by the constructible twisted constant A-sheaves.

It follows immediately from (1.2.4) that, if X is connected, the category of constructible twisted constant A-sheaves is equivalent to the category of finite-type A-modules endowed with a continuous A-linear operation of $\pi_1(X)$ on the underlying finite-type $\mathbb{Z}_\ell$-module (1.2.4).

1.4.2. Constructible $\mathbb{Q}_\ell$-sheaves. It is clear that the full subcategory of $\mathbb{Z}_\ell$- fc(X) generated by the constructible $\mathbb{Z}_\ell$-sheaves of torsion, i.e. killed by a power of ℓ, is thick.

Definition 1.4.3. The category of constructible $\mathbb{Q}_\ell$-sheaves on X, denoted

$$\mathbb{Q}_\ell\text{- fc}(X),$$

is the quotient abelian category, in the sense of Gabriel's thesis, of $\mathbb{Z}_\ell$- fc(X) by the thick abelian subcategory of $\mathbb{Z}_\ell$-sheaves of torsion. An object of $\mathbb{Q}_\ell$- fc(X) is called a constructible $\mathbb{Q}_\ell$-sheaf.

The category $\mathbb{Q}_\ell$- fc(X) admits the following simple description. It has the same set of objects as $\mathbb{Z}_\ell$- fc(X), and, if F and G are two such objects,

$$\mathrm{Hom}_{\mathbb{Q}_\ell}(F, G) = \mathbb{Q}_\ell \otimes_{\mathbb{Z}_\ell} \mathrm{Hom}_{\mathbb{Z}_\ell}(F, G),$$

where $\mathrm{Hom}_{\mathbb{Z}_\ell}(F, G)$ and $\mathrm{Hom}_{\mathbb{Q}_\ell}(F, G)$ denote respectively the morphisms in $\mathbb{Z}_\ell$- fc(X) and $\mathbb{Q}_\ell$- fc(X). Indeed, if

$$u : \mathbb{Z}_\ell\text{- fc}(X) \longrightarrow D$$

denotes an exact functor from $\mathbb{Z}_\ell$- fc(X) to an abelian category D, then to say that u makes multiplication by the elements of $\mathbb{Z}_\ell$ invertible is the same as to say that u vanishes on the torsion objects; this immediately shows that the abelian category described above by objects and morphisms solves the universal problem of passage to the quotient.

A constructible $\mathbb{Q}_\ell$-sheaf is said to be twisted constant if it is the image of a constructible twisted constant $\mathbb{Z}_\ell$-sheaf. The category of constructible twisted constant $\mathbb{Q}_\ell$-sheaves is the full subcategory of

$$\mathbb{Q}_\ell\text{- fc}(X)$$

generated by the constructible twisted constant $\mathbb{Q}_\ell$-sheaves.

It follows from (1.2.4) that, if X is connected, the category of constructible twisted constant $\mathbb{Q}_\ell$-sheaves is equivalent to the category of finite-dimensional $\mathbb{Q}_\ell$-vector spaces V endowed with a continuous operation of $\pi_1(X)$, i.e. a continuous map

$$u : \pi_1(X) \times V \longrightarrow V$$

satisfying the properties made explicit in (1.2.4), which in particular implies that $u(g, v)$ is $\mathbb{Q}_\ell$-linear in v for every $g \in \pi_1(X)$.

It is immediate to see that this is equivalent to giving a morphism of topological groups

$$\pi_1(X) \longrightarrow \mathrm{GL}(V),$$

the latter being endowed with its natural topology as an ℓ-adic analytic group.

1.4.3. Constructible L-sheaves (L a finite $\mathbb{Q}_\ell$-algebra). Let L be a finite $\mathbb{Q}_\ell$-algebra. In a manner analogous to what was done in (1.4.1) starting from constructible $\mathbb{Z}_\ell$-sheaves, one defines, starting from the category of constructible $\mathbb{Q}_\ell$-sheaves, the category of constructible L-sheaves, and then the category of constructible twisted constant L-sheaves. If X is connected, the category of constructible twisted constant L-sheaves is equivalent to the category of finite-dimensional L-vector spaces endowed with a continuous operation of $\pi_1(X)$, i.e. a continuous operation of $\pi_1(X)$ on the underlying $\mathbb{Q}_\ell$-vector space, commuting with the operation of L.

1.4.4

If A is a finite commutative $\mathbb{Z}_\ell$-algebra and F, G are two constructible A-sheaves, the projective system

$$F \otimes_A G = (F_n \otimes_{A_X} G_n)_{n\in\mathbb{N}},$$

with the evident transition morphisms, is a $\mathbb{Z}_\ell$-sheaf. Moreover A acts evidently on each of its components, which allows it to be endowed naturally with the structure of an A-sheaf. Thus one defines a right exact bifunctor, called tensor product,

$$A\text{-}\,\mathrm{fc}(X) \times A\text{-}\,\mathrm{fc}(X) \longrightarrow A\text{-}\,\mathrm{fc}(X).$$

Now let F and G be two A-sheaves and suppose that F is locally free, i.e. that, for every integer n, F_n is a locally free $(A/\ell^{n+1}A)_X$-module. Then, as in (1.3.2), one sees that the projective system

$$\mathcal{H}om_A(F, G) = \left(\mathcal{H}om_{A_n}(F_n, G_n)\right)_{n\in\mathbb{N}},$$

with the evident transition morphisms, is a $\mathbb{Z}_\ell$-sheaf. Moreover, since A acts naturally on its components, it is canonically endowed with the structure of an A-sheaf.

As in (1.3.3), one defines the notion of an invertible A-sheaf and, if L is such an A-sheaf, gives a meaning to the expression $L^{\otimes r}$ for every natural integer r. Paragraph (1.3.3) adapts without difficulty to this situation.

1.4.5

Let F be a constructible $\mathbb{Z}_\ell$-sheaf, and let p be the canonical functor

$$\mathbb{Z}_\ell\text{-}\operatorname{fc}(X) \longrightarrow \mathbb{Q}_\ell\text{-}\operatorname{fc}(X).$$

The composite of p with the functor $G \mapsto F \otimes G$ makes multiplication by the elements of $\mathbb{Z}_\ell$ invertible and hence defines a functor

$$\mathbb{Q}_\ell\text{-}\operatorname{fc}(X) \longrightarrow \mathbb{Q}_\ell\text{-}\operatorname{fc}(X),$$

which is right exact. Applying the same argument to the first variable, one thus defines a right exact bifunctor, called tensor product,

$$\mathbb{Q}_\ell\text{-}\operatorname{fc}(X) \times \mathbb{Q}_\ell\text{-}\operatorname{fc}(X) \longrightarrow \mathbb{Q}_\ell\text{-}\operatorname{fc}(X).$$

If X is connected and F and G are two constructible twisted constant $\mathbb{Q}_\ell$-sheaves corresponding to representations of $\pi_1(X)$ on vector spaces V and W, respectively, then the tensor product $F \otimes G$ is again locally constant and corresponds to the diagonal representation of $\pi_1(X)$ on $V \otimes W$.

1.4.6

Let F be a locally free constructible $\mathbb{Z}_\ell$-sheaf (1.3.3). The composite of p with the functor $G \mapsto \mathcal{H}om(F, G)$ (1.3.2) makes multiplication by elements of $\mathbb{Z}_\ell$ invertible and hence defines a functor

$$\mathcal{H}om(F, \cdot) : \mathbb{Q}_\ell\text{-}\operatorname{fc}(X) \longrightarrow \mathbb{Q}_\ell\text{-}\operatorname{fc}(X).$$

If F and F' are two locally free constructible $\mathbb{Z}_\ell$-sheaves defining isomorphic $\mathbb{Q}_\ell$-sheaves, then there exists a morphism of $\mathbb{Z}_\ell$-sheaves

$$u : F \longrightarrow F'$$

whose kernel and cokernel are torsion. This immediately shows that the functors $\mathcal{H}om(F, \cdot)$ and $\mathcal{H}om(F', \cdot)$ from $\mathbb{Q}_\ell\text{-}\operatorname{fc}(X)$ to itself are isomorphic.

Now let F be a constructible twisted constant $\mathbb{Q}_\ell$-sheaf. If we again denote by F the corresponding $\mathbb{Z}_\ell$-sheaf, it follows from the interpretation of the restrictions of F to the connected components Y of X as continuous $\pi_1(Y)$-modules that F may be written uniquely, up to isomorphism, in the form

$$F = P \oplus T,$$

where P is locally free and T is torsion. This allows one to define, for every $\mathbb{Q}_\ell$-sheaf G, a $\mathbb{Q}_\ell$-sheaf

$$\mathcal{H}om(F, G) = \mathcal{H}om(P, G).$$

An isomorphism $u : F \to F'$ of $\mathbb{Q}_\ell$-sheaves defines, for every G, an isomorphism

$$\mathcal{H}om(F', G) \xrightarrow{\sim} \mathcal{H}om(F, G).$$

More precisely, one thereby defines a bifunctor

$$\mathcal{H}om : (\mathbb{Q}_\ell\text{-}\operatorname{fct}(X))^\circ \times \mathbb{Q}_\ell\text{-}\operatorname{fc}(X) \longrightarrow \mathbb{Q}_\ell\text{-}\operatorname{fc}(X),$$

where $\mathbb{Q}_\ell\text{-}\operatorname{fct}(X)$ denotes the category of constructible twisted constant $\mathbb{Q}_\ell$-sheaves. This bifunctor has the usual exactness properties.

1.4.7

Let L now be a finite-type extension of $\mathbb{Q}_\ell$, and let A denote the integral closure of $\mathbb{Z}_\ell$ in L, so that A is a free $\mathbb{Z}_\ell$-algebra of finite type and a Dedekind ring. The category of constructible L-sheaves is isomorphic to the quotient category of the category of constructible A-sheaves by the category of constructible torsion A-sheaves. This allows one, as in (1.4.6), to define from the tensor product of (1.4.4) a tensor product:

$$L\text{-}\operatorname{fc}(X) \times L\text{-}\operatorname{fc}(X) \longrightarrow L\text{-}\operatorname{fc}(X).$$

Since A is a Dedekind ring, the argument used in (1.4.6) shows that every twisted constant A-sheaf is the direct sum of a locally free A-sheaf and a torsion A-sheaf. Denoting by $L\text{-}\operatorname{fct}(X)$ the category of constructible twisted constant L-sheaves, one defines, again as in (1.4.6), a bifunctor

$$\mathcal{H}om : (L\text{-}\operatorname{fct}(X))^\circ \times L\text{-}\operatorname{fc}(X) \longrightarrow L\text{-}\operatorname{fc}(X),$$

with the usual exactness properties.

1.5. Constructible $(AR, \mathbb{Z}_\ell)$-sheaves

Definition 1.5.1. Let X be a locally noetherian prescheme. An object F of $\operatorname{Hom}(\mathbb{N}^\circ, \operatorname{Ab}(X))$ is called a constructible $(AR, \mathbb{Z}_\ell)$-sheaf if X admits a covering

$$(U_i)_{i\in I}$$

by noetherian opens such that the restriction of F above each U_i is a $(AR, \ell\mathbb{Z})$-noetherian object (V 1.3).

It follows immediately from (V 5.2.1) that the full subcategory of $\operatorname{Hom}(\mathbb{N}^\circ, \operatorname{Ab}(X))$ generated by the constructible $(AR, \mathbb{Z}_\ell)$-sheaves is stable under kernels and cokernels. In particular, it is an abelian category.

1.5.2. Constructible $(AR, \mathbb{Z}_\ell)$-sheaves which are locally AR-null

It is clear that an AR-null object (V 2.2.1) of $\operatorname{Hom}(\mathbb{N}^\circ, \operatorname{Ab}(X))$ is a constructible $(AR, \mathbb{Z}_\ell)$-sheaf if and only if its components are constructible. It follows in particular from (V 2.2.2) and (SGA 4 IX 2.6) that the category of AR-null constructible $(AR, \mathbb{Z}_\ell)$-sheaves is a thick abelian subcategory of the full category generated by the constructible $(AR, \mathbb{Z}_\ell)$-sheaves in $\operatorname{Hom}(\mathbb{N}^\circ, \operatorname{Ab}(X))$.

Agreeing to say that an object P of $\operatorname{Hom}(\mathbb{N}^\circ, \operatorname{Ab}(X))$ is locally AR-null if there exists an open covering of X for the étale topology (or, equivalently, for the Zariski topology) above each open of which P is AR-null, one sees, by reducing through localization to the preceding case, that the category of locally AR-null constructible $(AR, \mathbb{Z}_\ell)$-sheaves is a thick abelian subcategory of that of constructible $(AR, \mathbb{Z}_\ell)$-sheaves.

Observe that, if X is noetherian, the constructible $(AR, \mathbb{Z}_\ell)$-sheaves are the noetherian $(AR, \ell\mathbb{Z})$-adic objects of $\operatorname{Hom}(\mathbb{N}^\circ, \operatorname{Ab}(X))$, and locally AR-null is equivalent to AR-null.

Definition 1.5.3. Let X be a locally noetherian prescheme. The category of constructible $(AR, \mathbb{Z}_\ell)$-sheaves on X, denoted

$$(AR, \mathbb{Z}_\ell)\text{-}\operatorname{fc}(X),$$

is the quotient abelian category of the full subcategory generated by the constructible $(AR, \mathbb{Z}_\ell)$-sheaves in

$$\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X))$$

by the full thick subcategory generated by the locally AR-null constructible $(AR, \mathbb{Z}_\ell)$-sheaves.

Notation 1.5.4. Whenever useful, $U(X)$ will denote the full subcategory of $\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X))$ generated by the constructible $(AR, \mathbb{Z}_\ell)$-sheaves.

Since every constructible $\mathbb{Z}_\ell$-sheaf is in particular a constructible $(AR, \mathbb{Z}_\ell)$-sheaf, one defines in the evident way a functor

$$u : \mathbb{Z}_\ell\text{-}\,\mathrm{fc}(X) \longrightarrow (AR, \mathbb{Z}_\ell)\text{-}\,\mathrm{fc}(X).$$

Proposition 1.5.5. The above functor u is an equivalence of categories.

Proof. To prove that u is fully faithful and essentially surjective, one reduces "by gluing" as in the proof of 1.1.3 to the analogous statement (V 5.1.3).

2. Formalism of ℓ-adic cohomology

2.1. Inverse image

Let

$$f : X \longrightarrow Y$$

be a morphism of locally noetherian preschemes. The inverse-image functor

$$f^* : \mathrm{Ab}(Y) \longrightarrow \mathrm{Ab}(X)$$

is exact and therefore extends in the evident way to an exact functor, denoted in the same way,

$$f^* : \mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(Y)) \longrightarrow \mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X)).$$

This latter functor evidently carries constructible $\mathbb{Z}_\ell$-sheaves to constructible $\mathbb{Z}_\ell$-sheaves, and locally AR-null projective systems to locally AR-null projective systems. With the notation of (1.5.4), it therefore induces two "inverse image" functors

$$f^* : \mathbb{Z}_\ell\text{-}\,\mathrm{fc}(Y) \longrightarrow \mathbb{Z}_\ell\text{-}\,\mathrm{fc}(X),$$

$$f^* : U(Y) \longrightarrow U(X),$$

the second of which is exact.

The equivalence of categories (1.5.5), together with the fact that f^* carries locally AR-null projective systems to locally AR-null projective systems, then shows that the inverse-image functor

$$f^* : \mathbb{Z}_\ell\text{-}\,\mathrm{fc}(Y) \longrightarrow \mathbb{Z}_\ell\text{-}\,\mathrm{fc}(X)$$

is also exact.

If $g : Y \to Z$ is another morphism of locally noetherian preschemes, the functors f^* and g^* are evidently related by an isomorphism

$$(g \circ f)^* \xrightarrow{\sim} f^* \circ g^*,$$

with the usual associativity property (SGA 1 VI 7 ff.).

2.2. Higher direct images

Let

$$f : X \longrightarrow Y$$

be a separated morphism of finite type between locally noetherian preschemes. Recall the following result of étale cohomology (SGA 4 XVII; for the proper case, cf. SGA 4 XIV 1.1).

Lemma 2.2.1. Let A be a commutative ring annihilated by a nonzero integer n, and let M be a constructible $(A, \mathrm{Ab}(X))$-module. For every integer i, the sheaf

$$R^i_! f(M)$$

is a constructible $(A, \mathrm{Ab}(Y))$-module.

The following lemma follows from this by applying (V 5.3.1) after restriction over the noetherian opens of Y.

Lemma 2.2.2. For every integer i and every constructible $(AR, \mathbb{Z}_\ell)$-sheaf F on X, the projective system

$$R^i_! f(F)$$

is a constructible $(AR, \mathbb{Z}_\ell)$-sheaf.

This said, the exact δ-functor

$$(R^i_! f)_{i\in\mathbb{Z}} : \mathrm{Ab}(X) \longrightarrow \mathrm{Ab}(Y)$$

extends in the evident way to an exact δ-functor, denoted in the same way,

$$\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X)) \longrightarrow \mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(Y)),$$

which by restriction gives an exact δ-functor

$$U(X) \longrightarrow U(Y). \tag{1}$$

Moreover, the functors $R^i_! f$ carry locally AR-null projective systems to locally AR-null projective systems; hence, after passage to the quotient, the δ-functor (1) gives an exact δ-functor

$$(R^i_! f)_{i\in\mathbb{Z}} : (AR, \mathbb{Z}_\ell)\text{- fc}(X) \longrightarrow (AR, \mathbb{Z}_\ell)\text{- fc}(Y).$$

Using now the equivalence of categories (1.5.5), this latter δ-functor is interpreted as an exact δ-functor

$$\mathbb{Z}_\ell\text{- fc}(X) \longrightarrow \mathbb{Z}_\ell\text{- fc}(Y).$$

Definition 2.2.3. The functor

$$R^i_! f : \mathbb{Z}_\ell\text{- fc}(X) \longrightarrow \mathbb{Z}_\ell\text{- fc}(Y)$$

is called the i-th direct image functor with proper supports of f.

Remark. Assuming the analogue of Lemma (2.2.1) proved for the ordinary higher direct images when X and Y are excellent, which is done in characteristic zero (SGA 4 XIX 5.1), one defines in

the same way higher direct images in ℓ-adic cohomology in that case. One could also develop the result of the following paragraph in this framework.

Proposition 2.2.4 (Leray spectral sequence). Let $f : X \to Y$ and $g : Y \to Z$ be two separated morphisms of finite type between locally noetherian preschemes, and let F be a constructible $\mathbb{Z}_\ell$-sheaf, respectively a constructible $(AR, \mathbb{Z}_\ell)$-sheaf. There exists in $\mathbb{Z}_\ell$- fc(Z) a biregular spectral sequence (EGA 0_{III} 11.1.3), functorial in F:

$$R^i_!g(R^j_!f(F)) \Longrightarrow R^{i+j}_!(g \circ f)(F).$$

Proof. By the equivalence of categories (1.5.5) and the way in which higher direct images are defined for constructible $\mathbb{Z}_\ell$-sheaves, it is enough to show the analogous statement for constructible $(AR, \mathbb{Z}_\ell)$-sheaves. For any abelian category C, let us agree to denote by $\mathrm{Sp}(C)$ the category of spectral sequences beginning at degree 2 with values in C. Associating to every object F of $\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X))$ the ordinary Leray spectral sequence, obtained by extension to projective systems,

$$R^i_!g(R^j_!f(F)) \Longrightarrow R^{i+j}_!(g \circ f)(F), \tag{S}$$

it is clear that one obtains a functor

$$\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X)) \longrightarrow \mathrm{Sp}(\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(Z))),$$

which by restriction gives, by (2.2.1) and because $U(Z)$ is thick in $\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(Z))$, a functor

$$U(X) \longrightarrow \mathrm{Sp}(U(Z)). \tag{1}$$

Since the canonical functor

$$U(Z) \longrightarrow (AR, \mathbb{Z}_\ell)\text{- fc}(Z)$$

is exact, (1) yields an additive functor

$$E : U(X) \longrightarrow \mathrm{Sp}((AR, \mathbb{Z}_\ell)\text{- fc}(Z)). \tag{2}$$

For every object F of $\mathrm{Hom}(\mathbb{N}^\circ, \mathrm{Ab}(X))$, the associated spectral sequence (S) is biregular: this follows from the analogous assertion for the components of the projective system F and from the fact that the spectral sequence under consideration is supported in the first quadrant. This shows that, for every object of $U(X)$, the corresponding spectral sequence is biregular.

Moreover, if $u : F \to G$ is a morphism of $U(X)$ whose kernel and cokernel are locally AR-null, then, because the higher direct images carry locally AR-null projective systems to locally AR-null projective systems, $E(u)$ is an isomorphism on the terms E_2^{pq}; it is therefore an isomorphism, since the spectral sequences considered are biregular. It follows that (2) defines, by passage to the quotient, a functor

$$(AR, \mathbb{Z}_\ell)\text{- fc}(X) \longrightarrow \mathrm{Sp}((AR, \mathbb{Z}_\ell)\text{- fc}(Z)), \tag{3}$$

which associates in a precise way to every constructible $(AR, \mathbb{Z}_\ell)$-sheaf F a biregular spectral sequence

$$R^i_!g(R^j_!f(F)) \Longrightarrow R^{i+j}_!(g \circ f)(F).$$

2.2.3. Other properties

A) Cohomological dimension. Let $f : X \to Y$ be a separated morphism of finite type between locally noetherian preschemes. Suppose that the relative dimension of f is at most an integer d. Then, for every constructible $(AR, \mathbb{Z}_\ell)$-sheaf F,

$$R^i_! f(F) = 0 \qquad \text{for } i > 2d.$$

This follows from the analogous assertion for the components of F (SGA 4 X 4.1 and 5.2).

B) Proper base change. Consider a cartesian square

$$\begin{array}{ccc} X' & \xrightarrow{g'} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow[g]{} & Y. \end{array}$$

Let $f : X \to Y$ and $g : Y' \to Y$ be morphisms of locally noetherian preschemes, with f separated of finite type. Let $X' = X \times_Y Y'$, which is locally noetherian since f is of finite type, and let

$$f' : X' \to Y', \qquad g' : X' \to X$$

be the canonical morphisms. For every integer i and every constructible $\mathbb{Z}_\ell$-sheaf F, there exists an isomorphism in $\mathbb{Z}_\ell$- fc(Y'), functorial in F:

$$w_i : g^*(R^i_! f(F)) \xrightarrow{\sim} R^i_! f'(g'^* F).$$

Moreover, if

$$0 \longrightarrow F' \longrightarrow F \longrightarrow F'' \longrightarrow 0$$

is an exact sequence of $\mathbb{Z}_\ell$- fc(X) (resp. of $(AR, \mathbb{Z}_\ell)$- fc(X)), then the $(w_i)_{i\in\mathbb{N}}$ commute with boundary operators; in other words, the diagrams below are commutative:

$$\begin{array}{ccc} g^*(R^i_! f(F'')) & \xrightarrow{w_i} & R^i_! f'(g'^* F'') \\ {\scriptstyle g^*(\delta)}\downarrow & & \downarrow{\scriptstyle \delta} \\ g^*(R^{i+1}_! f(F')) & \xrightarrow[w_{i+1}]{} & R^{i+1}_! f'(g'^* F'). \end{array}$$

Proof. It is enough to prove the analogous assertion for constructible $(AR, \mathbb{Z}_\ell)$-sheaves. But it is deduced by passage to the quotient from the analogous assertion for projective systems of torsion sheaves, which is an immediate consequence of the proper base-change theorem (cf. SGA 4 XII 5.1 in the proper case and SGA 4 XVII in the general case).

C) Exact sequence relative to an open and its complement. Let $f : X \to Y$ be a compactifiable morphism of locally noetherian preschemes, let U be an open of X, and let Z be the closed complement. For every constructible $\mathbb{Z}_\ell$-sheaf F, there exists an exact sequence in $\mathbb{Z}_\ell$- fc(Y), functorial in F:

$$\cdots \longrightarrow R^i_! f_U(F/U) \longrightarrow R^i_! f(F) \longrightarrow R^i_! f_Z(F/Z) \longrightarrow R^{i+1}_! f_U(F/U) \longrightarrow \cdots .$$

Proof. Analogous to that of B).

2.2.5

The formalism developed in this paragraph for $\mathbb{Z}_\ell$-sheaves extends without difficulty to A-sheaves, where A is a finite $\mathbb{Z}_\ell$-algebra, and to L-sheaves, where L is a finite extension of $\mathbb{Q}_\ell$. For example, in the case of $\mathbb{Q}_\ell$-sheaves, the fundamental point in the proofs is that all the functors considered for $\mathbb{Z}_\ell$-sheaves carry $\mathbb{Z}_\ell$-sheaves of torsion to $\mathbb{Z}_\ell$-sheaves of torsion.

3. ℓ-adic cohomology class associated with a cycle

3.1

If X is a proper scheme, or a smooth finite-type scheme, over an algebraically closed field k, one knows that, for every constructible abelian torsion sheaf M prime to the characteristic of k, the cohomology groups

$$H^i(X, M)$$

are abelian groups of finite length. This permits (2.2.1, Remark) the definition, for every $\mathbb{Z}_\ell$-sheaf F, with ℓ prime to the characteristic of k, of a noetherian (AR, ℓ)-adic projective system of abelian groups

$$H^i(X, F)$$

with the usual properties. In particular, the method used in number 2 makes it possible to define the cup-product, the inverse-image homomorphism for a morphism of schemes over k, and the direct-image homomorphism for a proper morphism of smooth schemes over k (cf. Exposé IV for the definitions in the case of torsion sheaves).

Moreover, one knows (1.2.4) that the category of $\mathbb{Z}_\ell$-sheaves on an algebraically closed field is equivalent to the category of finite-type $\mathbb{Z}_\ell$-modules, the equivalence being supplied by the projective-limit functor. In practice it will be convenient to identify the finite-type $\mathbb{Z}_\ell$-module $H^i(X, F)$ with the corresponding $\mathbb{Z}_\ell$-sheaf.

3.2

Let ℓ be a prime number $\neq \operatorname{car} k$, and let X be a smooth scheme of finite type over k. If Z is an algebraic cycle of codimension d on X, then in Exposé IV[21] one associated to it, for every integer n, a cohomology class

$$\gamma_X^{(n)}(Z) \in H^{2d}(X, (\mu_X^{(n)})^{\otimes d}),$$

where $\mu_X^{(n)}$ denotes the locally free $(\mathbb{Z}/\ell^{n+1}\mathbb{Z})_X$-module of the ℓ^{n+1}-st roots of unity. Moreover, one saw that, if $n' \geq n$, $\gamma_X^{(n)}(Z)$ is the image of $\gamma_X^{(n')}(Z)$ in

$$H^{2d}(X, (\mu_X^{(n)})^{\otimes d})$$

by the morphism

$$H^{2d}(X, (\mu_X^{(n')})^{\otimes d}) \longrightarrow H^{2d}(X, (\mu_X^{(n)})^{\otimes d})$$

deduced from raising to the power $\ell^{n'-n}$:

$$\mu_X^{(n')} \longrightarrow \mu_X^{(n)}.$$

[21] See (SGA $4^{1/2}$ Cycle).

Thus one associates to Z an element, denoted $\gamma_X(Z)$:

$$\gamma_X(Z) \in H^{2d}(X, \mathbb{Z}_\ell(d)),$$

where $\mathbb{Z}_\ell(d)$ is defined in (1.3.4). More generally, if Z is a cycle on X, one associates to it by linearity an ℓ-adic cohomology class in

$$\bigoplus_d H^{2d}(X, \mathbb{Z}_\ell(d)),$$

which is in fact the projective limit of the cohomology classes associated with Z in

$$\bigoplus_d H^{2d}(X, (\mu_X^{(n)})^{\otimes d}).$$

3.3

By passage to the limit, it is evident that the ℓ-adic cohomology classes of the preceding paragraph satisfy the same formal properties as the cohomology classes studied in Exposé IV, namely:

(i) If $f : X \to Y$ is a proper morphism of smooth preschemes over k and Z is a cycle on X, then

$$f_*(\gamma_X(Z)) = \gamma_Y(f_*(Z)). \qquad (*)$$

(ii) If $f : X \to Y$ is a morphism of smooth preschemes over k and Z is a cycle on Y, then

$$\gamma_X(f^*Z) = f^*(\gamma_Y(Z)). \qquad (**)$$

(iii) If X is a smooth prescheme over k and Z_1 and Z_2 are two cycles on X, then

$$\gamma_X(Z_1 \cdot Z_2) = \gamma_X(Z_1) \cdot \gamma_X(Z_2), \qquad (**)$$

where the dot on the left-hand side denotes the intersection product of cycles, and the one on the right-hand side the cup-product in cohomology.

(iv) Two algebraically equivalent cycles on a smooth k-prescheme have the same ℓ-adic cohomology class.

($*$) This compatibility is not proved in (SGA $4^{1/2}$ Cycle), but is not difficult to deduce from the results of loc. cit.

($**$) In the non-excessive case, see (SGA $4^{1/2}$ Cycle 2.3.8) for a precise statement.

Exposé VII

COHOMOLOGY OF SOME CLASSICAL SCHEMES AND THE COHOMOLOGICAL THEORY OF CHERN CLASSES

by

J.-P. Jouanolou

Throughout the text, an integer $\nu > 0$ is fixed and we put

$$A = \mathbb{Z}/\nu\mathbb{Z};$$

the residual characteristics of all schemes considered are assumed to be prime to the integer ν. If X is such a scheme, μ_X denotes the sheaf of ν-th roots of unity and $A^\bullet(X)$ denotes the cohomology ring

$$\bigoplus_i H^{2i}(X, \mu_X^{\otimes i}),$$

with multiplication given by cup-product.

1. Vector bundles

Let S be a scheme and let E be a locally free $\mathcal{O}_S$-module, understood to be of finite type. Put $X = \mathrm{V}(E)$ and $U = \mathrm{V}(E)^*$, the complement of the zero section, and denote by

$$p : X \to S, \qquad q : U \to S$$

the canonical projections.

Proposition 1.1. Let L be an A-module.

(i) a) For every integer $j > 0$, one has

$$R^j p_*(p^*L) = 0.$$

b) The adjunction morphism

$$L \longrightarrow p_* p^*(L)$$

is an isomorphism.

(ii) Suppose that E has constant rank r.

a)

$$R^i_! p(p^*L) = 0 \quad \text{if } i \neq 2r.$$

b) The trace morphism (SGA 4 XVIII)

$$R^{2r}_! p(p^*L) \longrightarrow L \otimes \mu_S^{\otimes -r}$$

is an isomorphism.

Proof. Part (i) follows immediately by localization for the Zariski topology from (SGA 4 XV 2.2). Assertion (ii) is essentially contained in (SGA 4 XVIII).

Corollary 1.2. Let L be an A_S-module. For every integer i, the inverse-image morphism

$$H^i(S, L) \longrightarrow H^i(X, p^*L)$$

is an isomorphism.

Proof. By (1.1), the adjunction morphism $L \to Rp_*(p^*L)$ is an isomorphism. Since $H^*(X, p^*L) \simeq H^*(S, Rp_* p^*(L))$, the assertion follows.

Proposition 1.3. Suppose that E has constant rank r. For every A_S-module L, the following properties hold.

(i) a)
$$R^i q_*(q^*L) = 0 \quad \text{if } i \neq 0, 2r-1.$$

b) The adjunction morphism
$$L \longrightarrow q_* q^*(L)$$
is an isomorphism.

c) If Y denotes the complement of U in X, then the morphism
$$R^{2r-1} q_*(q^*L) \longrightarrow L \otimes \mu_S^{\otimes -r}$$
obtained as the composite of the boundary morphism
$$R^{2r-1} q_*(q^*L) \longrightarrow R^{2r}_Y p_*(p^*L) \tag{1}$$
and the purity isomorphism (SGA 4 XVIII)
$$R^{2r}_Y p_*(p^*L) \longrightarrow L \otimes \mu_S^{\otimes -r}$$
is an isomorphism.

(ii) a)
$$R^i_! q(q^*L) = 0 \quad \text{if } i \neq 1, 2r.$$

b) The boundary morphism
$$L \longrightarrow R^1_! q(q^*L)$$
coming from the unlimited exact sequence, where $f : Y \to S$ is the canonical projection,
$$\cdots \longrightarrow R^i_! q(q^*L) \longrightarrow R^i_! p(p^*L) \longrightarrow R^i f_*(f^*L) \longrightarrow R^{i+1}_! q(q^*L) \longrightarrow \cdots$$
is an isomorphism.

c) The trace morphism
$$R^{2r}_! q(q^*L) \longrightarrow L \otimes \mu_S^{\otimes -r}$$
is an isomorphism.

Proof. Let $\alpha : U \to X$ and $\beta : Y \to X$ be the canonical immersions. One knows (SGA 4 XVI 3.7) that, putting $F = p^*(L)$,
$$F \xrightarrow{\sim} \alpha_* \alpha^*(F) \quad \text{and} \quad (R^j \alpha_*)\alpha^*(F) = 0 \quad \text{if } j \neq 0, 2r-1.$$
Moreover, the sheaves $(R^j \alpha_*)\alpha^* F$ for $j \geq 1$ have support in Y, and hence are acyclic for the functor p_*. From these remarks one obtains assertions (i) a) and b) by using the Leray spectral sequence
$$R^i p_*(R^j \alpha_*)(q^*L) \Longrightarrow R^n q_*(q^*L).$$
Assertion (i) c) follows from (1.1 (i)) and from the unlimited exact sequence
$$\cdots \longrightarrow R^i_Y p_*(p^*L) \longrightarrow R^i p_*(p^*L) \longrightarrow R^i q_*(q^*L) \longrightarrow R^{i+1}_Y p_*(p^*L) \longrightarrow \cdots .$$
The sheaf $R^{2r}_Y p_*(p^*L)$ is associated with the presheaf
$$U \longmapsto H^{2r}_{Y \times_S U}(X \times_S U, p^*L).$$

We prove (ii). Assertion c) comes from the fact that q is smooth and has connected geometric fibres of dimension r. The exact sequence mentioned in b) is obtained by applying the functor $R_!p$ to the canonical exact sequence

$$0 \longrightarrow \alpha_!(q^*L) \longrightarrow p^*L \longrightarrow \beta_!(\beta^*p^*L) \longrightarrow 0.$$

Using (1.1 (i)), one obtains assertions (ii) a) and b) without difficulty from this unlimited exact sequence.

Remark 1.4. For $S = \mathrm{Spec}(\mathbb{C})$, (1.3) says that the complement of the origin in $\mathbb{C}^r$ has the same cohomology as the real sphere of dimension $2r-1$, a deformation retract of $\mathbb{C}^r - 0$.

Corollary 1.5 (Gysin exact sequence). The Leray spectral sequence

$$H^i(S, R^jq_*(q^*L)) \Rightarrow H^{i+j}(U, q^*L)$$

defines an unlimited exact sequence, called the Gysin exact sequence,

$$\cdots \longrightarrow H^i(S, L) \longrightarrow H^i(U, q^*L) \longrightarrow H^{i-2r+1}(S, L \otimes \mu_S^{\otimes -r}) \longrightarrow H^{i+1}(S, L) \longrightarrow \cdots .$$

Proof. Lemma of two lines.

2. Projective schemes

In what follows, the mode of exposition adopted is based on a suggestion of L. Illusie, and the method followed is close to a method of P. Deligne for proving the degeneration of certain spectral sequences [6].

2.1

Let X and Y be two schemes and let $f : X \to Y$ be a morphism. We shall define an arrow

$$Rf_*(A_X) \otimes^L Rf_*(A_X) \longrightarrow Rf_*(A_X) \tag{2.1.1}$$

in $D(Y)$, having the usual associativity and commutativity properties, and therefore endowing $Rf_*(A_X)$ with a structure of generalized algebra. For this, write

$$C^*(X, A_X)$$

for the Godement resolution of A_X (SGA 4 XVII). Proceeding as in (TF 6.6), one defines a morphism of resolutions

$$C^*(X, A_X) \otimes C^*(X, A_X) \longrightarrow C^*(X, A_X \otimes A_X).$$

Composing it with the morphism

$$C^*(X, A_X \otimes A_X) \longrightarrow C^*(X, A_X)$$

deduced from the multiplication of A_X, one finally obtains a morphism

$$C^*(X, A_X) \otimes C^*(X, A_X) \longrightarrow C^*(X, A_X). \tag{2.1.2}$$

Applying the functor f_*, one obtains without difficulty a morphism of complexes of A_Y-modules

$$f_*C^*(X, A_X) \otimes f_*C^*(X, A_X) \longrightarrow f_*C^*(X, A_X),$$

and hence (2.1.1), using flat resolutions of the components of the expression on the left.

2.2

Let S be a scheme and let E be a locally free $\mathcal{O}_S$-module of rank $r+1$. We denote by

$$P = P_S(E) \xrightarrow{p} S$$

the corresponding projective bundle. The canonical $\mathcal{O}_P$-module $\mathcal{O}_P(1)$ defines, as is known, by means of the Kummer exact sequence, an element

$$\xi \in H^2(P, \mu),$$

and we shall denote by η the image of ξ under the canonical morphism

$$H^2(P, \mu) \longrightarrow H^0(S, R^2p_*(\mu))$$

coming from the Leray spectral sequence

$$H^i(S, R^jp_*(\mu)) \Rightarrow H^{i+j}(P, \mu).$$

The class ξ is identified with an arrow $A_P \to \mu_P[2]$ in $D(P)$, which by transposition defines $\mu_P^{\otimes -1}[-2] \to A_P$, and hence by the usual adjunction an arrow

$$c : \mu_S^{\otimes -1}[-2] \longrightarrow Rp_*(A_P),$$

coinciding with η on cohomology in dimension 2.

By tensor product, the arrow c defines, by means of (2.2.1), arrows

$$c_i : \mu_S^{\otimes -i}[-2i] \longrightarrow Rp_*(A_P),$$

for every integer $i \geq 1$, and we agree to denote by c_0 the adjunction arrow

$$A_S \longrightarrow Rp_*(A_P).$$

Thus one defines an arrow

$$\gamma = \bigoplus_{i=0}^{r} c_i : \bigoplus_{i=0}^{r} \mu_S^{\otimes -i}[-2i] \longrightarrow Rp_*(A_P)$$

of $D(S)$.

Theorem 2.2.1. The arrow γ is an isomorphism.

Once the arrow γ has been defined, (2.2.1) is equivalent to the following corollary.

Proposition 2.2.2. Under the preceding hypotheses, one has:

a)
$$R^{2i+1}p_*(A_P) = 0 \quad \text{for every } i \in \mathbb{N}.$$

b) When $\bigoplus_i R^{2i}p_*(\mu_P^{\otimes i})$ is endowed with its A_S-algebra structure deduced from cup-product, the morphism of A_S-algebras
$$A_S[T] \longrightarrow \bigoplus_i R^{2i}p_*(\mu_P^{\otimes i})$$
defined by η has kernel the ideal (T^{r+1}) and hence defines an isomorphism of A_S-algebras
$$\theta : A_S[T]/(T^{r+1}) \xrightarrow{\sim} \bigoplus_i R^{2i}p_*(\mu_P^{\otimes i}).$$

c) The morphism

$$A_S \longrightarrow R^{2r}p_*(\mu^{\otimes r})$$

obtained by composing θ with the restriction to A_S of multiplication by T^r on $A_S[T]/(T^{r+1})$ is the inverse of the trace morphism (SGA 4 XVIII)

$$R^{2r}p_*(\mu^{\otimes r}) \longrightarrow A_S;$$

in other words,

$$\mathrm{Tr}(\eta^r) = 1.$$

Proof. Since the data are stable under base change, the proper base-change theorem (SGA 4 XII 5.1) and compatibility of the trace morphism with base change (SGA 4 XVIII) allow one to reduce to checking the analogous assertion on the fibres of P. In other words, one may suppose that S is the spectrum of a separably closed field k and that p is the canonical morphism $\mathbb{P}^r_k \to k$. In this case, the proof uses the following lemma.

Lemma 2.2.3. Let k be a separably closed field and let $p : \mathbb{P}^r_k \to k$ be the canonical projection. Then:

a)

$$R^{2i+1}p_*(A_P) = 0 \quad \text{for every } i.$$

b)

$$R^{2i}p_*(A_P) \simeq A_k \quad \text{for } i \in [0, r], \qquad R^{2i}p_*(A_P) = 0 \quad \text{if } i > r.$$

The lemma, manifestly true for $r = 0$, is proved by induction on r. Suppose therefore that it is true for $r-1$ and prove it for r. The projective space $\mathbb{P}^{r-1}_k$ embeds as a closed subspace in $\mathbb{P}^r_k$ with complement the open $\mathbb{E}^r_k$, whence an exact sequence of cohomology with proper supports

$$\cdots \longrightarrow H^i_!(\mathbb{E}^r_k) \longrightarrow H^i(\mathbb{P}^r_k) \longrightarrow H^i(\mathbb{P}^{r-1}_k) \longrightarrow H^{i+1}_!(\mathbb{E}^r_k) \longrightarrow \cdots .$$

The computation of cohomology with proper supports of $\mathbb{E}^r_k$ (1.1) shows that, if $i \neq (2r, 2r-1)$, the inverse-image map

$$H^i(\mathbb{P}^r_k) \longrightarrow H^i(\mathbb{P}^{r-1}_k)$$

is an isomorphism, whence the assertion in this case. If $i = 2r-1$, one similarly sees that $H^{2r-1}(\mathbb{P}^r_k)$ is contained in $H^{2r-1}(\mathbb{P}^{r-1}_k)$, hence is zero by the induction hypothesis. Finally, if $i = 2r$, the relations

$$H^{2r-1}(\mathbb{P}^{r-1}_k) = H^{2r}(\mathbb{P}^{r-1}_k) = 0$$

show that

$$H^{2r}_!(\mathbb{E}^r_k) \xrightarrow{\sim} H^{2r}(\mathbb{P}^r_k),$$

whence the assertion by (1.1).

The lemma implies part a) of 2.2.1. We now prove that θ is an isomorphism. The morphism θ may be interpreted as a morphism of rings

$$A[T]/(T^{r+1}) \longrightarrow \bigoplus_i H^{2i}(P, \mu^{\otimes i}).$$

Thus, by (2.2.3), the assertion will be proved if one shows that, for every $i \in [0, r]$, ξ^i is a free element of the A-module $H^{2i}(P, \mu^{\otimes i})$. It is enough to check this for ξ^r, which will be an immediate consequence of 2.2.2 c).

We now prove part c). In practice, this is the definition of the trace morphism in this situation; in any case, it expresses the compatibility of the trace morphism and the fundamental class in the diagram

$$\begin{array}{ccc} x_0 & \xrightarrow{\text{inj}} & \mathbb{P}^r_k \\ & \searrow & \downarrow p \\ & & k, \end{array}$$

where $\text{inj} : x_0 \to \mathbb{P}^r_k$ is the injection of a closed point of $\mathbb{P}^r_k$.

Corollary 2.2.4. Let L be a complex of A_S-modules. The arrow

$$\mathrm{R}\Gamma(S, \gamma \overset{\mathrm{L}}{\otimes}_A \mathrm{id}(L)) : \bigoplus_{i=0}^{r} \mathrm{R}\Gamma(S, L \otimes \mu_S^{\otimes -i})[-2i] \longrightarrow \mathrm{R}\Gamma(P, p^*(L))$$

is an isomorphism.

Indeed, it is enough to apply the functor $\mathrm{R}\Gamma_S$ to the isomorphism $\gamma \overset{\mathrm{L}}{\otimes}_A \mathrm{id}_L$.

2.2.5

To state the next corollary, for every scheme X we shall put

$$A^*(X) = \bigoplus_i H^{2i}(X, \mu_X^{\otimes i})$$

and shall use this notation systematically in what follows.

Corollary 2.2.6. The inverse-image homomorphism

$$p^* : A^*(S) = \bigoplus_i H^{2i}(S, \mu_S^{\otimes i}) \longrightarrow \bigoplus_i H^{2i}(P, \mu_P^{\otimes i}) = A^*(P)$$

is an injective morphism of unital rings, and the elements $1, \xi, \ldots, \xi^r$ form a basis of the $A^*(S)$-module $A^*(P)$. In particular, $A^*(P)$ is a free $A^*(S)$-module of the same rank as E.

3. Chern Classes

Let S be a scheme and let E be a locally free $\mathcal{O}_S$-module of constant rank r. Denoting by $\check{E}$ the dual of E, put $P = P_S(\check{E})$. We have seen (2.2.6) that, if ξ denotes the class of $\mathcal{O}_P(1)$ in $H^2(P, \mu)$, then the $A^*(S)$-module $A^*(P)$ is free with basis $1, \xi, \ldots, \xi^{r-1}$. In particular, it is immediate for reasons of homogeneity that there exists a unique relation of the form

$$\xi^r + c_1 \xi^{r-1} + \cdots + c_i \xi^{r-i} + \cdots + c_r = 0, \tag{3.1}$$

with $c_i \in H^{2i}(S, \mu^{\otimes i})$ for every $i \in [0, r]$.

Now let E be any locally free $\mathcal{O}_S$-module. For every integer r, the set S_r of points of S at which E has rank r is open. Thus one obtains a partition

$$S = \coprod_r S_r$$

of S into disjoint opens; in particular, for every A_S-module M and every integer i, the product of the inverse-image morphisms

$$H^i(S, M) \longrightarrow \prod_r H^i(S_r, M/S_r)$$

is a bijection.

The preceding considerations justify the following definition.

Definition 3.2. Let S be a scheme and E a locally free $\mathcal{O}_S$-module. For every integer $i \geq 0$, the i-th Chern class of E, denoted $c_i(E)$, is the element of $H^{2i}(S, \mu^{\otimes i})$ whose restriction, for every integer $r \geq 0$, to the open subset S_r of S consisting of the points where E has rank r, is the element c_i defined by relation 3.1. If the rank of E is bounded, the total Chern class of E is the element

$$c(E) = \sum_i c_i(E)$$

of $A^*(S)$; in the general case, this denotes the corresponding element of

$$\widehat{A}^*(S) = \prod_i A^i(S).$$

3.3

It is evident that, for all S and E, $c_0(E) = 1$, and that, if the rank of E is bounded by d, then $c_i(E) = 0$ for $i > d$.

Proposition 3.4. The Chern classes just defined satisfy the following properties.

(i) *Normalization.* Let L be an invertible $\mathcal{O}_S$-module. If $[L]$ denotes the image of the class of L under the boundary morphism

$$H^1(S, \mathbb{G}_m) \longrightarrow H^2(S, \mu),$$

then

$$c(L) = 1 + [L].$$

(ii) *Stability under base change.* Let $f : S' \to S$ be a morphism of schemes and let E be a locally free $\mathcal{O}_S$-module. For every integer i,

$$f^*(c_i(E)) = c_i(f^*E).$$

(iii) *Additivity.* Let

$$0 \to E' \to E \to E'' \to 0$$

be an exact sequence of locally free $\mathcal{O}_S$-modules. For every integer n, one has

$$c_n(E) = \sum_{i+j=n} c_i(E')c_j(E'').$$

Before beginning the proof, we extract the following corollary.

Corollary 3.5. For every exact sequence $0 \to E' \to E \to E'' \to 0$ of locally free $\mathcal{O}_S$-modules, one has

$$c(E) = c(E')c(E'')$$

in $\widehat{A}^*(S)$.

Proof of 3.4. Following A. Grothendieck: *La théorie des classes de Chern*, Bull. S.M.F. (1958), pp. 137–154.

(i) Let E be a locally free $\mathcal{O}_S$-module; put $P = P_S(\check{E})$ and let $p : P \to S$ be the canonical projection. Recall that there is a canonical surjective homomorphism

$$p^*(\check{E}) \longrightarrow \mathcal{O}_P(1).$$

In particular, if E is invertible and we put $E = L$, in agreement with the notation of (i), then $P = S$ and there is an isomorphism

$$L \xrightarrow{\sim} \mathcal{O}_P(1).$$

Therefore $\xi + [L] = 0$, and the assertion follows from the definition of Chern classes.

(ii) Immediate verification, left to the reader.

(iii) By using a partition of S into opens on which the modules in question have constant rank, we may suppose that E, E', E'' have constant ranks r, r', r'', respectively. Suppose that the following lemma has been proved; we show how it implies the assertion.

Lemma 3.6. Let E be a locally free $\mathcal{O}_S$-module endowed with a finite filtration

$$0 = E_0 \subset E_1 \subset \cdots \subset E_i \subset \cdots \subset E_r = E$$

whose consecutive quotients $L_i = E_i/E_{i-1}$ $(1 \leq i \leq r)$ are invertible. Then

$$c(E) = (1 + [L_1])(1 + [L_2]) \cdots (1 + [L_r]).$$

Let $h : Z \to S$ be the fibre product of the flag schemes of E' and E''. By the definition of flag schemes, it is clear that $h^*(E')$ and $h^*(E'')$ admit finite filtrations with invertible quotients (L'_i) $(1 \leq i \leq r')$ and (L''_j) $(1 \leq j \leq r'')$, respectively. It follows that $h^*(E)$ admits a filtration with consecutive quotients the L'_i and the L''_j. Applying Lemma 3.6 then shows that

$$c(h^*(E)) = \prod_{1 \leq i \leq r'} c(L'_i) \prod_{1 \leq j \leq r''} c(L''_j) = c(h^*(E'))c(h^*(E'')),$$

hence, by (ii),

$$h^*(c(E)) = h^*(c(E')c(E'')). \tag{3.5.1}$$

But h is a composite of morphisms of the form

$$P_T(F) \longrightarrow T \qquad (F \text{ locally free } \mathcal{O}_T\text{-module}),$$

so by (2.2.5) the inverse-image homomorphism $h^* : A^*(S) \to A^*(Z)$ is injective. This gives the desired assertion by (3.5.1).

We prove Lemma 3.6. By the preceding argument, it is enough to prove the analogous relation

$$c(p^*E) = \prod_i c(p^*(L_i)),$$

where, recall, $p : P = P_S(\check{E}) \to S$ is the canonical projection. For every $i \in [1, r]$, the monomorphism $E_i \to E$ defines by duality an epimorphism $\check{E} \to \check{E}_i$; putting $Y_i = P_S(\check{E}_i)$, one obtains a sequence of closed subschemes of P:

$$S \simeq Y_1 \subset Y_2 \subset \cdots \subset Y_i \subset \cdots \subset Y_r = P.$$

For every pair (i, j) of integers with $1 \leq i \leq j \leq r$, let

$$\alpha_{ji} : Y_i \to Y_j$$

be the canonical closed immersion, and put $\alpha_i = \alpha_{r,i}$. For every integer $i \in [1, r-1]$, it follows from the evident lemma (3.6.1) below that Y_i is defined in Y_{i+1} by an invertible ideal isomorphic to

$$\alpha_{i+1}^*(p^*(\check{L}_{i+1}) \otimes \mathcal{O}_P(-1)).$$

Lemma 3.6.1. Let $0 \to L \to E \to F \to 0$ be an exact sequence of locally free $\mathcal{O}_S$-modules. Then the sequence

$$0 \to L \otimes_S S(E) \xrightarrow{u} S(E) \xrightarrow{v} S(F) \to 0,$$

where v denotes the evident morphism and u is the degree-one morphism corresponding to the inclusion of L in E, is an exact sequence of graded $\mathcal{O}_S$-modules.

Moreover, Y_1 is identified with S and we have an isomorphism

$$\alpha_1^*(p^*(\check{L}_1)) \simeq \mathcal{O}_{Y_1}(1),$$

i.e.

$$\alpha_1^*(p^*(\check{L}_1) \otimes \mathcal{O}_P(-1)) \simeq \mathcal{O}_{Y_1}. \tag{3.6.2}$$

We shall be able to conclude by using the following two properties of the Gysin homomorphism (SGA 4 XVIII) associated with a closed immersion $u : Z \to X$ of smooth S-schemes defined by an ideal J of $\mathcal{O}_X$. It satisfies the projection formula

$$u_*(x\, u^*(y)) = u_*(x)y, \tag{3.6.3}$$

and, if the ideal J is invertible, the relation

$$u_*(1_Z) = -[J] = [\check{J}]. \tag{3.6.4}$$

Indeed, from this we shall prove, by induction increasing on the integer i, that

$$(\alpha_i)_*(\alpha_i)^*\Big(\prod_{j\leq i}[p^*(\check{L}_j)\otimes\mathcal{O}_P(-1)]\Big)=0. \tag{3.6.5}$$

For $i=r$, assertion (3.6.5) says

$$\prod_i[p^*(\check{L}_i)\otimes\mathcal{O}_P(-1)]=0,$$

or equivalently

$$\prod_i(\xi+c_1(p^*(\check{L}_i)))=0,$$

which immediately gives (3.6). Assertion (3.6.5) for $i=1$ follows from (3.6.2). Suppose it true for i and prove it for $i+1$. For simplicity put

$$N=\prod_{j\leq i}[p^*(\check{L}_j)\otimes\mathcal{O}_P(-1)].$$

The equality (3.6.5) for i can also be written

$$(\alpha_{i+1})_*(\alpha_{i+1,i})_*(\alpha_{i+1,i})^*(\alpha_{i+1})^*(N)=0,$$

hence, in view of the projection formula for $\alpha_{i+1,i}$,

$$(\alpha_{i+1})_*\big[(\alpha_{i+1})^*(N)(\alpha_{i+1})^*(p^*(\check{L}_{i+1})\otimes\mathcal{O}_P(-1))\big]=0,$$

which is exactly the desired result.

Corollary 3.7.

(i) For every locally free $\mathcal{O}_S$-module E and every integer i,

$$c_i(\check{E})=(-1)^ic_i(E).$$

(ii) If E is a locally free $\mathcal{O}_S$-module of rank r, then

$$c_1(E)=c_1(\Lambda^rE).$$

(iii) More generally, the Chern classes of a tensor product or of an exterior power are expressed by means of the universal polynomials made explicit in (SGA 6 V 6.1).

Proof. We prove, for example, (ii); the other assertions are seen similarly. Using the flag scheme of E, one reduces to the case where E admits a filtration with invertible quotients L_i. The assertion then follows from the well-known isomorphism

$$\Lambda^r(E)\simeq\bigotimes_i L_i.$$

3.8

Given a scheme X locally of finite type over $\mathrm{Spec}(\mathbb{C})$, the set $X(\mathbb{C})$ of its rational points is canonically endowed with the structure of a locally compact topological space. Thus, by algebraic topology, one has a theory of Chern classes [3], assigning to every continuous complex vector bundle V on $X(\mathbb{C})$ classes $c_i(V) \in H^{2i}(X(\mathbb{C}), \mathbb{Z})$. Now let $\mathcal{O}_{\mathbb{C}}$ be the sheaf of continuous complex-valued functions on $X(\mathbb{C})$, and let $\mathcal{E}$ be a locally free $\mathcal{O}_{\mathbb{C}}$-module of finite type. One defines Chern classes

$$c_i(\mathcal{E}) \in H^{2i}(X(\mathbb{C}), \mathbb{Z}),$$

namely those of the complex vector bundle whose sheaf of continuous sections is $\mathcal{E}$. Finally, using the evident map $\mathbb{Z} \to \mathbb{Z}/\nu\mathbb{Z}$, one obtains Chern classes, denoted by the same symbol when no confusion is possible,

$$c_i(\mathcal{E}) \in H^{2i}(X(\mathbb{C}), \mathbb{Z}/\nu\mathbb{Z}). \tag{3.8.1}$$

On the other hand, when $X_{\text{ét}}$ is equipped with its structural sheaf $\mathcal{O}_a$ and $X(\mathbb{C})$ with the ring $\mathcal{O}_{\mathbb{C}}$, there is a morphism of ringed topoi (SGA 4 XI)

$$\varepsilon : X(\mathbb{C}) \to X_{\text{ét}},$$

the structural morphism of rings

$$\varepsilon^*(\mathcal{O}_a) \to \mathcal{O}_{\mathbb{C}} \tag{3.8.2}$$

coming from the fact that every algebraic function is continuous. The morphism ε induces a morphism of abelian sheaves

$$\varepsilon^*(\mu_{X_{\text{ét}}}) \to \mu_{X(\mathbb{C})}, \tag{3.8.3}$$

where the letter μ denotes, in each of the two contexts, the sheaf of ν-th roots of unity. Finally, we shall canonically identify $(\mathbb{Z}/\nu\mathbb{Z})_{X(\mathbb{C})}$ and $\mu_{X(\mathbb{C})}$ by means of the isomorphism

$$(\mathbb{Z}/\nu\mathbb{Z})_{X(\mathbb{C})} \xrightarrow{\sim} \mu_{X(\mathbb{C})} \tag{3.8.4}$$

sending the section 1 to the section $e^{2i\pi/\nu}$.

Proposition 3.8.5. Let E be a locally free $\mathcal{O}_X$-module. For every integer $i \geq 0$, let

$$\varepsilon^* : H^{2i}(X_{\text{ét}}, \mu_X^{\otimes i}) \to H^{2i}(X(\mathbb{C}), \mathbb{Z}/\nu\mathbb{Z})$$

be the inverse-image morphism deduced from 3.8.3 and 3.8.4. Then

$$c_i(\varepsilon^* E) = \varepsilon^* c_i(E).$$

Proof. It is enough to check this when E is invertible. Then, with the usual identifications, $\varepsilon^*(E)$ is the image of E under the canonical map

$$\varepsilon^* : H^1(X_{\text{ét}}, \mathbb{G}_m) \to H^1(X(\mathbb{C}), \mathcal{O}_{\mathbb{C}}^*), \tag{3.8.6}$$

and one has to see that the diagram

$$\begin{array}{ccc} H^1(X, \mathbb{G}_m) & \xrightarrow{\varepsilon^*} & H^1(X(\mathbb{C}), \mathcal{O}_{\mathbb{C}}^*) \\ \downarrow{\scriptstyle \partial} & & \downarrow{\scriptstyle c_1} \\ H^2(X, \mu_X) & \xrightarrow[\varepsilon^*]{} & H^2(X(\mathbb{C}), \mathbb{Z}/\nu\mathbb{Z}) \end{array} \tag{3.8.7}$$

where ∂ is the boundary morphism coming from the canonical exact sequence

$$0 \to \mu_X \to \mathbb{G}_m \xrightarrow{\nu} \mathbb{G}_m \to 0 \tag{3.8.8}$$

and c_1 is the first Chern class (3.8.1), is commutative. In fact, using that the morphism "first Chern class"

$$H^1(X(\mathbb{C}), \mathcal{O}^*_{\mathbb{C}}) \to H^2(X, \mathbb{Z})$$

is the boundary morphism of the canonical exact sequence

$$0 \to \mathbb{Z} \to \mathcal{O}_{\mathbb{C}} \xrightarrow{\exp} \mathcal{O}^*_{\mathbb{C}} \to 0, \qquad t \mapsto 2i\pi t,$$

one easily sees that the morphism c_1 of (3.8.7) is nothing other than the boundary morphism associated with the exact sequence

$$0 \to \mathbb{Z}/\nu\mathbb{Z} \to \mathcal{O}^*_{\mathbb{C}} \xrightarrow{\nu} \mathcal{O}^*_{\mathbb{C}} \to 0, \qquad t \mapsto e^{2i\pi t/\nu},$$

which, in view of (3.8.4), is the analogue of (3.8.8). The assertion follows at once.

3.9

Let X be a scheme and E a locally free $\mathcal{O}_X$-module. Immediate passage to the limit allows one to define, for every prime number ℓ prime to the residual characteristics of X, ℓ-adic Chern classes

$$c_i(E) \in H^{2i}(X, \mathbb{Z}_\ell(i)) \overset{\text{def}}{=} \varprojlim_{\nu} H^{2i}(X, \mu_{\ell^\nu}^{\otimes i}),$$

which have the usual properties made explicit in 3.4 and 3.7 and which, in the context of 3.8, are manifestly compatible, in an evident sense, with the Chern classes defined topologically.

Tensoring by $\mathbb{Q}_\ell$, one obtains ℓ-adic Chern classes modulo torsion

$$c_i(E) \in H^{2i}(X, \mathbb{Q}_\ell(i)) = H^{2i}(X, \mathbb{Z}_\ell(i)) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell,$$

which manifestly satisfy the same properties.

Now suppose that X is a quasi-projective smooth scheme over a field k, and denote here by $C^*(X)$ its Chow ring (Sém. Chevalley: Anneaux de Chow et applications III 4). Recall that in IV we defined a morphism of graded rings

$$\varphi_X : C^*(X) \to A^*(X)$$

compatible with direct-image and inverse-image morphisms. Moreover, the canonical isomorphism

$$\varepsilon_X : \mathrm{Pic}(X) \xrightarrow{\sim} C^1(X)$$

which sends every invertible $\mathcal{O}_X$-module L to the class of the divisor of a rational section of L not vanishing on any connected component of X, gives, on the model of the aforementioned article of Grothendieck, where k was assumed algebraically closed, a theory of Chern classes with values in $C^*(X)$. The composite

$$\varphi_X \circ \varepsilon_X : \mathrm{Pic}(X) \longrightarrow H^2(X, \mathbb{Z}_\ell(1))$$

is just the first ℓ-adic Chern class. Indeed, it is enough to check this on elements of $\mathrm{Pic}(X)$ of the form $\check{J}$, with J an invertible ideal of $\mathcal{O}_X$, and then this follows from (3.6.4). By the uniqueness properties of theories of Chern classes, it follows that the morphism φ_X sends Chern classes to Chern classes.

4. Self-intersection Formula and Applications

Let S be a scheme, X an S-scheme, and Y a closed subscheme of X, smooth over S and everywhere of codimension d. Finally suppose that X is smooth over S in a neighbourhood of Y. Let $i : Y \to X$ be the canonical closed immersion and J the ideal of $\mathcal{O}_X$ defining Y. Recall (SGA $4^{1/2}$ Cycle) that in this case one has Gysin isomorphisms

$$i_* : H^{2p}(Y, \mu_Y^{\otimes p}) \to H_Y^{2p+2d}(X, \mu_X^{\otimes(p+d)}),$$

namely cup-products with the fundamental class. If no confusion is possible, we shall denote by the same symbol the Gysin morphisms

$$i_* : H^{2p}(Y, \mu_Y^{\otimes p}) \to H^{2p+2d}(X, \mu_X^{\otimes(p+d)})$$

obtained from the preceding ones by forgetting supports.

Theorem 4.1. In the preceding situation, if

$$N = J/J^2$$

denotes the normal sheaf of i, then for every $y \in A^*(Y)$ one has

$$i^* i_*(y) = y\, c_d(\check{N}).$$

Before beginning the proof of this theorem, we indicate a few variants, proved in exactly the same way.

a) If ℓ is a prime number prime to the residual characteristics of S, the analogous formula is true in $H^*(Y, \mathbb{Z}_\ell(*))$.

b) One may put in supports. If, for example, T is a closed subset of Y and $y \in H_T^{2p}(Y, \mu_Y^{\otimes p})$, formula 4.1 is still true in $H_T^{2p+2d}(Y, \mu_Y^{\otimes(p+d)})$. Of course, i_* then denotes the Gysin morphism

$$H_T^{2p}(Y, \mu_Y^{\otimes p}) \to H_T^{2p+2d}(X, \mu_X^{\otimes(p+d)}),$$

which is again an isomorphism (SGA $4^{1/2}$ Cycle).

c) Finally, the two cases may be combined.

Since the fundamental tool in the proof of 4.1 is the theory of blown-up schemes, we now recall a few facts about it. Let

$$f : X' \to X$$

be the X-scheme obtained by blowing up Y, and let

$$\begin{array}{ccc} Y' & \xrightarrow{j} & X' \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle f} \\ Y & \xrightarrow[i]{} & X \end{array}$$

be the cartesian diagram constructed from f and i. Recall (cf. SGA 6 VII 3.1, whose notation we adopt) that j is a regular immersion of codimension 1 defined by an ideal

$$J' \simeq \mathcal{O}_{X'}(1)$$

and that $Y' \simeq P_Y(N)$. Moreover, one has an exact sequence of $\mathcal{O}_{Y'}$-modules

$$0 \to F \to g^*(N) \to \mathcal{O}_{Y'}(1) \to 0.$$

Lemma 4.2. For every A_X-module M, the homomorphisms

$$f^* : H^*_Y(X, M) \to H^*_{Y'}(X', f^*(M))$$

and

$$f_* : H^*_{Y'}(X', f^*(M)) \to H^*_Y(X, M)$$

are related by $f_* f^* = \mathrm{id}$. Moreover, f_* has degree 0.

Proof. Since f is a complete-intersection morphism of relative dimension zero (SGA 6 VII 1.8), the last assertion follows from the definition of the Gysin homomorphism (SGA $4^{1/2}$ Cycle). For the first, the projection formula for f,

$$f_*(x\, f^*(x')) = f_*(x)x',$$

where $x \in H^*(X, A)$ and $x' \in H^*_Y(X, M)$, reduces the claim to proving that $f_*(1) = 1$. It is enough to check the analogous assertion over $U = X - Y$, which is evident because f induces an isomorphism from $U' = X' - Y'$ onto U.

Remark 4.3. Of course, the analogue of 4.2 obtained by eliminating supports is also true and is proved in the same way.

We now come to the proof of 4.1. First, by a general result of (SGA $4^{1/2}$ Cycle), which is proved in an essentially formal way, one has

$$i^* i_*(y) = y\, i^* i_*(1),$$

so it is enough to prove

$$i^* i_*(1_Y) = c_d(\check{N}),$$

where i_* here denotes the Gysin isomorphism

$$H^0(Y, A_Y) \to H^{2d}_Y(X, \mu_X^{\otimes d}).$$

Since $f^* i_* 1_Y \in H^{2d}_{Y'}(X', \mu_{X'}^{\otimes d})$, and since the Gysin morphism

$$j_* : H^{2d-2}(Y', \mu_{Y'}^{\otimes(d-1)}) \to H^{2d}_{Y'}(X', \mu_{X'}^{\otimes d})$$

is an isomorphism, there exists

$$u \in H^{2d-2}(Y', \mu_{Y'}^{\otimes(d-1)})$$

such that

$$f^* i_*(1_Y) = j_*(u). \tag{4.1.1}$$

Applying j^* to both sides of 4.1.1, one obtains

$$j^* f^* i_*(1_Y) = j^* j_*(u).$$

Putting $\xi = c_1(\mathcal{O}_{Y'}(1))$, it follows from 3.6.4 that

$$g^* i^* i_*(1_Y) = -u\,\xi. \tag{4.1.2}$$

The element u admits a unique decomposition of the form

$$u = a_0 + a_1\xi + \cdots + a_{d-1}\xi^{d-1}, \qquad a_i \in H^{2d-2-2i}(Y, \mu_Y^{\otimes(d-1-i)}). \tag{4.1.3}$$

In view of the defining relation for the Chern classes of $\check{N}$,

$$\xi^d + c_1(\check{N})\xi^{d-1} + \cdots + c_{d-1}(\check{N})\xi + c_d(\check{N}) = 0, \tag{4.1.4}$$

we deduce the equality

$$u\xi = -a_{d-1}c_d(\check{N}) + (a_0 - a_{d-1}c_{d-1}(\check{N}))\xi + \cdots + (a_{d-2} - a_{d-1}c_1(\check{N}))\xi^{d-1}.$$

Comparing this last expression with (4.1.2), and using the injectivity of g^* (2.2.6), one obtains

$$i^* i_*(1_Y) = a_{d-1}c_d(\check{N}). \tag{4.1.5}$$

It remains to determine a_{d-1}. First, the homomorphism g_* lowers degrees by $2d-2$, hence

$$g_*(\xi^i) = 0 \quad (0 \leq i \leq d-2),$$

and moreover (2.2.2)

$$g_*(\xi^{d-1}) = 1.$$

Applying g_* to both sides of 4.1.3, we obtain

$$g_*(u) = a_{d-1}. \tag{4.1.6}$$

On the other hand, applying f_* to both sides of 4.1.1, we obtain, in view of 4.2,

$$i_*(1_Y) = i_* g_*(u). \tag{4.1.7}$$

But the homomorphism i_* in question is injective; hence

$$a_{d-1} = g_*(u) = 1_Y,$$

which completes the proof.

Remarks 4.4. a) The essential ingredient in what precedes is the purity theorem. Once it is available in full generality, statement 4.1 will be valid with Y regular and purely of codimension d in X, and X excellent and regular in a neighbourhood of Y. In this form, the result is in any case established in characteristic 0, by (SGA 4 XIX).

b) When S is the spectrum of a separably closed field and X and Y are quasi-projective and smooth over S, the analogous statement in the Chow ring of Y was established by Mumford (cf. 9.2).

Corollary 4.5. Under the hypotheses of 4.1, let x and y belong to $A^*(Y)$. Then

$$i_*(x)i_*(y) = i_*(xy\, c_d(\check{N})).$$

Proof. The projection formula for the morphism i shows that

$$i_*(x)i_*(y) = i_*(x\, i^*i_*(y)),$$

and the conclusion follows from 4.1.

Corollary 4.6. Let S be a scheme, let E be a locally free $\mathcal{O}_S$-module of constant rank r, and let $g : X = V(\check{E}) \to S$ be the vector bundle whose sheaf of sections is E. For every section f of X over S, one has

$$f_*(1_S) = g^*(c_r(E))$$

in $H^{2r}(X, \mu_X^{\otimes r})$.

Proof. Since g^* is an isomorphism (1.2) and $g \circ f = \mathrm{id}$, f^* is bijective. It is therefore enough to check that

$$f^*f_*(1_S) = f^*g^*(c_r(E)).$$

If N denotes the normal sheaf of f, this last equality is equivalent, by 4.1, to

$$c_r(\check{N}) = c_r(E).$$

In fact one even has an isomorphism $\check{N} \simeq E$, since the exact sequence of (EGA IV 17.2.5), applied to the situation

$$S \xrightarrow{f} X \xrightarrow{g} S,$$

gives an isomorphism $N \simeq f^*\Omega^1_{X/S}$, and moreover $\Omega^1_{X/S} \simeq g^*\check{E}$ (EGA IV 16.4.8).

Corollary 4.7. Under the hypotheses of 4.6, assume in addition that S is smooth and quasi-projective over a separably closed field. Let σ_X denote the zero-section cycle of X, and let $Y = f^{-1}(\sigma_X)$ be the cycle of zeros of f. Then

$$\mathrm{cl}_S(Y) = c_r(E)$$

in $H^{2r}(S, \mu_S^{\otimes r})$.

Proof. By IV,

$$\mathrm{cl}_S(Y) = f^* \mathrm{cl}_X(\sigma_X).$$

Let s_0 be the zero-section morphism of X. Then

$$\mathrm{cl}_X(\sigma_X) \overset{\text{dfn}}{=} (s_0)_*(1_S) \overset{(4.6)}{=} g^*(c_r(E)),$$

and the assertion follows by applying f^* to the extreme terms.

Remark 4.8. Let ℓ be a prime number distinct from the residual characteristics of S. By simple passage to the projective limit, one deduces from 4.6 and 4.7 the corresponding statements in ℓ-adic cohomology.

Now let ℓ be a prime number and let X be a proper scheme over a separably closed field k of characteristic prime to ℓ. Recall (IV) that the ℓ-adic Euler-Poincaré characteristic of X is the integer

$$\mathrm{EP}_\ell(X) = \sum_i (-1)^i \dim H^i(X, \mathbb{Q}_\ell).$$

Corollary 4.9. Let X be a smooth, proper, connected scheme of dimension n over a separably closed field k, with $\mathrm{char}(k) \neq \ell$. If $p : X \to k$ denotes the canonical projection, then

$$\mathrm{EP}_\ell(X) = p_* c_n(\check{\Omega}^1_X)$$

in $\mathbb{Q}_\ell = H^0(k, \mathbb{Q}_\ell)$.

Proof. Let $j : X \to X \times X$ be the diagonal immersion of X, and let $q : X \times X \to k$ be the canonical projection. Applying 4.1 to the morphism j gives

$$c_n(\check{\Omega}^1_X) = j^* j_*(1_X),$$

hence

$$p_*(c_n(\check{\Omega}^1_X)) = p_* j^* j_*(1_X) = q_* j_* j^* j_*(1_X).$$

Using the projection formula for j, one deduces

$$p_*(c_n(\check{\Omega}^1_X)) = q_*(j_*(1_X) \cup j_*(1_X)),$$

where, by IV, the second member is equal to the ℓ-adic Euler-Poincaré characteristic of X.

4.10

When X is projective over k, the result recalled from IV shows that $\mathrm{EP}_\ell(X)$ is, in the Chow ring of $X \times X$, the self-intersection of the diagonal cycle, and consequently is independent of the prime number $\ell \neq \mathrm{char}(k)$. We shall therefore be able to speak of the Euler-Poincaré characteristic $\mathrm{EP}(X)$ of X, without reference to the integer ℓ.

Proposition 4.11. Let X be a smooth, projective, connected scheme of dimension n over a separably closed field k. Then

$$\mathrm{EP}(X) = \sum_{p,q} (-1)^{p+q} \dim H^p(X, \Omega^q_X).$$

Proof. We use the notation of the proof of 4.9, and let J be the ideal of the diagonal immersion of X. As observed in 4.10, $\mathrm{EP}(X)$ is, in the Chow ring of $X \times X$, the intersection product $\Delta \cdot \Delta$ of the diagonal cycle Δ with itself. To compute it, one may neglect torsion and therefore work in $\mathrm{Gr}^\bullet_{\mathrm{top}}(X)$. This shows that $\mathrm{EP}(X)$ is the image under the direct-image morphism

$$q_* : K(X \times X) \to K(k) = \mathbb{Z}$$

of the square of the class of $\mathcal{O}_{X \times X}/J$. But, by (SGA 6 VII 2.5), this square is equal to

$$\sum_i (-1)^i \lambda^i([\Omega^1_X]),$$

and the desired formula follows immediately, by the definition of q_*.

5. Flag Schemes

Let S be a scheme, let E be a locally free $\mathcal{O}_S$-module of rank r, and let $(p_i)_{1\leq i\leq m}$ be m integers >0 satisfying

$$p_1 + p_2 + \cdots + p_m = r.$$

Recall that a flag of type $(p_1, \ldots, p_m)$ of E is a finite filtration

$$0 = E_m \subset E_{m-1} \subset \cdots \subset E_0 = E$$

of E such that, for every integer $i \in [1, m]$, the quotient E_{i-1}/E_i is locally free of rank p_i.

One defines a functor $(\mathrm{Sch}\,/S)^\circ \to (\mathrm{Ens})$ by assigning to an S-scheme $u : T \to S$ the set of flags of type $(p_1, \ldots, p_m)$ of $u^*(E)$, and to a morphism of S-schemes the inverse image, in the evident sense, on flags. It is proved (EGA I, 2nd edition) that this functor is representable, and any representative is called an S-scheme of flags of type $(p_1, \ldots, p_m)$ of E.

In what follows, $f : X \to S$ will denote the S-scheme of flags of type $(p_1, \ldots, p_m)$ of E. Moreover, the scheme of flags of type $(1, 1, \ldots, 1)$ of E will be denoted D and called the flag scheme of E, without further specification, if no confusion is possible.

It is clear from the definition that the $\mathcal{O}_X$-module $f^*(E)$ admits a canonical finite filtration

$$0 = F_m \subset F_{m-1} \subset \cdots \subset F_0 = f^*(E),$$

for which the quotient $E_i = F_{i-1}/F_i$ $(1 \leq i \leq m)$ is locally free of rank p_i. For every integer $i \in [1, m]$, let

$$g_i : D_i \to X$$

be the X-scheme of flags of E_i, and let $g : D_1 \times_X \cdots \times_X D_m \to X$ be the fibre product of the X-schemes D_i. It is clear that the composite

$$h = f \circ g : \prod_i D_i \to S \tag{5.1}$$

is S-isomorphic to the S-scheme of flags of E; up to S-isomorphism, one may therefore write

$$D = \prod_i D_i.$$

Proposition 5.2. In $D^b(S, A)$ there is an isomorphism

$$\mathrm{R}f_*(A) \simeq \bigoplus_i R^{2i} f_*(A)[-2i].$$

Proof. Since h is a composite of finitely many morphisms of the form

$$P_T(F) \to T \qquad (F \text{ a locally free } \mathcal{O}_T\text{-module}), \tag{Q}$$

it follows from (2.2.1) that

$$\mathrm{R}h_*(A) \simeq \bigoplus_j R^j h_*(A)[-j].$$

For the same reason, one also has

$$\mathrm{R}g_*(A) \simeq \bigoplus_j R^j g_*(A)[-j].$$

Using ([6] 2.16), one obtains an isomorphism

$$\mathrm{R}f_*(g_*A) \simeq \bigoplus_j R^j f_*(g_*A)[-j].$$

Since g is smooth with geometrically connected fibres, $A_X \simeq g_*(A_D)$; hence it remains to show that

$$R^{2i+1} f_*(A) = 0 \qquad (i \in \mathbb{N}). \tag{5.2.1}$$

For this, one immediately reduces, using conservativity of the system of fibre functors (SGA 4 VIII 3.5), to the case where S is the spectrum of a separably closed field k. Then, since g is a composite of projective bundles, (2.2.4) shows that the inverse-image map

$$H^{2i+1}(X, A_X) \to H^{2i+1}(D, A_D)$$

is a monomorphism, so one may suppose that $X = D$. In this case, since the projection $D \to k$ is itself a composite of projective bundles, the assertion follows by induction from (2.2.4).

Corollary 5.3. For every morphism of schemes $u : S \to T$, the Leray spectral sequence

$$E_2^{pq} = R^p u_*\, R^q f_*(A) \Rightarrow R^{p+q}(u \circ f)_*(A)$$

is degenerate.

Proof. Cf. [6] 1.2.

We shall now specify the multiplicative structure of the cohomology of X, first examining a particular case. With the preceding notation, one obtains a morphism of rings

$$\alpha : A^*(S)[T_{ij_i}]_{1 \leq i \leq m,\, 1 \leq j_i \leq p_i} \to A^*(X)$$

by sending $A^*(S)$ into $A^*(X)$ by inverse image f^* and, for every pair (i, j_i), as above, sending the element T_{ij_i} to the j_i-th Chern class $c_{j_i}(E_i)$. For every integer p, one has, by (3.4 (iii)),

$$c_p(f^*E) = \sum_{i_1 + i_2 + \cdots + i_m = p} c_{i_1}(E_1) \cdots c_{i_m}(E_m),$$

so that, by functoriality of Chern classes, the morphism vanishes on the ideal J_X generated by the elements

$$c_p(E) - \sum_{i_1 + \cdots + i_m = p} T_{1,i_1} \cdots T_{m,i_m}$$

for varying p. Hence there is a morphism of rings

$$\varphi_X : \big(A^*(S)[T_{ij_i}]_{(i,j_i)}\big)/J_X \to A^*(X).$$

Proposition 5.4. The above morphism of rings φ_X is an isomorphism. The $A^*(S)$-module $A^*(X)$ is free of rank

$$\frac{r!}{p_1! p_2! \cdots p_m!}.$$

Proof. We follow Grothendieck's exposé (Séminaire Chevalley 1958, Anneaux de Chow et applications, Exp. IV). We shall need the following lemma (cf. Lemma 1, p. 19 of loc. cit.).

Lemma 5.4.1. a) Let R be a commutative ring, and let $(a_i)_{1\leq i\leq r}$ be r elements of R. Let σ_i be the i-th elementary symmetric function of the elements $(U_i)_{1\leq i\leq r}$, and let I be the ideal of the polynomial ring $R[U_1, U_2, \ldots, U_r]$ generated by the elements $\sigma_i - a_i$. Then the R-algebra

$$R[U_1, U_2, \ldots, U_r]/I$$

is a free R-module of rank $r!$.

b) Let $r, p_1, p_2, \ldots, p_m$ be integers > 0 satisfying $p_1 + \cdots + p_m = r$. Then the morphism of polynomial rings

$$V = R[T_{i,j_i}]_{1\leq i\leq m,\, 1\leq j_i\leq p_i} \longrightarrow R[U_i]_{1\leq i\leq r} = W$$

obtained by sending T_{i,j_i} to the j_i-th elementary symmetric function of the elements

$$(U_{p_1+\cdots+p_{i-1}+s})_{1\leq s\leq p_i}$$

is injective and makes W a free V-module of rank $p_1!\cdots p_m!$.

In particular, the morphism of R-algebras

$$R[T_1, \ldots, T_r] \to R[U_1, \ldots, U_r]$$

obtained by sending T_i to the i-th elementary symmetric function of the U_j is injective and makes the second member a free module of rank $r!$ over the first.

We show how (5.4.1) implies (5.4). First suppose that X is the scheme D of flags of E, and for simplicity put $T_{i1} = U_i$. Since the canonical projection $D \to S$ is a composite of $r-1$ morphisms of the form

$$P_{Y_i}(M_i) \to Y_i \quad (1 \leq i \leq r-1),$$

where M_i is a locally free $\mathcal{O}_{Y_i}$-module of rank $r-i+1$, it follows from (2.2.6) that $A^*(D)$ is a free $A^*(S)$-module of rank $r!$, and that the morphism φ_D is surjective. But Lemma 5.4.1 a) shows that the source of φ_D is also a free $A^*(S)$-module of rank $r!$; hence the assertion in the case $X = D$.

In the general case, it is clear that the diagram

$$\begin{array}{ccc} A^*(X) & \xrightarrow{\quad g^*\quad} & A^*(D) \\ {\scriptstyle\varphi_X}\uparrow & & \uparrow{\scriptstyle\varphi_D} \\ C = A^*(S)[T_{i,j_i}]/J_X & \xrightarrow[\gamma]{} & A^*(S)[U_k]/J_D \end{array}$$

commutes; here the map γ is obtained by passage to the quotient from the morphism of $A^*(S)$-algebras

$$A^*(S)[T_{i,j_i}] \to A^*(S)[U_k]$$

defined by sending T_{i,j_i} to the j_i-th elementary symmetric function of the elements

$$(U_{p_1+\cdots+p_{i-1}+s})_{1\leq s\leq p_i}.$$

Since φ_D is an isomorphism, 5.4.1 b) implies that $A^*(D)$ is a free C-module of rank $p_1!\cdots p_m!$. On the other hand, expressing g as a fibre product of X-schemes of flags shows that $A^*(D)$ is also a free $A^*(X)$-module of rank $p_1!\cdots p_m!$. It follows at once that φ_X is an isomorphism.

In the statement of the next proposition, we agree to put, for every scheme Y and every A_Y-module M,

$$Q(Y,M)=\bigoplus_{n,i} H^n(Y,M\otimes\mu_Y^{\otimes i}).$$

The A-module $Q(Y,M)$ is canonically endowed with a structure of $A^*(Y)$-module, coming from cup-product. If $u:Z\to Y$ is a morphism of schemes, the inverse-image morphism

$$u^*:Q(Y,M)\to Q(Z,u^*M)$$

is compatible with the $A^*(Y)$-module structure on $Q(Y,M)$ and the $A^*(Z)$-module structure on $Q(Z,u^*M)$. One deduces a morphism of $A^*(Z)$-modules, called canonical,

$$A^*(Z)\otimes_{A^*(Y)} Q(Y,M)\to Q(Z,u^*M).$$

Proposition 5.5. Let S be a scheme, and let E be a locally free $\mathcal{O}_S$-module of rank r. Let $f:X\to S$ be the S-scheme of flags of type $(p_1,\dots,p_m)$ of E. Then, for every A_S-module L, the canonical morphism

$$\alpha:A^*(X)\otimes_{A^*(S)} Q(S,L)\to Q(X,f^*L)$$

is an isomorphism.

Proof. When $X=P_S(E)$, this is an immediate consequence of (2.2.4) and (2.2.6). Hence it follows that it is true for $X=D$. In the general case, since the canonical morphisms $g:D\to X$ and $h:D\to S$ are composites of projective bundles, the canonical morphisms

$$A^*(D)\otimes_{A^*(S)} Q(S,L)\to Q(D,h^*L)$$

and

$$A^*(D)\otimes_{A^*(X)} Q(X,g^*L)\to Q(D,g^*L)$$

are isomorphisms. Consequently $\mathrm{id}_{A^*(D)}\otimes\alpha$ is an isomorphism, whence the result, since $A^*(D)$ is free over $A^*(X)$.

We shall now give a relative variant of (5.4) and (5.5). With the preceding notation, let $u:S\to T$ be a morphism of schemes. Put

$$A^*(X/T)=\bigoplus_i R^{2i}(u\circ f)_*(A_X)$$

and similarly

$$A^*(S/T)=\bigoplus_i R^{2i}u_*(A_S).$$

Finally, for every A_S-module L, put

$$Q(S/T,L)=\bigoplus_{n,i} R^n u_*(L\otimes\mu_S^{\otimes i})$$

and

$$Q(X/T,f^*L)=\bigoplus_{n,i} R^n(u\circ f)_*(f^*L\otimes\mu_X^{\otimes i}).$$

For every pair (i,j) of integers, with $1 \leq i \leq m$ and $1 \leq j \leq p_i$, the image of the Chern class $c_j(E_i)$ by the canonical morphism

$$H^{2j}(X, \mu_X^{\otimes j}) \to H^0(T, R^{2j}(u \circ f)_*(\mu_X^{\otimes j}))$$

defines an A_T-morphism

$$c_{ij} : A_T \to R^{2j}(u \circ f)_*(\mu_X^{\otimes j}).$$

The data of the c_{ij} and the inverse image f^* allow one to define a morphism of $A^*(S/T)$-algebras

$$\theta_1 : A^*(S/T)[T_{i,j_i}]_{(i,j_i)} \to A^*(X/T).$$

Denoting by c_i the sections of $A^*(S/T)$ defined by the Chern classes $c_i(E)$, one sees as in (5.4) that θ_1 vanishes on the ideal J locally generated by the relations

$$\sum_{i_1+\cdots+i_m=p} T_{1,i_1} \cdots T_{m,i_m} = c_p \qquad (p \in \mathbb{N}).$$

Hence there is a morphism of $A^*(S/T)$-algebras

$$\theta : A^*(S/T)[T_{i,j_i}]_{(i,j_i)}/J \to A^*(X/T).$$

Proposition 5.6. With the preceding notation:

a) The morphism of $A^*(S/T)$-algebras

$$\theta : A^*(S/T)[T_{i,j_i}]_{(i,j_i)}/J \to A^*(X/T)$$

is an isomorphism.

b) For every A_S-module L, the canonical morphism of $A^*(X/T)$-modules

$$A^*(X/T) \otimes_{A^*(S/T)} Q(S/T, L) \to Q(X/T, f^*L)$$

is an isomorphism.

Proof. Simple sheafification of (5.4) and (5.5), respectively.

6. Group Schemes

We begin with a general property of objects twisted by torsors.

Proposition 6.1. Let S be a scheme, G a quasi-compact smooth S-group scheme with connected fibres, and X an S-scheme endowed with a left action of G. If $f : E \to S$ is a right S-torsor under G, denote by X_E the S-scheme obtained from X by twisting by means of E and the action of G on X. Let $p : X \to S$ and $q : X_E \to S$ be the canonical projections. Under these conditions, for every A_S-module M and every integer i, the A_S-module $R^i q_*(q^*M)$ is canonically isomorphic to $R^i p_*(p^*M)$.

Proof.

$$\begin{array}{ccc} E \times_S X & \xrightarrow{\varphi} & X_E \\ {\scriptstyle \mathrm{pr}_1}\downarrow & & \downarrow{\scriptstyle q} \\ E & \xrightarrow[f]{} & S \end{array} \qquad \begin{array}{ccc} E \times_S X & \xrightarrow{\mathrm{pr}_2} & X \\ {\scriptstyle \mathrm{pr}_1}\downarrow & & \downarrow{\scriptstyle p} \\ E & \xrightarrow[f]{} & S. \end{array}$$

It is known that diagram (D_1), where φ denotes the canonical passage-to-the-quotient map, is cartesian. Since f is smooth, the smooth base-change theorem gives an isomorphism

$$u : f^* R^i q_*(q^* M) \xrightarrow{\sim} R^i(\mathrm{pr}_1)_*(\varphi^* q^* M).$$

Similarly, the cartesian diagram (D_2) gives an isomorphism

$$v : f^* R^i p_*(p^* M) \xrightarrow{\sim} R^i(\mathrm{pr}_1)_*((\mathrm{pr}_2)^* p^* M).$$

But $p \circ \mathrm{pr}_2 = q \circ \varphi$, so after the evident identification of $\varphi^* \circ q^*$ with $(\mathrm{pr}_2)^* \circ p^*$ one obtains an isomorphism

$$v^{-1} \circ u : f^* R^i q_*(q^* M) \xrightarrow{\sim} f^* R^i p_*(p^* M).$$

Since the geometric fibres of f are non-empty and connected, it follows from (SGA 4 XII 6.5 (i)) that the adjunction morphism

$$\mathrm{adj} : \mathrm{id} \to f_* f^*$$

is an isomorphism, and therefore

$$(\mathrm{adj})^{-1} \circ f_*(v^{-1} \circ u) \circ (\mathrm{adj})$$

is the desired isomorphism.

Proposition 6.2. (Mme Raynaud [5].) Let S be a scheme and let $p : G \to S$ be a reductive S-group scheme (SGA 3 XIX). For every locally constant constructible A_S-module M and every integer i, the A_S-module $R^i p_*(p^* M)$ is locally constant and constructible. Moreover, for every morphism $u : S' \to S$ defining a cartesian diagram

$$\begin{array}{ccc} G' & \xrightarrow{u'} & G \\ {\scriptstyle p'}\downarrow & & \downarrow{\scriptstyle p} \\ S' & \xrightarrow[u]{} & S, \end{array}$$

the base-change morphism

$$u^* R^i p_*(p^* M) \to R^i p'_*(p \circ u')^*(M)$$

is an isomorphism.

Proof. The two assertions of the statement are local for the étale topology of S. By (SGA 3 XII 2.3), we may therefore suppose that G is split. Let B be a Borel subgroup of G of the type indicated in (SGA 3 XXII 5.1.1), so that the quotient G/B exists by (SGA 3 XXII 5.8.5), and let $q : G \to G/B$ and $r : G/B \to S$ be the canonical morphisms. Since r is proper and smooth, it satisfies the proper base-change theorem and the functors $R^i r_*$ send locally constant constructible abelian sheaves to sheaves of the same type (SGA 4 XVI 2.2). Moreover, by (SGA 4 XXII 5.5.1), the

S-scheme B is isomorphic to a finite product of vector bundles and punctured vector bundles, and consequently it follows immediately from (1.1) and (1.2) that, if $t : B \to S$ denotes the canonical morphism, the sheaves $R^i t_*(t^*M)$, with M a locally constant constructible A_S-module, are locally constant constructible and stable under base change. Now let M be a locally constant constructible A_S-module. The preceding considerations and (6.1) imply that the sheaves $R^i q_*(p^*M)$ are locally constant constructible; using the Leray spectral sequence

$$R^i r_*(R^j q_*)(p^*M) \Rightarrow R^{i+j} p_*(p^*M),$$

one deduces the same for the sheaves $R^i p_*(p^*M)$. Finally, by (6.1), the sheaves $R^i q_*(p^*M)$ are stable under base change; using the proper base-change theorem for r, it follows that the sheaves $R^i p_*(p^*M)$ are also stable under base change.

Remark 6.3. Since every reductive S-group is locally, for the étale topology, an inverse image by the canonical morphism $S \to \mathrm{Spec}(\mathbb{Z})$ of a reductive $\mathrm{Spec}(\mathbb{Z})$-scheme (SGA 3 XXIII 5.7 and XXV 1.3), (6.2) shows that the computation of the cohomology, with coefficients of torsion prime to the characteristic, of reductive group schemes over an algebraically closed field reduces to the transcendental problem of computing the cohomology of reductive group schemes of the same type over the field of complex numbers; this is known by the methods of algebraic topology, in view of the comparison theorem (SGA 4 XI 4.4).

Corollary 6.4. Let S be a scheme and let $p : G \to S$ be an S-group scheme which is an extension of a finite étale S-group scheme F by a reductive S-group scheme H. Then the conclusions of (6.2) are valid for every locally constant constructible A_S-module M.

Proof. After the base change $F \to S$, we may suppose that F is of the form Γ_S, where Γ is an ordinary finite group. Then there is an isomorphism of S-schemes

$$G \simeq \coprod_{\gamma \in \Gamma} H,$$

and the conclusion follows from (6.2).

Corollary 6.5. Let S be a scheme, G a reductive S-group scheme, and H a reductive sub-S-group scheme of G, such that the quotient sheaf of G by H for the faithfully flat quasi-compact topology is representable. Then, if

$$p : G/H \to S$$

is the canonical morphism, the conclusions of (6.2) are valid for every locally constant constructible A_S-module M.

Proof. Let $f : G \to G/H$ be the canonical morphism; it is smooth, hence of descent for étale sheaves (SGA 4 VIII 9.1). For every integer $r \geq 0$, put

$$G_r = G \times_{G/H} G \times_{G/H} \cdots \times_{G/H} G \quad (r+1 \text{ times}),$$

which, by SGA 3 V 1.5, is canonically identified with

$$G \times_S H \times_S \cdots \times_S H,$$

where H occurs r times, and let $f_r : G_r \to G/H$ and $g_r : G_r \to S$ be the canonical morphisms, so that in particular $f_0 = f$. Finally, for every integer $q \geq 0$, let $H^q(M)$ denote the complex

$$R^q(g_0)_*(f_0^*M) \to R^q(g_1)_*(f_1^*M) \rightrightarrows \cdots \to R^q(g_r)_*(f_r^*M) \cdots .$$

By (SGA), one has a spectral sequence of descent, or Čech spectral sequence,

$$E(M) : E_2^{pq} = H^p(H^q(M)) \Rightarrow E^n = R^n p_*(M).$$

Since the schemes G_r are reductive group schemes, it follows from 6.2 that the terms E_2^{pq} are locally constant constructible and compatible with every base change. It follows at once that the same is true for the E^n.

7. Complete Intersections

In this paragraph a separably closed field k is given. If ℓ is a prime number $\neq \mathrm{char}(k)$, we denote, for every proper k-scheme X and every integer $i \geq 0$, by

$$b_\ell^i(X) \quad \text{or} \quad b^i(X)$$

when no confusion is possible, the i-th Betti number of X for coefficients $\mathbb{Z}_\ell$. If X is projective over k, a hyperplane section of X means the zero locus of a section transverse to the zero section of a vector bundle $V(\check{\mathcal{L}})$, with $\mathcal{L}$ an ample invertible $\mathcal{O}_X$-module.

Theorem 7.1. (Lefschetz theorem.) Let X be a smooth, connected, projective k-scheme of dimension n, let Y be a subscheme of X which is the intersection of d hyperplane sections of X, and let L be a locally constant constructible A_X-module. Then:

(i) The inverse-image homomorphism

$$H^i(X, L) \to H^i(Y, L|Y)$$

is an isomorphism for $i \leq n - d - 1$ and a monomorphism for $i = n - d$.

(ii) Suppose Y is smooth over k, of dimension $n - d$. Then the Gysin homomorphism

$$H^i(Y, (L|Y) \otimes \mu_Y^{\otimes -d}) \to H^{i+2d}(X, L)$$

is an isomorphism for $i \geq n - d + 1$ and an epimorphism for $i = n - d$.

Proof. It is well known that the complement of a hyperplane section is an affine open; consequently $U = X - Y$ is a union of d affine opens. Assertion (i) then follows immediately from the exact cohomology sequence

$$\cdots \to H_!^i(U, L|U) \to H^i(X, L) \to H^i(Y, L|Y) \xrightarrow{\partial} H_!^{i+1}(U, L|U) \to \cdots$$

and from the following lemma.

Lemma 7.1.1. Let U be a k-scheme of finite type of dimension n, which is a union of d affine open subsets, and let F be an A_U-module. Then:

a) if F is constructible,

$$H^i(U, F) = 0 \qquad \text{for } i \geq n + d;$$

b) if F is locally constant and U is smooth over k,

$$H^i_c(U, F) = 0 \qquad \text{for } i \leq n - d.$$

For $d = 1$, assertion a) is just (SGA 4 XIV 3.2). In the general case, writing $\mathfrak{U}$ for a covering of U by d affine open subsets, one deduces a) from the Čech spectral sequence

$$H^p(\mathfrak{U}, \mathcal{H}^q(F)) \Rightarrow H^{p+q}(U, F).$$

We prove b). Since the functors $H^i_c(U, \cdot)$ commute with filtered inductive limits (SGA 4 VII 3.3), one may suppose F constructible; the assertion then follows from a), by Poincaré duality (SGA 4 XVIII).

Finally, in view of the definition of the Gysin morphism through the canonical isomorphism

$$H^{i-2d}(Y, (L|Y) \otimes \mu_Y^{\otimes -d}) \simeq H^i_Y(X, L), \tag{7.1.2}$$

assertion (ii) follows from 7.1.1 a) and from the exact cohomology sequence associated with an open subset and its complement

$$\cdots \to H^{i-1}(U, L|U) \xrightarrow{\partial} H^i_Y(X, L) \to H^i(X, L) \to H^i(U, L|U) \to \cdots .$$

Remark 7.1.3. In fact, it follows from excision that the canonical isomorphism (7.1.2) generalizes to the case where the smoothness hypothesis on X, and the hypothesis that L is constructible locally constant, are satisfied only in a neighbourhood of Y; hence 7.1 (ii) generalizes in this setting.

For substantially more general formulations, see (SGA 2 XIV 4.6), which, however, is proved only by means of resolution of singularities, and hence provisionally in characteristic 0.

Corollary 7.2. Let X be a smooth connected projective k-scheme of dimension n, let Y be a subscheme of X which is the intersection of d hyperplane sections of X, and let L be a constructible twisted constant $\mathbb{Z}_\ell$-sheaf ($\ell \neq \mathrm{car}(k)$). Then:

(i) the inverse-image homomorphism

$$\alpha_i : H^i(X, L) \to H^i(Y, L|Y)$$

is an isomorphism for $i \leq n - d - 1$, and a monomorphism for $i = n - d$. If moreover L is constructible locally free, the cokernel of α_{n-d} is torsion-free;

(ii) suppose that Y is smooth over k, of dimension $n - d$. Then the Gysin homomorphism

$$\beta_i : H^i(Y, (L|Y)(-d)) \to H^{i+2d}(X, L)$$

is an isomorphism for $i \geq n - d + 1$ and an epimorphism for $i = n - d$. If moreover L is constructible locally free, the epimorphism β_{n-d} is split and its kernel is torsion-free.

Proof. We prove (i), assertion (ii) following from it by Poincaré duality. In the general case, a simple passage to the limit starting from 7.1 (i) gives the conclusion. When L is a locally free $\mathbb{Z}_\ell$-sheaf, apply the following lemma to the inverse-image morphism

$$R\Gamma(X, L) \to R\Gamma(Y, L|Y)$$

in $D(\mathbb{Z}_\ell)$; hypothesis (iii) is satisfied by 7.1 (i).

Lemma 7.2.1. Let V be a discrete valuation ring, let k_V be its residue field, and let $u : K \to L$ be a morphism in $D(V)$. Suppose that K and L have cohomology of finite type, and denote by M the mapping-cylinder of u. Then for every $m \in \mathbb{Z}$ the following conditions are equivalent:

(i) $H^p(M) = 0$ for $p \leq m-1$, and $H^m(M)$ is torsion-free;

(ii) for every V-module N, the morphism

$$H^p(u \otimes^L \mathrm{id}_N) : H^p(K \otimes^L N) \to H^p(L \otimes^L N)$$

is an isomorphism for $p \leq m-1$ and a monomorphism for $p = m$;

(ii bis) for every V-module N, one has

$$H^p(M \otimes^L N) = 0 \qquad (p \leq m-1);$$

(iii) the morphism

$$H^p(u \otimes^L \mathrm{id}) : H^p(K \otimes^L k_V) \to H^p(L \otimes^L k_V)$$

is an isomorphism for $p \leq m-1$ and a monomorphism for $p = m$;

(iii bis) one has

$$H^p(M \otimes^L k_V) = 0 \qquad (p \leq m-1).$$

Moreover these equivalent conditions imply:

(i bis) the morphism

$$H^p(u) : H^p(K) \to H^p(L)$$

is an isomorphism for $p \leq m-1$, and a monomorphism with free cokernel for $p = m$.

Proof. The following diagram of implications is evident:

$$\begin{array}{ccc} \text{(ii)} & \Leftrightarrow & \text{(ii bis)} \\ \Downarrow & & \\ \text{(iii)} & \Leftrightarrow & \text{(iii bis)} \end{array} \qquad \text{(i)} \Rightarrow \text{(i bis)}.$$

We shall prove separately that (i)⇒(ii bis) and that (iii bis)⇒(i), which will suffice. The implication (i)⇒(ii bis) is immediate from the Künneth exact sequence

$$0 \to H^p(M) \otimes_V N \to H^p(M \otimes^L N) \to \mathrm{Tor}_1^V(H^{p+1}(M), N) \to 0.$$

The same exact sequence, for $N = k_V$, shows that if (iii bis) holds, then

$$H^p(M) \otimes k_V = 0 \quad (p \leq m-1), \qquad \mathrm{Tor}_1^V(H^m(M), k_V) = 0.$$

One deduces (i) by Nakayama's lemma and the local criterion of flatness (EGA 0_{III} 10.1.3).

Under the preceding hypotheses, one sees that knowledge of the cohomology groups of X with coefficients in $\mathbb{Q}_\ell$ implies knowledge of those of Y, except in dimension $n-1$. The calculation of that remaining group is immediately reduced, under these conditions, to the calculation of the Euler-Poincaré characteristic of Y. This is the calculation to which we now turn, in a slightly more general setting.

Proposition 7.3. Let X be a proper smooth connected k-scheme of dimension n, let E be a locally free $\mathcal{O}_X$-module of constant rank r, and let Y be the zero-locus of a section of $V(\check{E})$ transverse to the zero-section. Let $p : X \to k$ be the canonical morphism and p_* the corresponding Gysin morphism. Then

$$\mathrm{EP}(Y) = p_*(c(\check{\Omega}^1_X)c(E)^{-1}c_r(E))$$

in $H^0(k, \mathbb{Q}_\ell) = \mathbb{Q}_\ell$.

Proof. By (EGA IV 17.13.2), Y is smooth and purely of dimension $n-r$. If $i : Y \to X$ denotes the canonical immersion, the conormal sheaf of i is the inverse image by i of the conormal sheaf $\check{E}$ to the zero-section of $V(\check{E})$. Thus one has an exact sequence

$$0 \to i^*(\check{E}) \to i^*(\Omega^1_X) \to \Omega^1_Y \to 0, \tag{7.3.1}$$

whence immediately

$$c(\check{\Omega}^1_Y) = i^*(c(\check{\Omega}^1_X)c(E)^{-1}). \tag{7.3.2}$$

By (3.10) we therefore get

$$\mathrm{EP}(Y) = p_*i_*i^*(c(\check{\Omega}^1_X)c(E)^{-1}),$$

or, using the projection formula for i,

$$\mathrm{EP}(Y) = p_*(c(\check{\Omega}^1_X)c(E)^{-1}i_*(1_Y)).$$

The stated formula follows immediately from (4.7).

Corollary 7.4. Let X be a proper smooth connected k-scheme of dimension n, and let Y be a smooth closed subscheme of dimension $n-1$ of X, hence defined by a section of an invertible $\mathcal{O}_X$-module L. Let p be the canonical morphism from X to k and p_* the corresponding Gysin morphism. Then

$$\mathrm{EP}(X) - \mathrm{EP}(Y) = p_*(c(\check{\Omega}^1_X)c(L)^{-1}) \tag{7.4.1}$$

in $H^0(k, \mathbb{Q}_\ell) = \mathbb{Q}_\ell$. Moreover,

$$b^{n-1}(Y) = 2b^{n-1}(X) - b^n(X) + (-1)^n p_*(c(\check{\Omega}^1_X)c(L)^{-1}). \tag{7.4.2}$$

Proof. Formula (7.4.1) follows from 7.3 and 4.2, taking into account the evident identity

$$1 - c(L)^{-1}c_1(L) = c(L)^{-1}.$$

Using (7.2), one sees that

$$b^{n-1}(Y) = b^{n-1}(X) - b^n(X) + b^{n+1}(X) + (-1)^n(\mathrm{EP}(X) - \mathrm{EP}(Y)).$$

But $b^{n-1}(X) = b^{n+1}(X)$ by Poincaré duality, and (7.4.2) follows.

Corollary 7.5. Let X be a smooth connected subscheme of dimension n of $\mathbb{P}^{n+r}_k$, a global complete intersection of r divisors $X_1, X_2, \ldots, X_r$ of $\mathbb{P}^{n+r}_k$. For each $i \in \{1, \ldots, r\}$, let d_i be the degree of X_i. Then:

(i) the cohomology groups $H^p(X, \mathbb{Z}_\ell)$ are free $\mathbb{Z}_\ell$-modules of finite type;

(ii) if p is an integer $\leq 2n$ and $\neq n$, then

$$H^p(X, \mathbb{Z}_\ell) = \begin{cases} 0, & \text{if } p \text{ is odd,} \\ \mathbb{Z}_\ell, & \text{if } p \text{ is even;} \end{cases}$$

(iii) the Euler-Poincaré characteristic of X is given by

$$\mathrm{EP}(X) = d_1 \cdots d_r \sum_{\substack{0 \leq i \leq n \\ j_1 + \cdots + j_r = n-i}} (-1)^{n-i} \binom{n+r+1}{i} d_1^{j_1} \cdots d_r^{j_r}.$$

Proof. Assertion (i) follows immediately from (7.2), and so does (ii), in view of the cohomology of projective spaces (no. 2). We prove (iii). Let P be the ambient projective space, let $p : P \to k$ be the canonical projection, let p_* be the corresponding Gysin morphism, and let ξ be the class of $\mathcal{O}_P(1)$. For every $i \in \{1, \ldots, r\}$, the scheme X_i is defined by a section of an invertible $\mathcal{O}_P$-module L_i, so that X is the zero-locus of a section of $V(\check{L}_1 \oplus \cdots \oplus \check{L}_r)$ transverse to the zero-section. On the other hand, one has an exact sequence

$$0 \to \Omega^1_P \otimes \mathcal{O}_P(1) \to \mathcal{O}_P^{n+r+1} \to \mathcal{O}_P(1) \to 0,$$

hence

$$c(\check{\Omega}^1_P) = (1+\xi)^{n+r+1}.$$

Formula (7.3) gives

$$\begin{aligned} \mathrm{EP}(X) &= p_*(c(\check{\Omega}^1_P) c(\check{L}_1 \oplus \cdots \oplus \check{L}_r)^{-1} c_1(\check{L}_1) \cdots c_1(\check{L}_r)) \\ &= p_*(d_1 \cdots d_r \, \xi^r (1+\xi)^{n+r+1} (1+d_1\xi)^{-1} \cdots (1+d_r\xi)^{-1}). \end{aligned}$$

Using the fact that $p_*(\xi^{n+r}) = 1$ (2.2.2 c)), the formula of the statement follows without difficulty.

Remark 7.6. One may also obtain the expression for the Euler-Poincaré characteristic by using (4.11) and by transcribing Hirzebruch's calculations ([3], pp. 160–161), which use the Riemann-Roch theorem. For a more complete calculation and the determination of the Hodge cohomology of complete intersections, the reader is referred to (SGA 7 XI).

7.7

By analogy with what happens in the transcendental case, where for constant coefficients one has another well-known theorem of Lefschetz ([4]), one is led to conjecture the following statement. If X is a smooth connected projective k-scheme of dimension n, and if ξ is the class in $H^2(X, \mathbb{Z}_\ell(1))$ of a very ample invertible $\mathcal{O}_X$-module, then for every twisted constant $\mathbb{Q}_\ell$-sheaf L and every integer $p \leq n$, multiplication by ξ^{n-p}:

$$H^p(X, L) \to H^{2n-p}(X, L(n-p))$$

is an isomorphism. As Deligne observed, the statements (7.7) are false without an additional hypothesis on L. However, Deligne proved them in *La conjecture de Weil II* when, in addition, L is pure.

This conjectural statement has the following consequences, likewise not proved in car $\neq 0$.

Let X be a smooth connected projective k-scheme of dimension n, let Y be a smooth hyperplane section of X, and let L be a twisted constant $\mathbb{Q}_\ell$-sheaf on X.

(i) The inverse-image morphism
$$H^p(X, L) \to H^p(Y, L|Y)$$
is an epimorphism for $p \geq n$.

(ii) The Gysin morphism
$$H^p(Y, (L|Y)(-1)) \to H^{p+2}(X, L)$$
is a monomorphism for $p \leq n-2$.

Proof. Let $j : X \hookrightarrow \mathbb{P}^r$ be a closed immersion and let ξ_X (resp. ξ_Y) be the class in $H^2(X, \mathbb{Q}_\ell(1))$ (resp. $H^2(Y, \mathbb{Q}_\ell(1))$) of $\mathcal{O}_X(1)$ (resp. $\mathcal{O}_Y(1)$). Let $\alpha : Y \hookrightarrow X$ denote the canonical injection. For $q \leq n-1$, the diagram
$$\begin{array}{ccc} H^q(X, L) & \xrightarrow{\alpha^*} & H^q(Y, L|Y) \\ \cup \xi_X^{n-1-q} \downarrow & & \downarrow \cup \xi_Y^{n-1-q} \\ H^{2n-2-q}(X, L(n-1-q)) & \xrightarrow{\alpha^*} & H^{2n-2-q}(Y, (L|Y)(n-1-q)) \end{array}$$
is commutative and the right column is conjecturally an isomorphism. Put $p = 2n-2-q$. For $q \leq n-2$, hence $p \geq n$, the top row is an isomorphism by (7.2), giving (i). Assertion (ii) is proved similarly by considering, this time, the following diagram, with $p \leq n-1$:
$$\begin{array}{ccc} H^p(Y, (L|Y)(-1)) & \xrightarrow{\text{Gysin}} & H^{p+2}(X, L) \\ \cup \xi_Y^{n-1-p} \downarrow & & \downarrow \cup \xi_X^{n-1-p} \\ H^{2n-2-p}(Y, (L|Y)(n-2-p)) & \xrightarrow{\text{Gysin}} & H^{2n-p}(X, L(n-1-p)). \end{array}$$
In this diagram, the bottom row is an isomorphism for $2n-2-p \geq n$, i.e. for $p \leq n-2$ (7.2 (ii)).

For a discussion of these conjectures and their consequences, the reader is referred to Kleiman's exposé, *Algebraic cycles and the Weil conjectures*, in *Dix exposés sur la cohomologie des schémas.*

8. Blown-up varieties

In this section we give a cohomological variant of the calculations, for the group K and for the "group of cycle classes" of a blown-up scheme, given in SGA 6 VII 3.7 and 4.8. The hypotheses and notations are those of the beginning of paragraph 4 (4.1 to 4.3). Under these conditions, the "fundamental class" morphism
$$\gamma : j_*(\mu_{Y'}^{\otimes -1})[-2] \to A_{X'}$$
gives, after applying the functor Rf_*, a morphism
$$Rf_*(\gamma) : i_* Rg_*(\mu_{Y'}^{\otimes -1})[-2] \to Rf_*(A_{X'}).$$

Theorem 8.1. The morphism in $D^+(X, A)$
$$A_X \oplus i_* Rg_*(\mu_{Y'}^{\otimes -1})[-2] \to Rf_*(A_{X'}) \oplus i_*(\mu_Y^{\otimes -d})[-2d] \tag{8.1.1}$$

defined by the matrix

$$\begin{pmatrix} \mathrm{adj} & Rf_*(\gamma) \\ 0 & i_*(\mathrm{trace}) \end{pmatrix}$$

is an isomorphism.

Proof. By conservativity of the system of fibre functors, it is enough to verify the assertion above each point x of X. It is evident above $U = X - Y$. For $x \in Y$, proper base change reduces us to proving the following lemma, with $r = d - 1$.

Lemma 8.2. Let k be a separably closed field, let $r \geq 1$ be an integer, and let $P = \mathbb{P}^r_k$. Then:

a) the canonical map $A \to H^0(P, A)$ is a bijection;

b) $H^1(P, A) = H^{2r-1}(P, A) = 0$;

c) for $0 \leq p \leq 2r - 2$, multiplication by $\xi = c_1(\mathcal{O}_P(1)) \in H^2(P, \mu)$

$$H^p(P, \mu_P^{\otimes -1}) \to H^{p+2}(P, A)$$

is an isomorphism;

d) the trace morphism

$$H^{2r}(P, \mu_P^{\otimes -1}) \to H^0(k, \mu_k^{\otimes -(r+1)})$$

is a bijection.

The lemma is an immediate consequence of 2.2.2.

For the statement of the following corollary, we agree that, for every X-scheme $h : T \to X$, every closed subset Z of T, and every complex M of A_X-modules, we write

$$H^*(T, M) = H^*(T, h^*(M)), \qquad H^*_Z(T, M) = H^*_Z(T, h^*(M)).$$

Corollary 8.3. For every complex M of A_X-modules and every $p \in \mathbb{Z}$, the maps

$$H^p(X, M) \oplus H^{p-2}(Y', M \otimes \mu^{\otimes -1}) \to H^p(X', M) \oplus H^{p-2d}(Y, M \otimes \mu^{\otimes -d}) \tag{8.3.1}$$

and

$$H^p_Y(X, M) \oplus H^{p-2}(Y', M \otimes \mu^{\otimes -1}) \to H^p_{Y'}(X', M) \oplus H^{p-2d}(Y, M \otimes \mu^{\otimes -d}) \tag{8.3.2}$$

defined by the matrix

$$\begin{pmatrix} f^* & j_* \\ 0 & g_* \end{pmatrix}$$

are bijections.

Proof. Temporarily denote by u the morphism (8.1.1). By the projection formula, the arrows (8.3.1) and (8.3.2) are those induced on the p-th cohomology objects by the morphisms $R\Gamma(X, u \otimes \mathrm{id}_M)$ and $R\Gamma_Y(X, u \otimes \mathrm{id}_M)$ respectively. The assertion follows.

8.4

We now make explicit the inverse isomorphism of (8.3.2), and for this we need a few lemmas.

Lemma 8.4.1. Let S be a scheme, let E be a locally free $\mathcal{O}_S$-module of constant rank d, and let $p : P = \mathbb{P}_S(E) \to S$ be the associated projective bundle. Let F be the $\mathcal{O}_P$-module defined by the canonical exact sequence

$$0 \to F \to p^*(E) \to \mathcal{O}_P(1) \to 0.$$

Then

$$p_*(c_{d-1}(\check{F})) = 1.$$

Proof. Let c_i denote the Chern classes of E, and put $\xi = c_1(\mathcal{O}_P(1))$. From

$$p^*(c(E)) = c(F)(1 + \xi)$$

it follows that

$$c(F) = p^*(c(E))(1 + \xi)^{-1},$$

hence

$$c_{d-1}(F) = \sum_{0 \le i \le d-1} (-1)^{d-1-i} c_i \, \xi^{d-1-i}. \tag{8.4.2}$$

Now p_* lowers degrees by $2d - 2$, and $p_*(\xi^{d-1}) = 1$ (2.2.2). Applying p_* to both sides of (8.4.2) and using the projection formula gives the lemma.

Lemma 8.4.3. Let F denote the locally free $\mathcal{O}_{Y'}$-module defined by the canonical exact sequence

$$0 \to F \to g^*(N) \to \mathcal{O}_{Y'}(1) \to 0.$$

Let M be an A_X-module which is locally constant constructible in a neighbourhood of Y, and let $p \ge 0$ be an integer. For every $y \in H^p(Y, M)$ one has

$$f^*(i_*(y)) = j_*(g^*(y) c_{d-1}(\check{F}))$$

in $H^{p+2d}_{Y'}(X', M \otimes \mu^{\otimes d})$.

Proof. Put

$$z = f^*(i_*(y)) - j_*(g^*(y) c_{d-1}(\check{F})).$$

Then

$$j^*(z) = g^* i^* i_*(y) - j^* j_*(g^*(y) c_{d-1}(\check{F})),$$

so, by (4.1) and the linearity lemma of (SGA 4 XVIII),

$$j^*(z) = g^*(y)(c_d(g^*\check{N}) - c_{d-1}(\check{F}) c_1(\mathcal{O}_{Y'}(-1))) = 0. \tag{8.4.4}$$

Writing $U = X - Y$ and $U' = X' - Y'$, one has an evident exact commutative diagram

$$\begin{array}{ccccc} H^{p+2d-1}(U') & \xrightarrow{\partial} & H^{p+2d}_{Y'}(X') & \xrightarrow{j^*} & H^{p+2d}(Y') \\ \uparrow \wr & & \uparrow f^* & & \uparrow g^* \\ H^{p+2d-1}(U) & \xrightarrow{\partial} & H^{p+2d}_{Y}(X) & \xrightarrow{i^*} & H^{p+2d}(Y), \end{array} \tag{8.4.5}$$

with evident simplifications of notation. Considering (8.4.5) and (8.4.4), one sees that z is of the form

$$z = f^*(t),$$

with $t \in H_Y^{p+2d}(X, M \otimes \mu^{\otimes d})$. By (4.2), $t = f_*(z)$, so it is enough to see that $f_*(z) = 0$. But

$$f_*(z) = f_* f^* i_*(y) - f_* j_*(g^*(y) c_{d-1}(\check{F})),$$

and using (4.2) gives

$$f_*(z) = i_*(y) - i_* g_*(g^*(y) c_{d-1}(\check{F})).$$

The conclusion follows from the projection formula for g and from (8.4.2).

Proposition 8.5. Let M be an A_X-module which is locally constant constructible in a neighbourhood of Y.

a) Let

$$\gamma : H^*_{Y'}(X', M \otimes \mu^{\otimes d}) \to H^*(Y', M \otimes \mu^{\otimes (d-1)})(-2)$$

be the unique map defined by the relation

$$f^* \circ f_* = j_* \circ \gamma + \mathrm{id}\,. \tag{8.5.1}$$

Then

$$g_* \circ \gamma = 0, \tag{8.5.2}$$

and the inverse matrix of (8.3.2) is

$$\begin{pmatrix} f_* & -i_* \\ -\gamma & g^*(\cdot) c_{d-1}(\check{F}) \end{pmatrix}. \tag{8.5.3}$$

b) For every integer $p \geq 0$, the sequence

$$0 \to H^{p-2d}(Y, M(-d)) \xrightarrow{\lambda} H^{p-2}(Y', M(-1)) \oplus H^p(X, M) \xrightarrow{\mu} H^p(X', M) \to 0,$$

where

$$\lambda(x) = (g^*(x) c_{d-1}(\check{F}), -i_*(x)), \qquad \mu(x, y) = j_*(x) + f^*(y),$$

is exact. Moreover, the map λ has the left inverse

$$\lambda'(x, y) = g_*(x).$$

Proof. We prove a). In view of 4.2 ($f_* f^* = \mathrm{id}$), in order to see that

$$\begin{pmatrix} f_* & -i_* \\ -\gamma & g^*(\cdot) c_{d-1}(\check{F}) \end{pmatrix} \circ \begin{pmatrix} f^* & j_* \\ 0 & g_* \end{pmatrix} = \mathrm{id},$$

it is enough to prove

$$\gamma j_* + \mathrm{id} = g^*(g_*(\cdot) c_{d-1}(\check{F})), \tag{8.5.4}$$

and

$$\gamma f^* = 0. \tag{8.5.5}$$

From (8.5.1) one deduces

$$f^*f_*f^* = j_*\gamma f^* + f^*,$$

and hence, by (4.2), $j_*\gamma f^* = 0$; this gives (8.5.5), since j_* is an isomorphism. We prove (8.5.4). Again (8.5.1) gives

$$f^*f_*j_* = j_*\gamma j_* + j_*,$$

so, since $f_*j_* = i_*g_*$ and using (8.4.3),

$$j_*g^*(g_*(\cdot)c_{d-1}(\check{F})) = j_*\gamma j_* + j_*.$$

Multiplying on the left by the inverse of j_* gives (8.5.4). Finally, (8.5.2) is obtained by writing that the product of the two matrices in the other order is the identity.

We prove b). From 8.4.3 and 8.4.1 respectively one gets $\mu \circ \lambda = 0$ and $\lambda' \circ \lambda = \mathrm{id}$. Moreover, μ is surjective by (8.3). It remains to prove that $\mathrm{Ker}(\mu) \subset \mathrm{Im}(\lambda)$. But $\mu \circ (\lambda \circ \lambda') = 0$ and $\lambda' \circ (\lambda \circ \lambda') = \mathrm{id}$, so $\mu(x) = 0$ implies

$$(\mu \oplus \lambda')(\lambda \circ \lambda'(x)) = (\mu \oplus \lambda')(x),$$

and hence $x = \lambda \circ \lambda'(x)$ by 8.3.

8.6

We shall now try to determine the multiplicative structure of the cohomology of X'. For every $p \in \mathbb{Z}$ and every A_X-module M which is locally constant constructible in a neighbourhood of Y, put

$$\nabla^p(X', M) = H^{p-2}(Y', M(-1)) \oplus H^p(X, M).$$

For $p, q \in \mathbb{Z}$ and two such modules M, N, define a composition law

$$\cup : \nabla^p(X', M) \otimes_A \nabla^q(X', N) \to \nabla^{p+q}(X', M \otimes_A N) \tag{8.6.1}$$

by

$$(y'_1, x_1) \cup (y'_2, x_2) = (-y'_1y'_2\xi + y'_1g^*i^*(x_2) + (-1)^{pq}y'_2g^*i^*(x_1),\ x_1x_2). \tag{8.6.2}$$

This composition law is clearly anticommutative, and an easy but tedious calculation shows that it is associative. In particular,

$$\nabla^*(X', A) = \bigoplus_{p \in \mathbb{Z}} \nabla^p(X', A)$$

is also endowed with a structure of graded-commutative A-algebra, in the sense of algebras graded by $\mathbb{Z}$, and

$$\nabla^*(X', M) = \bigoplus_{p \in \mathbb{Z}} \nabla^p(X', M)$$

is endowed with a graded module structure over the graded ring $\nabla^*(X', A)$.

Proposition 8.6.3.

a) For every pair (M, N) of A_X-modules locally constant constructible in a neighbourhood of Y, the diagram

$$\begin{array}{ccc} \nabla^*(X', M) \otimes \nabla^*(X', N) & \xrightarrow{\mu \otimes \mu} & H^*(X', M) \otimes H^*(X', N) \\ \Big\downarrow{\scriptstyle (8.6.1)} & & \Big\downarrow{\scriptstyle \cup} \\ \nabla^*(X', M \otimes N) & \xrightarrow{\mu} & H^*(X', M \otimes N) \end{array}$$

is commutative. In particular, the surjective map

$$\mu_A = \mu : \nabla^*(X', A) \to H^*(X', A)$$

is a ring morphism, and

$$\mu_M = \mu : \nabla^*(X', M) \to H^*(X', M)$$

is a morphism of modules over variable rings.

b) If $\nabla^*(X', A)$ is made to act on $H^*(Y, M(-d))(-2d)$ by the map

$$\nabla^p(X', A) \otimes H^{q-2d}(Y, M(-d)) \to H^{p+q-2d}(Y, M(-d)), \qquad (y', x) \otimes y \mapsto i^*(x)y,$$

then the map λ of 8.5 b) becomes a morphism of $\nabla^*(X', A)$-modules.

Proof. We prove a). With the notation of 8.6.2, one must prove the equality

$$j_*(-y'_1 y'_2 \xi + y'_1 g^* i^*(x_2) + (-1)^{pq} y'_2 g^* i^*(x_1)) + f^*(x_1 x_2)$$
$$= (j_*(y'_1) + f^*(x_1))(j_*(y'_2) + f^*(x_2)).$$

It follows at once from

$$\begin{cases} f^*(x_1) f^*(x_2) = f^*(x_1 x_2), & \text{multiplicativity of } f^*, \\ j_*(-y'_1 y'_2 \xi) = j_*(y'_1) j_*(y'_2), & (4.5), \\ j_*(y' g^* i^*(x)) = j_*(y' j^* f^*(x)) = j_*(y') f^*(x), & \text{projection formula.} \end{cases}$$

We prove b). The equality to be proved,

$$\lambda(i^*(x) \cdot y) = (y', x) \cdot \lambda(y),$$

breaks up into the two following equalities:

$$g^*(i^*(x) \cdot y) c_{d-1}(\check{F}) = -y' g^*(y) c_{d-1}(\check{F}) \xi + y' g^* i^*(-i_*(y)) + g^*(i^* x) g^*(y) c_{d-1}(\check{F}),$$

and

$$-i_*(i^*(x) y) = -x\, i_*(y).$$

The second is just the projection formula for i. The first follows immediately from

$$-\xi\, c_{d-1}(\check{F}) = g^*[c_d(\check{N})] \quad \text{(exact sequence of 8.4.3)}$$

and

$$i^* i_*(y) = y\, c_d(\check{N}) \qquad (4.1).$$

9. Chow ring of a blown-up variety and the self-intersection formula in the Chow ring

In this paragraph we propose to give Mumford's proof of the analogue of 4.1 in the Chow ring. We shall then show how one can deduce from it the "key formula" (8.4.3), and hence determine the structure of the Chow ring of a blown-up variety.

In accordance with the conventions of 3.9, $C^*(X)$ denotes the Chow ring of a quasi-projective smooth scheme X over a field k. The theory of Chern classes used is that of [1]. We shall use the following lemma several times.

Lemma 9.1. Let S be a quasi-projective smooth scheme over a separably closed field k, let E be a locally free $\mathcal{O}_S$-module of constant rank $r+1$, and let $p : P = \mathbb{P}_S(E) \to S$ be the associated projective bundle. Let F be the $\mathcal{O}_P$-module defined by the canonical exact sequence

$$0 \to F \to p^*(E) \to \mathcal{O}_P(1) \to 0, \tag{9.1.0}$$

and put $\xi = c_1(\mathcal{O}_P(1))$. Then:

(i) for every $y \in C^*(S)$,

$$y = p_*(p^*(y)c_r(\check{F})); \tag{9.1.1}$$

(ii) suppose that $E = N \oplus \mathcal{O}_S$, with N a locally free $\mathcal{O}_S$-module of rank r, so that P identifies with the projective completion $\widehat{N}$ of $V(N)$, and let

$$s : S \to \mathbb{P}_S(E)$$

be the section obtained by composing the zero-section of $V(N)$ with the canonical inclusion $V(N) \hookrightarrow \widehat{N}$. Then:

(a) for every $y \in C^*(S)$ one has

$$s_*(y) = p^*(y)c_r(\check{F}) = p^*(y)\left(\sum_{i=0}^{r} p^*(c_i(\check{N}))\xi^{r-i}\right) \quad \text{in } C^*(\widehat{N}), \tag{9.1.2}$$

$$s^*s_*(y) = y\, c_r(\check{N}) \quad \text{in } C^*(S); \tag{9.1.3}$$

(b) for every $z \in C^*(\widehat{N})$,

$$s^*(z) = p_*(z\, c_r(\check{F})) \quad \text{in } C^*(S). \tag{9.1.4}$$

Proof. We prove (9.1.1). By the projection formula for p, it is enough to show that $p_*(c_r(\check{F})) = 1$. For this it suffices to copy the proof of 8.4.1, using the relations ([CH] 4 (17)). The equality of the first and third members of (9.1.2) is just Lemma 3 of [1]. Paraphrasing the proof of (8.4.1), one sees that

$$c_r(\check{F}) = \sum_{i=0}^{r} p^*(c_i(\check{N}))\xi^{r-i}, \tag{9.1.2 bis}$$

which proves (9.1.2). Applying s^* to the two extreme members of (9.1.2), and using $p \circ s = \mathrm{id}$, one sees that (9.1.3) will follow from

$$s^*\left(\sum_{i=0}^{r-1} p^*(c_i(\check{N}))\xi^{r-i}\right) = 0,$$

and a fortiori from

$$s^*(\xi^i) = 0 \qquad (i > 0). \tag{9.1.5}$$

We prove (9.1.5). If $\alpha : V(N) \hookrightarrow \widehat{N}$ denotes the canonical inclusion, then evidently $\alpha^*(\mathcal{O}_P(1)) \simeq \mathcal{O}_{V(N)}$, whence

$$\alpha^*(\xi) = \alpha^*(c_1(\mathcal{O}_P(1))) = c_1(\mathcal{O}_{V(N)}) = 0$$

by functoriality of Chern classes. The assertion follows immediately from the definition of s. We prove (9.1.4). We shall use the equality

$$\xi\, c_r(\check{F}) = c_{r+1}(p^*(\check{N}) \oplus \mathcal{O}'_P) = 0, \tag{9.1.6}$$

which follows at once from the exact sequence (9.1.0). The element z has a unique decomposition

$$z = \sum_{i=0}^{r} p^*(a_i)\xi^i, \qquad a_i \in C^*(S),$$

([CH] 4 Th. 1). It follows from (9.1.5) that $s^*(z) = a_0$. On the other hand, (9.1.6) shows that $z\, c_r(\check{F}) = p^*(a_0)c_r(\check{F})$, and the conclusion follows from (9.1.1).

We now state the self-intersection formula in the Chow ring.

Theorem 9.2 (Mumford). Let k be a separably closed field and let $i : Y \hookrightarrow X$ be a closed immersion, purely of codimension d, of quasi-projective smooth k-schemes. If N denotes the normal sheaf of i, then for every $y \in C^*(Y)$ one has

$$i^* i_*(y) = y\, c_d(\check{N})$$

in $C^*(Y)$.

For the proof we shall need a number of notations and auxiliary schemes. Embed X in $Z = X \times_k \mathbb{P}^1_k$ by the morphism $u : t \mapsto (t, 0)$, so that there is a cartesian diagram

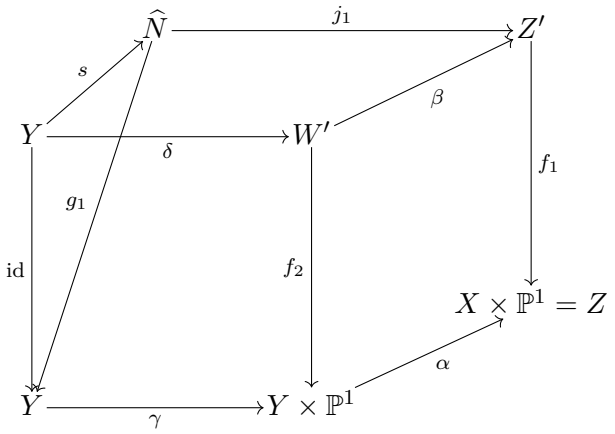
$$\begin{array}{ccc} \widehat{N} & \xrightarrow{j_1} & Z' \\ {\scriptstyle g_1}\downarrow & & \downarrow{\scriptstyle f_1} \\ Y & \xrightarrow[i_1]{} & Z, \end{array}$$

where Z' denotes the blowing-up of Z along Y, and $\widehat{N} = \mathbb{P}_Y(N \oplus \mathcal{O}_Y)$ is the projective completion of the vector bundle $V(N)$. As in the statement of 9.1, let $s : Y \hookrightarrow \widehat{N}$ be the morphism obtained by composing the zero-section of $V(N)$ with the canonical inclusion $V(N) \subset \widehat{N}$.

The inclusion $Y \subset X$ identifies $Y \times \mathbb{P}^1$ with a closed subscheme of $X \times \mathbb{P}^1$. Let W' be the strict transform of $Y \times \mathbb{P}^1$ by f_1, i.e. the subscheme of Z' obtained by blowing up $Y \times \mathbb{P}^1$ along $Y = Y \times 0$. It is clear that $W' \cap \widehat{N}$ identifies with the zero-section of $\widehat{N}$ and that, since Y has codimension 1 in $Y \times \mathbb{P}^1$, the canonical morphism $f_2 : W' \to Y \times \mathbb{P}^1$ is an isomorphism. The remaining notation

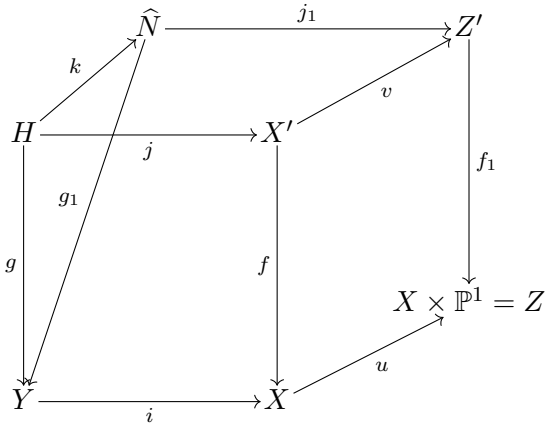
relative to W' is fixed by the canonical diagram (D_1).

(D_1)



Similarly, if X' denotes the closed subscheme of Z' which is the blowing-up of $X = X \times 0$ along Y, it is clear that $\mathbb{P}(N) = X' \cap \widehat{N}$ identifies with the hyperplane at infinity H of $\widehat{N}$. The remaining notation relative to X' is fixed by the canonical diagram (D_2).

(D_2)



We now give, in lemma form, a number of relations useful below. Denote by E the locally free $\mathcal{O}_{\widehat{N}}$-module defined by the canonical exact sequence

$$0 \to E \to g_1^*(N \oplus \mathcal{O}_Y) \to \mathcal{O}_{\widehat{N}}(1) \to 0, \tag{9.3.0}$$

and put

$$\bar{\xi} = c_1(\mathcal{O}_{\widehat{N}}(1)). \tag{9.3.1}$$

Lemma 9.3. With the preceding notation, one has

$$j_1^*(\beta_*(1)) = c_d(\check{E}) \quad \text{in } C^*(\widehat{N}), \tag{9.3.2}$$

$$j_1^*(v_*(1)) = \bar{\xi} \quad \text{in } C^*(\widehat{N}), \tag{9.3.3}$$

$$f_1^* u_*(1) = (j_1)_*(1) + v_*(1) \quad \text{in } C^*(Z'). \tag{9.3.4}$$

Proof. All the k-schemes under consideration are smooth, so it is immediate for dimension reasons that the morphisms j_1 and β (resp. j_1 and v) are transverse. From ([CH] 4 Cor. 1 to Prop. 2) one obtains

$$\begin{cases} j_1^*\beta_*(1) = s_*(1), \\ j_1^* v_*(1) = k_*(1). \end{cases}$$

Equations (9.3.2) and (9.3.3) then come from (9.1.2) and from the normalization of Chern classes ([CH] 4–18), respectively. We prove (9.3.4). Since the cycle X' of Z' is the strict transform of $X \times 0$ by f_1, one has a priori an equality of the form

$$f_1^* u_*(1) = (j_1)_* g_1^*(\mu) + v_*(1), \tag{9.3.5}$$

with $\mu \in \Gamma(Y, \mathbb{N})$; it remains to show that $\mu = 1$. Applying j_1^* to both sides of (9.3.5), one obtains, cf. (D_2),

$$g_1^* i^* u^* u_*(1) = j_1^*(j_1)_* g_1^*(\mu) + j_1^* v_*(1). \tag{9.3.6}$$

A very special case of (9.1.3), or a direct verification, shows that $u^* u_*(1) = 0$. Using (9.3.3), it follows from (9.3.6) that

$$0 = j_1^*(j_1)_* g^*(\mu) + \bar{\xi}. \tag{9.3.7}$$

After restricting to a neighbourhood of a connected component of Y, one may suppose Y connected, so that (9.3.7) takes the form

$$0 = \mu\, j_1^*(j_1)_*(1) + \bar{\xi}, \qquad \mu \in \mathbb{N}. \tag{9.3.7 bis}$$

Since $j_1^*(j_1)_*(1)$ is homogeneous of degree 1, it is of the form

$$j_1^*(j_1)_*(1) = g_1^*(\rho) + \nu\bar{\xi},$$

with $\rho \in C^1(Y)$ and $\nu \in \mathbb{Z}$. Substituting this expression into (9.3.7 bis) gives at once $\rho = 0$ and $\mu\nu = -1$, with $\mu \in \mathbb{N}$; hence $\mu = 1$ and $\nu = -1$, completing the proof of (9.3.4).

The key to the proof of 9.2 lies in the proof of the following lemma, which would be evident if one knew, as in cohomology, that

$$j_1^*(j_1)_*(y) = -y\bar{\xi}$$

for every $y \in C^*(\widehat{N})$.

Lemma 9.4. For every $y \in C^*(\widehat{N})$, one has

$$c_d(\check{E})\, j_1^*(j_1)_*(y) = 0.$$

Proof. The element y has a unique decomposition in $C^*(\widehat{N})$ of the form

$$y = \sum_{0 \le p \le d} g_1^*(a_p)\bar{\xi}^p,$$

or, by (9.3.3),

$$y = \sum_{0 \le p \le d} g_1^*(a_p)\big(j_1^* v_*(1)\big)^p. \tag{9.4.1}$$

Using the projection formula ([CH] 4 I 9) for j_1 and (9.1.6), it follows that

$$c_d(\check{E})\, j_1^*(j_1)_*(y) = c_d(E)\, j_1^*(j_1)_* g_1^*(a_0);$$

in other words, we are reduced to proving 9.4 when y is of the form $g_1^*(a)$, with $a \in C^*(Y)$. Then $j_1^*(j_1)_* g_1^*(a)$ has in turn a unique decomposition in $C^*(\widehat{N})$ of the form

$$j_1^*(j_1)_* g_1^*(a) = \sum_{0 \le p \le d} g_1^*(b_p)\bar{\xi}^p, \tag{9.4.2}$$

and, using (9.1.6) once again, it remains to prove that $g_1^*(b_0)c_d(\check{E}) = 0$. In fact, we shall prove the stronger statement $b_0 = 0$. In view of (9.3.3), we may rewrite (9.4.2) as

$$j_1^*(j_1)_* g_1^*(a) = g_1^*(b_0) + z\, j_1^* v_*(1), \tag{9.4.3}$$

with $z \in C^*(\widehat{N})$. Applying $(j_1)_*$ to both sides of (9.4.3) and using the projection formula for j_1, one gets

$$(j_1)_* g_1^*(b_0) = \big[(j_1)_* g_1^*(a)\big](j_1)_*(1) - v_*(1)(j_1)_*(z). \tag{9.4.4}$$

Substituting in (9.4.4) the expression for $(j_1)_*(1)$ deduced from (9.3.4) gives

$$(j_1)_* g_1^*(b_0) = (j_1)_* g_1^*(a) f_1^* u_*(1) - v_*(1)\big[(j_1)_* g_1^*(a) + (j_1)_*(z)\big]. \tag{9.4.5}$$

Since $X \times 0$ is linearly equivalent to $X \times 1$ in $X \times \mathbb{P}^1$, one has

$$(j_1)_* g_1^*(a) f_1^* u_*(1) = 0. \tag{9.4.6}$$

Comparing with (9.4.5), we get

$$(j_1)_* g_1^*(b_0) = -v_*(1)\big[(j_1)_* g_1^*(a) + (j_1)_*(z)\big]. \tag{9.4.7}$$

Moreover, it is clear that $W' \cap X' = \emptyset$: they could meet at most above Y, where one gives the zero-section and the other the hyperplane at infinity of $\widehat{N}$. Hence $\beta^* v_*(1) = 0$, and from (9.4.7)

$$\beta^*(j_1)_* g_1^*(b_0) = 0. \tag{9.4.8}$$

But, as already observed in the proof of 9.3.2, β and j_1 are transverse; thus (9.4.8) gives

$$0 = \delta_* s^* g_1^*(b_0) = \delta_*(b_0). \tag{9.4.9}$$

Finally, applying $(f_2)_*$ to (9.4.9), one obtains $\gamma_*(b_0) = 0$, whence $b_0 = 0$, since γ_* is injective (γ admits an evident retraction).

9.5

We finally show how the preceding results imply the theorem. Let $p : X \times \mathbb{P}^1_k \to X$ be the first projection, so that $i = p \circ i_1$. If $y \in C^*(Y)$, then evidently

$$i^* i_*(y) = (i_1)^*(\bar{x}), \qquad \bar{x} = p^* i_*(y). \tag{9.5.1}$$

By (9.1.1) it follows that

$$i^* i_*(y) = (g_1)_*\big[g_1^* i_1^*(\bar{x}) c_d(\check{E})\big],$$

hence

$$i^* i_*(y) = (g_1)_*\big[j_1^* f_1^*(\bar{x}) \cdot c_d(\check{E})\big]. \tag{9.5.2}$$

To prove the theorem, by linearity we may suppose that y is the irreducible cycle associated with a subvariety T of Y, so that $\bar{x}$ corresponds to the cycle $T \times \mathbb{P}^1$ of $Z = X \times \mathbb{P}^1$. Let θ denote the strict transform of $T \times \mathbb{P}^1$ by f_1, i.e. the closure of the inverse image of $T \times \mathbb{P}^1$ over $Z \setminus Y$. Then

$$f_1^*(\bar{x}) = \theta + (j_1)_*(w), \qquad w \in C^*(\widehat{N}). \tag{9.5.3}$$

Substituting this expression into (9.5.2), 9.4 gives

$$i^* i_*(y) = (g_1)_*\big[j_1^*(\theta) c_d(\check{E})\big], \tag{9.5.4}$$

and, by (9.1.4),

$$i^* i_*(y) = s^* j_1^*(\theta). \tag{9.5.5}$$

But the reduced scheme underlying θ is the blowing-up of $T \times \mathbb{P}^1$ along $T = (T \times \mathbb{P}^1) \cap Y$; it meets the zero-section of $\widehat{N}$ transversely along the image of T by that zero-section. Hence

$$j_1^*(\theta) = s_*(y),$$

which, together with (9.5.5) and (9.1.3), completes the proof of the theorem.

We now turn to the "key formula" mentioned in the introduction. The adapted notation, recalled for the most part, is that of 4. Observe that it is compatible with the notation introduced in the present paragraph, except that the scheme denoted Y' in 4 is here denoted H (for "hyperplane"). We shall use both notations concurrently.

Proposition 9.6. Let k be a separably closed field and let $i : Y \hookrightarrow X$ be a closed immersion, purely of codimension d, of quasi-projective smooth k-schemes. Let $f : X' \to X$ be the X-scheme obtained by blowing up X along Y, and let

$$\begin{array}{ccc} Y' & \xrightarrow{j} & X' \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle f} \\ Y & \xrightarrow[i]{} & X \end{array}$$

be the cartesian diagram obtained from f and i. If F denotes the locally free $\mathcal{O}_{Y'}$-module defined by the canonical exact sequence

$$0 \to F \to g^*(N) \to \mathcal{O}_{Y'}(1) \to 0, \tag{9.6.1}$$

then

$$f^* i_*(y) = j_*(g^*(y) c_{d-1}(\check{F})) \tag{9.6.2}$$

in $C^*(X')$, for every $y \in C^*(Y)$.

Before proving 9.6, we isolate in a lemma some properties of the diagrams (D_1) and (D_2) which have not yet been established.

Lemma 9.7. One has

$$c_d(\check{E}) = k_*(c_{d-1}(\check{F})) + (g_1)^*(c_d(\check{N})), \tag{9.7 i}$$

$$\beta_* f_2^* \gamma_*(y) = f_1^* \alpha_* \gamma_*(y) \qquad \text{for every } y \in C^*(Y), \tag{9.7 ii}$$

$$f_1^* u_*(t) = (j_1)_*((i \circ g_1)^*(t)) + v_* f^*(t) \qquad \text{for every } t \in C^*(X). \tag{9.7 iii}$$

Proof. We prove (i). Put $\xi = c_1(\mathcal{O}_{Y'}(1)) = k^*(\bar{\xi})$. Paraphrasing the proof of (8.4.1), one obtains

$$c_d(\check{E}) = \sum_{p=0}^{d} g_1^*(c_p(\check{N}))\bar{\xi}^{d-p}, \tag{9.7.1}$$

$$c_{d-1}(\check{F}) = \sum_{q=0}^{d-1} g^*(c_q(\check{N}))\xi^{d-1-q}. \tag{9.7.2}$$

From (9.7.2) one gets

$$k_*[c_{d-1}(\check{F})] = \sum_{q=0}^{d-1} k_* k^*[g_1^*(c_q(\check{N}))\bar{\xi}^{d-1-q}],$$

and hence, by the projection formula for k and the fact that $k_*(1) = \bar{\xi}$,

$$k_*[c_{d-1}(\check{F})] = \sum_{q=0}^{d-1} g_1^*(c_q(\check{N}))\bar{\xi}^{d-q}. \tag{9.7.3}$$

Assertion (i) follows at once by comparing (9.7.1) and (9.7.3). We prove (ii). We may suppose that y is an irreducible cycle of Y, corresponding to a subvariety denoted by the same letter. Then the cycle $\gamma_*(y) = y \times 0$ is rationally equivalent to $y \times 1$, so it is enough to verify the equality of cycles

$$\beta_* f_2^*(y \times 1) = f_1^* \alpha_*(y \times 1). \tag{9.7.4}$$

Since $(y \times 1) \cap (y \times 0) = \emptyset$, f_1 is an isomorphism above an open neighbourhood of $y \times 1$, which gives (9.7.4). We prove (iii). If $p : X \times \mathbb{P}^1 \to X$ is the first projection, then (9.1.2) gives

$$u_*(t) = p^*(t)u_*(1), \tag{9.7.5}$$

and comparing with (9.3.4) yields

$$f_1^* u_*(t) = (p \circ f_1)^*(t)\big[(j_1)_*(1) + v_*(1)\big]. \tag{9.7.6}$$

The projection formulas for j_1 and v then give

$$f_1^* u_*(t) = (j_1)_*\big[(p \circ f_1 \circ j_1)^*(t)\big] + v_*\big[(p \circ f_1 \circ v)^*(t)\big], \tag{9.7.7}$$

which is (iii), since $p \circ f_1 \circ j_1 = i \circ g_1$ and $p \circ f_1 \circ v = f$.

9.8

We now prove 9.6. We shall first prove

$$v_* f^* i_*(y) = v_* j_*(g^*(y) c_{d-1}(\check{F})), \tag{9.8.1}$$

and then prove that v_* is injective. From (9.7)(iii) one gets

$$v_* f^* i_*(y) = f_1^* u_* i_*(y) - (j_1)_*[g_1^* i^* i_*(y)],$$

and therefore, by (9.2),

$$v_* f^* i_*(y) = f_1^*(i_1)_*(y) - (j_1)_*[g_1^*(y\, c_d(\check{N}))]. \tag{9.8.2}$$

On the other hand,

$$v_*j_*(g^*(y)c_{d-1}(\check{F})) = (j_1)_*[k_*k^*g_1^*(y)c_{d-1}(\check{F})],$$

or, by the projection formula for k,

$$v_*j_*(g^*(y)c_{d-1}(\check{F})) = (j_1)_*[g_1^*(y)k_*(c_{d-1}(\check{F}))].$$

Using (9.7)(i), this gives

$$v_*j_*(g^*(y)c_{d-1}(\check{F})) = (j_1)_*[g_1^*(y)c_d(\check{E})] - (j_1)_*[g_1^*(y\,c_d(\check{N}))]. \tag{9.8.3}$$

Comparing (9.8.2) and (9.8.3), one sees that (9.8.1) is equivalent to

$$f_1^*(i_1)_*(y) = (j_1)_*[g_1^*(y)c_d(\check{E})], \tag{9.8.4}$$

i.e. to the equality corresponding to (9.6.2) when X is replaced by $X \times \mathbb{P}^1$. By (9.1.2),

$$(j_1)_*[g_1^*(y)c_d(\check{E})] = (j_1)_*s_*(y) = \beta_*\delta_*(y).$$

But it is immediate (cf. (D_1)) that $\delta_* = f_2^*\gamma_*$, whence:

$$(j_1)_*[g_1^*(y)c_d(\check{E})] = \beta_*f_2^*\gamma_*(y). \tag{9.8.5}$$

Also, evidently,

$$f_1^*(i_1)_*(y) = f_1^*\alpha_*\gamma_*(y), \tag{9.8.6}$$

and (9.8.4) follows by comparing (9.8.5), (9.8.6), and (9.7)(ii).

Lemma 9.8.7. The map v_* is injective.

Proof. Let Z'' be the blowing-up of Z' along W', or equivalently along $\widehat{N} \cup W' = f_1^{-1}(Y \times \mathbb{P}^1)$. The strict transform X'' of X in Z'' is also the strict transform of X' in Z''. The notation is determined by the canonical diagram

$$\begin{array}{ccc} X'' & \xrightarrow{v''} & Z'' \\ {\scriptstyle f'}\big\downarrow\wr & & \big\downarrow{\scriptstyle f_1'} \\ X' & \xrightarrow[v]{} & Z'. \end{array}$$

Since $X' \cap W' = \emptyset$, the morphism f_1' is an isomorphism above an open neighbourhood of X', and in particular f' is an isomorphism. Moreover, since f_1' is transverse to v, one has

$$(f_1')^* \circ v_* = v_*'' \circ (f')^*, \tag{9.8.8}$$

so it is enough to show that v_*'' is injective. But, by the commutativity property of blow-ups (see, for example, Hironaka: *Smoothing of algebraic cycles*, Amer. Journal of Math. (1968), Lemma 4.1), Z'' can also be obtained by first blowing up $X \times \mathbb{P}^1$ along $Y \times \mathbb{P}^1$, yielding a scheme Z_1', and then blowing up Z_1' along the inverse image of Y. Clearly $Z_1' = X' \times \mathbb{P}^1$, and the projection $Z_1' \to X \times \mathbb{P}^1$ is the product $f \times \mathrm{id}_{\mathbb{P}^1}$; hence the evident cartesian diagram

$$\begin{array}{ccccc} H & \xrightarrow{t\mapsto(t,0)} & H \times \mathbb{P}^1 & \xrightarrow{j\times\mathrm{id}} & X' \times \mathbb{P}^1 = Z_1' \\ {\scriptstyle g}\big\downarrow & & \big\downarrow{\scriptstyle g\times\mathrm{id}} & & \big\downarrow{\scriptstyle f\times\mathrm{id}} \\ Y & \xrightarrow{\gamma} & Y \times \mathbb{P}^1 & \xrightarrow{i\times\mathrm{id}} & X \times \mathbb{P}^1 \end{array}$$

The strict transform of $X\times 0$ by $f\times\mathrm{id}$ identifies with $X'\times 0$, which contains $H = H\times 0 = (f\times\mathrm{id})^{-1}(Y)$. If we now blow up Z'_1 along H, then, since H is purely of codimension 1 in X', the strict transform of X' is canonically isomorphic to X' (as was already known); hence the canonical commutative diagram

$$\begin{array}{ccccc} & & X' & \xrightarrow{v''} & Z'' \\ & & \downarrow{\scriptstyle f''} & & \downarrow{\scriptstyle f''_1} \\ H & \longrightarrow & X' & \xrightarrow{v'} & X'\times\mathbb{P}^1 \end{array}$$

$$t \longmapsto (t,0)$$

Recall that we wish to prove that v''_* is injective. Comparing with (D_2), we see that this is equivalent to proving that v_* is injective when, in addition, Y has codimension 1 in X; this is what we now do. But then the identity $(f_1)_*\circ v_* = u_*\circ f_*$ gives the conclusion, since f_* is an isomorphism and u_* is a direct monomorphism (u admits a retraction).

We now state the theorem corresponding to (8.5 b).

Theorem 9.9. For every integer $p\geq 0$, the sequence

$$0\to C^{p-d}(Y)\xrightarrow{\lambda} C^{p-1}(Y')\oplus C^p(X)\xrightarrow{\mu} C^p(X')\to 0$$

in which λ and μ are the maps

$$\lambda : x\mapsto (g^*(x)c_{d-1}(\check{F}), -i_*(x)), \qquad \mu : (x,y)\mapsto j_*(x)+f^*(y)$$

is exact. Moreover, the map λ has the left inverse

$$\lambda' : (x,y)\mapsto g_*(x).$$

Proof. The last assertion is just (9.1.1). Likewise, (9.6.2) says that $\mu\circ\lambda = 0$. We prove that μ is surjective. We shall need

$$f_*f^*(z) = z \qquad (z\in C^*(X)), \tag{9.9.1}$$

which follows immediately from the projection formula for f and the evident fact that $f_*(1)=1$. Let $t\in C^p(X')$. By (9.9.1),

$$f_*(t - f^*f_*(t)) = 0.$$

Since f induces an isomorphism from $U' = X' - Y'$ to $U = X - Y$, the restriction of $t - f^*f_*(t)$ to U' is zero, and hence ([CH] 4 th. 2) there is an equality

$$t - f^*f_*(t) = j_*(a) \qquad \text{with } a\in C^*(Y').$$

We now prove exactness in the middle. Let $a\in C^{p-1}(Y')$ and $b\in C^p(X)$ satisfy

$$j_*(a) + f^*(b) = 0. \tag{9.9.2}$$

Applying f_* to both sides gives

$$f_*j_*(a) + f_*f^*(b) = 0,$$

and in view of (9.9.1),

$$b = -i_* g_*(a). \tag{9.9.3}$$

Putting $x = g_*(a)$, it remains only to prove that

$$a = g^*(x) c_{d-1}(\check{F}). \tag{9.9.4}$$

Put

$$z = a - g^*(x) c_{d-1}(\check{F}) \qquad (x = g_*(a)),$$

and prove $z = 0$. We shall first show that $j_*(z) = 0$ and $g_*(z) = 0$, and then that an element z satisfying these two relations is necessarily zero. By definition,

$$j_*(z) = j_*(a) - j_*(g^*(x) \cdot c_{d-1}(\check{F})),$$

so, by (9.6.2),

$$j_*(z) = j_*(a) - f^* i_*(x).$$

Replacing $i_*(x)$ by $-b$ using (9.9.3), one deduces from (9.9.2) that $j_*(z) = 0$. By the definition of x,

$$g_*(z) = x - g_*(g^*(x) c_{d-1}(\check{F})) = 0$$

by the last assertion of the theorem. It remains to explain why the vanishing of z follows from $j_*(z) = 0$ and $g_*(z) = 0$. Since $Y' = \mathbb{P}_Y(N)$, z has a unique expression

$$z = g^*(a_0) + g^*(a_1)\xi + \cdots + g^*(a_{d-1})\xi^{d-1},$$

where $a_i \in C^{p-1-i}(Y)$. Since $g_*(z) = 0$, the projection formula for g, together with the fact that g_* lowers degrees by $d-1$, gives $a_{d-1} = 0$. On the other hand, by (9.2),

$$z\,\xi = j^* j_*(z) = 0,$$

hence

$$g^*(a_0)\xi + \cdots + g^*(a_{d-1})\xi^{d-1} = 0.$$

Thus all a_i are zero and $z = 0$.

9.10

With the notation of (9.9), the map

$$\omega = \lambda \circ \lambda'$$

is a projector satisfying $\mathrm{Im}(\omega) = \mathrm{Im}(\lambda)$. Therefore μ induces an isomorphism

$$\bar{\mu} : \mathrm{Ker}(\omega) \xrightarrow{\sim} C^p(X').$$

But

$$\mathrm{Ker}(\omega) = \mathrm{Ker}(g_*) \oplus C^p(X) \hookrightarrow C^{p-1}(Y') \oplus C^p(X). \tag{9.10.1}$$

Indeed, an element (x, y) of $C^{p-1}(Y') \oplus C^p(X)$ belongs to $\mathrm{Ker}(\omega)$ if and only if

$$g^* g_*(x) \cdot c_{d-1}(\check{F}) = -i_* g_*(x) = 0,$$

that is, in view of (9.1.1), if and only if $g_*(x) = 0$. On the other hand, the structure of the Chow ring of a projective bundle, and in particular the relations

$$g_*(\xi^i) = 0 \quad \text{for } i < d-1, \qquad g_*(\xi^{d-1}) = 1,$$

show that

$$\mathrm{Ker}(g_*) = g^*C^{p-1}(Y) \oplus g^*C^{p-2}(Y)\xi \oplus \cdots \oplus g^*C^{p-d+1}(Y)\xi^{d-2}.$$

In other words, $\bar{\mu}$ may be interpreted as an isomorphism

$$C^{p-1}(Y) \oplus C^{p-2}(Y) \oplus \cdots \oplus C^{p-d+1}(Y) \oplus C^p(X) \xrightarrow{\sim} C^p(X'), \tag{9.10.2}$$

whose inverse is easy to exhibit.

As Murre pointed out to me, the statement (9.10.2) was proved for $d = 2$ by Samuel in *Relations d'équivalence*, Proceedings of the International Congress, Edinburgh 1958.

Of course, in the framework of étale or ℓ-adic cohomology one has an analogue of (9.10.2), deduced this time from (8.5).

Exposé VIII

GROUPS OF CLASSES OF ABELIAN AND TRIANGULATED CATEGORIES. PERFECT COMPLEXES.

by A. Grothendieck, written up by I. Bucur

In the present exposé, we quickly outline the notions and results which will be indispensable to us in the following exposés, concerning in particular pseudo-coherent and perfect complexes. A more complete exposé on the latter, with more detailed proofs, will appear in the first exposés of the seminar on the Riemann-Roch theorem for schemes, which will follow the present seminar.[22]

1. The case of abelian categories

Let $\mathcal{C}$ be an abelian category and let $\mathcal{D}$ be a full subcategory of $\mathcal{C}$. A function f from $\mathcal{D}$ to an abelian group G is said to be additive if, for every exact sequence in $\mathcal{C}$

$$0 \longrightarrow E' \longrightarrow E \longrightarrow E'' \longrightarrow 0,$$

such that E', E'', and E are objects of $\mathcal{D}$, one has

$$f(E) = f(E') + f(E'').$$

Let f be an additive function from $\mathcal{D}$ to an abelian group G. The following properties are easy consequences of the definition:

$\alpha)$ $f(0) = 0$, $\quad$ $\beta)$ $f(X) = f(Y)$ if X and Y are isomorphic,

$\gamma)$ $f(X \oplus Y) = f(X) + f(Y)$.

$\delta)$ Let $E = (E^i, d^i)$ be a finite complex in $\mathcal{D}$

such that the objects $B^{i+1} = \mathrm{Im}(d^i)$, $Z^i = \mathrm{Ker}(d^i)$ and $H^i(E) = Z^i/B^i$ are in $\mathcal{D}$. Then

$$\sum_i (-1)^i f(E^i) = \sum_i (-1)^i f(H^i(E)).$$

$\varepsilon)$ If $F \in \mathrm{ob}\,\mathcal{D}$ has a finite filtration

$$0 = F_0 \subset F_1 \subset \cdots \subset F_n = F,$$

and if one assumes that, for $0 < i \leq n$, F_i and F_i/F_{i-1} are objects of $\mathcal{D}$, then

$$f(F) = \sum_{i=1}^{n} f(F_i/F_{i-1}).$$

$\varphi)$ If $\mathcal{D}$ is stable under infinite direct sums, then $f = 0$.

[22] SGA 6 I

To prove δ), one uses the exact sequences

$$0 \longrightarrow Z^i \longrightarrow E^i \longrightarrow B^{i+1} \longrightarrow 0,$$

$$0 \longrightarrow B^i \longrightarrow Z^i \longrightarrow H^i(E) \longrightarrow 0.$$

The proof of ε) is by induction on n, using the exact sequence

$$0 \longrightarrow F_{n-1} \longrightarrow F \longrightarrow F/F_{n-1} \longrightarrow 0.$$

To prove φ), let $E \in \operatorname{ob}\mathcal{D}$ and

$$F = \bigoplus_{n\in\mathbb{Z}^+} E_n, \qquad E_n = E, \quad n \in \mathbb{Z}^+.$$

Then $E \oplus F \simeq F$, and applying γ) gives

$$f(F) = f(F) + f(E),$$

hence $f(E) = 0$.

If, for every abelian group G, one considers the abelian group $A_{\mathcal{D}}(G)$ of additive functions from $\mathcal{D}$ to G, one obtains in an evident way a covariant functor

$$A_{\mathcal{D}} : \mathrm{Ab} \longrightarrow \mathrm{Ab}\,.$$

The functor $A_{\mathcal{D}}$ is representable. A representing pair $(K_{\mathcal{D}}(\mathcal{C}), \varphi)$ may be obtained as follows. Let L be the free abelian group generated by the objects of $\mathcal{D}$, and let R be the subgroup of L generated by the elements of the form $E - E' - E''$ for each exact sequence

$$0 \longrightarrow E' \longrightarrow E \longrightarrow E'' \longrightarrow 0$$

of $\mathcal{C}$. Put

$$K_{\mathcal{D}}(\mathcal{C}) = L/R.$$

The map φ is obtained by composing the two canonical maps

$$\operatorname{ob}\mathcal{D} \longrightarrow L \longrightarrow L/R.$$

When there is no danger of confusion, one may abbreviate the notation:

$$K_{\mathcal{D}}(\mathcal{C}) = K(\mathcal{D}).$$

2. The case of triangulated categories

Let $\mathcal{C}$ be a triangulated category and let G be an abelian group. A function f from $\mathcal{C}$ to G is said to be additive if, for every distinguished triangle

$$\begin{array}{ccccc} & & Z & & \\ & {\scriptstyle w}\swarrow & & \nwarrow{\scriptstyle v} & \\ X & & \xrightarrow[u]{} & & Y \end{array}$$

one has

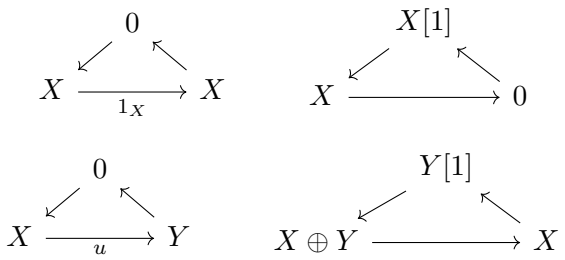
$$f(Y) = f(X) + f(Z).$$

Given an additive function f, the following relations are immediate consequences of the definition:

$$\text{a) } f(0) = 0, \qquad \text{b) } f(X[n]) = (-1)^n f(X),$$

$$\text{c) } f(X) = f(Y) \text{ if } X \text{ and } Y \text{ are isomorphic}, \qquad \text{d) } f(X \oplus Y) = f(X) + f(Y).$$

Indeed the following triangles are distinguished:

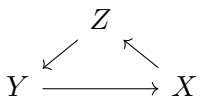


(u an isomorphism). To form the last triangle, we used the fact that the sum of two distinguished triangles is distinguished.

As in the case of abelian categories, one obtains in an evident way a functor

$$A : \mathrm{Ab} \longrightarrow \mathrm{Ab}$$

which associates to each abelian group G the abelian group $A(G)$ of additive functions on $\mathcal{C}$ with values in G. This functor is representable, and it is easy to construct a representing pair $(K(\mathcal{C}), \mathrm{cl}_{\mathcal{C}})$. Namely, one first considers the free abelian group $\mathbb{Z}^{(\mathrm{ob}\,\mathcal{C})}$ generated by the objects of $\mathcal{C}$, and then the subgroup R generated by the elements of the form $X - Y - Z$, where



is a distinguished triangle. The quotient group $\mathbb{Z}^{(\mathrm{ob}\,\mathcal{C})}/R$ is $K(\mathcal{C})$, and $\mathrm{cl}_{\mathcal{C}}$ is obtained by composing the two canonical maps

$$\mathrm{ob}\,\mathcal{C} \longrightarrow \mathbb{Z}^{(\mathrm{ob}\,\mathcal{C})} \longrightarrow K(\mathcal{C}).$$

3. Functorial character

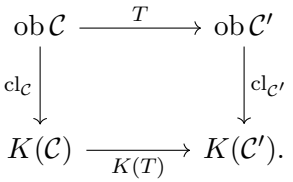
Let $\mathcal{C}$ and $\mathcal{C}'$ be two triangulated categories, and let $T : \mathcal{C} \to \mathcal{C}'$ be an exact functor from $\mathcal{C}$ to $\mathcal{C}'$, that is, an additive "graded" functor carrying distinguished triangles to distinguished triangles. Denote, as above, by

$$A, A' : \mathrm{Ab} \longrightarrow \mathrm{Ab}$$

the functors associated with the categories $\mathcal{C}$ and $\mathcal{C}'$. There results a functorial morphism $A' \to A$ given by composition with T, hence a homomorphism

$$K(T) : K(\mathcal{C}) \longrightarrow K(\mathcal{C}')$$

uniquely determined by the commutativity of the diagram



It follows that, if the functors $T, T_1 : \mathcal{C} \to \mathcal{C}'$ are isomorphic, then $K(T) = K(T_1)$. In particular, if T is an equivalence of categories, then $K(T)$ is an isomorphism.

If $\mathcal{C}''$ is a third triangulated category and

$$F : \mathcal{C} \times \mathcal{C}' \longrightarrow \mathcal{C}''$$

is a bifunctor exact in each variable, then it is clear that there results a bilinear map

$$K(F) : K(\mathcal{C}) \times K(\mathcal{C}') \longrightarrow K(\mathcal{C}'')$$

such that the following relation holds:

$$K(F)(\mathrm{cl}_{\mathcal{C}}(X), \mathrm{cl}_{\mathcal{C}'}(X')) = \mathrm{cl}_{\mathcal{C}''}(F(X, X')).$$

Proposition 3.1. Let $\mathcal{A}$ be a triangulated category, $\mathcal{B}$ a thick triangulated subcategory of $\mathcal{A}$, $\mathcal{A}/\mathcal{B}$ the quotient category of $\mathcal{A}$ by $\mathcal{B}$, $Q : \mathcal{A} \to \mathcal{A}/\mathcal{B}$ the canonical quotient functor, and $i : \mathcal{B} \to \mathcal{A}$ the inclusion functor. Then the following sequence is exact:

$$K(\mathcal{B}) \xrightarrow{K(i)} K(\mathcal{A}) \xrightarrow{K(Q)} K(\mathcal{A}/\mathcal{B}) \longrightarrow 0.$$

Proof. It is clear that there is a natural homomorphism

$$\mathrm{Coker}(K(i)) \xrightarrow{\alpha} K(\mathcal{A}/\mathcal{B}).$$

On the other hand, there is an evident map

$$\mathrm{ob}(\mathcal{A}/\mathcal{B}) \xrightarrow{\gamma} \mathrm{Coker}(K(i)),$$

since $\mathrm{ob}(\mathcal{A}/\mathcal{B}) = \mathrm{ob}(\mathcal{A})$. Let $X, Y \in \mathrm{ob}(\mathcal{A}/\mathcal{B})$ and suppose that they are isomorphic. We want to show that $\gamma(X) = \gamma(Y)$. The category $\mathcal{A}/\mathcal{B}$ is obtained by a calculus of fractions on the right or on the left, the multiplicative system S being formed by the morphisms f which are contained in a distinguished triangle (X', Y', Z', f, g, h) in which Z' is an object of $\mathcal{B}$. (S is a saturated multiplicative system.) It follows that there exist X_1 and morphisms

$$X_1 \xrightarrow{s} X, \qquad X_1 \xrightarrow{t} Y$$

such that $s, t \in S$. It is therefore enough to prove that $\gamma(X) = \gamma(X_1)$, and this follows from the fact that there is a distinguished triangle of the form

$$(X_1, X, Z, s, \ldots),$$

with $Z \in \mathrm{ob}\,\mathcal{B}$.

The map γ is an additive function. Indeed, if (X, Y, Z, f, g, h) is a distinguished triangle of $\mathcal{A}/\mathcal{B}$, one must prove that

$$\gamma(X) + \gamma(Z) = \gamma(Y).$$

But the relation now follows because the triangle (X, Y, Z, f, g, h) is isomorphic to a distinguished triangle of $\mathcal{A}$. Consequently one obtains

$$\beta : K(\mathcal{A}/\mathcal{B}) \longrightarrow \mathrm{Coker}(K(i)),$$

and it is immediate to check that β is the inverse of α.

4. Comparison with the case of abelian categories

Let $\mathcal{C}$ be an abelian category and $D(\mathcal{C})$ the derived category of $\mathcal{C}$. As usual, denote by $D^b(\mathcal{C})$ the full subcategory of $D(\mathcal{C})$ generated by the bounded complexes. By associating with every object X of $\mathcal{C}$ the complex whose components are all zero except the component in dimension zero, which is equal to X, one obtains a homomorphism

$$K(\mathcal{C}) \xrightarrow{\mu} K(D^b(\mathcal{C})).$$

This homomorphism is in fact an isomorphism. Indeed, we may use Proposition 3.1 to construct an inverse to μ, taking into account that

$$D^b(\mathcal{C}) \simeq K^{b,b}(\mathcal{C})/K^{b,\phi}(\mathcal{C}),$$

where $K^{b,\phi}(\mathcal{C})$ is the thick subcategory of $K^{b,b}(\mathcal{C})$ consisting of the acyclic complexes. Let $X^\bullet = (X_i) \in \mathrm{ob}(K^{b,b}(\mathcal{C}))$. If one sets

$$f(X^\bullet) = \sum_i (-1)^i \,\mathrm{cl}_{\mathcal{C}}(X_i),$$

one obtains an additive function from $K^{b,b}(\mathcal{C})$ with values in $K(\mathcal{C})$. Indeed, one first observes that, if $X^\bullet$ and $Y^\bullet$ are homotopic, then $f(X^\bullet) = f(Y^\bullet)$, since $f(X^\bullet) = f(H(X^\bullet))$. It follows that there is a homomorphism

$$K(D^b(\mathcal{C})) \xrightarrow{\nu} K(\mathcal{C}),$$

and it is immediate to check that it is the inverse of μ.

Since the invariant $K(\mathcal{C})$ is often of no interest when $\mathcal{C}$ is too large, it is useful to relativize it with respect to a subcategory $\mathcal{C}_o$ of $\mathcal{C}$. Thus let $\mathcal{C}_o$ be a full subcategory of $\mathcal{C}$. We may define, on the one hand, the group

$$K_o(\mathcal{C}) = K_{\mathcal{C}_o}(\mathcal{C}).$$

Suppose, on the other hand, that the following condition is satisfied:

$$(A) \qquad \mathcal{C}_o \text{ is stable under finite direct sums.}$$

It is then easy to define the triangulated category $D^b_o(\mathcal{C})$ by using complexes in $\mathcal{C}$ with bounded cohomology and with components in the subcategory $\mathcal{C}_o$, and passing to the quotient by quasi-isomorphisms of such complexes. As above, there results a homomorphism

$$(*) \qquad K_o(\mathcal{C}) \longrightarrow K(D^b_o(\mathcal{C})).$$

Suppose that the subcategory $\mathcal{C}_o$ also satisfies the following condition (B):

$$(B) \qquad \text{If } X, Y \in \mathrm{ob}\,\mathcal{C}_o \text{ and } X \xrightarrow{u} Y \text{ is an epimorphism (in } \mathcal{C}\text{, of course)},$$

then $\mathrm{Ker}\, u \in \mathrm{ob}\,\mathcal{C}_o$. Reasoning as above, one can show that the homomorphism $(*)$ is an isomorphism.

The canonical inclusion functor

$$D^b_o(\mathcal{C}) \longrightarrow D^b(\mathcal{C})$$

is not fully faithful in general. However:

Proposition 4.1. Suppose that the subcategory $\mathcal{C}_o$ satisfies conditions (A), (B), and the following condition (C):

(C) Every diagram $\begin{array}{ccc} A & \xrightarrow{u} & B \\ & & \uparrow{\scriptstyle v} \\ & & L \end{array}$

where u is an epimorphism and $L \in \mathrm{ob}\,\mathcal{C}_o$, can be completed to a commutative diagram

$$\begin{array}{ccc} A & \xrightarrow{u} & B \\ \uparrow & & \uparrow{\scriptstyle v} \\ L_1 & \xrightarrow[w]{} & L \end{array}$$

such that $L_1 \in \mathrm{ob}\,\mathcal{C}_o$ and w is an epimorphism. Under these conditions, the canonical functors

$$D^b_o(\mathcal{C}) \longrightarrow D^b(\mathcal{C}), \qquad D^-_o(\mathcal{C}) \longrightarrow D^-(\mathcal{C})$$

are fully faithful. Moreover, the essential image of $D^b_o(\mathcal{C})$ (resp. $D^-_o(\mathcal{C})$) is stable under direct factors.

The proof of this proposition essentially uses a criterion of Verdier ([2], 4–2 Theorem) and will be given in the first exposé of the seminar on Riemann-Roch (SGA 6 I 2.7).

Corollary. Suppose, in addition, that the subcategory $\mathcal{C}_o$ is stable under Ker and Coker, hence is an abelian category, and denote by $D^b(\mathcal{C})_o$ the full triangulated subcategory of $D^b(\mathcal{C})$ generated by the complexes of $D^b(\mathcal{C})$ whose cohomology objects are isomorphic to objects of $\mathcal{C}_o$. Then the inclusion functor

$$D^b(\mathcal{C}_o) \longrightarrow D^b(\mathcal{C})_o$$

is an equivalence between the two categories, and consequently one obtains the sequence of isomorphisms

$$K(\mathcal{C}_o) \simeq K_o(\mathcal{C}) \simeq K(D^b(\mathcal{C}_o)) \simeq K(D^b(\mathcal{C})_o). \qquad (*)$$

Observation. Suppose that the subcategory $\mathcal{C}_o$ satisfies conditions (A) and (B), and that every object of $\mathcal{C}$ admits a finite resolution on the left by elements of $\mathcal{C}_o$. In this case, $\mathcal{C}_o$ also satisfies condition (C), and the canonical functor

$$D^b_o(\mathcal{C}) \longrightarrow D^b(\mathcal{C})$$

is in fact an equivalence of categories. Consequently, one has the isomorphism

$$K_{\mathcal{C}_o}(\mathcal{C}) \simeq K(\mathcal{C}).$$

23

[23] cf. (SGA 6 IV 1.6).

5. Pseudo-coherent complexes

Let $\mathcal{C}$ be an abelian category and $\mathcal{C}_o$ a full subcategory of $\mathcal{C}$ satisfying conditions (A), (B), (C). We shall denote by $D_o^-(\mathcal{C})_{\mathrm{coh}}$ the essential image of $D_o^-(\mathcal{C})$ under the canonical functor

$$D_o^-(\mathcal{C}) \longrightarrow D(\mathcal{C}).$$

The objects of $D_o^-(\mathcal{C})_{\mathrm{coh}}$ will be called $\mathcal{C}_o$-pseudo-coherent complexes. Thus a complex of $\mathcal{C}$ is $\mathcal{C}_o$-pseudo-coherent if it is isomorphic in $D(\mathcal{C})$ to a bounded-above complex whose components are objects of $\mathcal{C}_o$.

The category $D_o^-(\mathcal{C})_{\mathrm{coh}}$ is a triangulated subcategory of $D(\mathcal{C})$, in the sense that every distinguished triangle of $D(\mathcal{C})$ with two vertices in the subcategory $D_o^-(\mathcal{C})_{\mathrm{coh}}$ is isomorphic to a triangle whose three objects are in the subcategory $D_o^-(\mathcal{C})_{\mathrm{coh}}$.

First, it is clear that the subcategory $D_o^-(\mathcal{C})_{\mathrm{coh}}$ is stable under the translation automorphism $T : D(\mathcal{C}) \to D(\mathcal{C})$. Therefore, to prove that $D_o^-(\mathcal{C})_{\mathrm{coh}}$ is a triangulated subcategory of $D(\mathcal{C})$, it is enough to check that if $U^\bullet$, $V^\bullet$ are objects of $D_o^-(\mathcal{C})_{\mathrm{coh}}$ and if the triangle

$$\begin{array}{ccc} & W^\bullet & \\ {\scriptstyle w}\swarrow & & \nwarrow{\scriptstyle v} \\ U^\bullet & \xrightarrow[u]{} & V^\bullet \end{array}$$

is distinguished for the triangulated category structure of $D(\mathcal{C})$, then $W^\bullet$ is also an object of $D_o^-(\mathcal{C})_{\mathrm{coh}}$. By hypothesis, there exist complexes $X^\bullet$, $Y^\bullet$, isomorphic in $D(\mathcal{C})$ to $U^\bullet$ and $V^\bullet$ respectively, whose components are objects of $\mathcal{C}_o$. We obtain a commutative square in $D(\mathcal{C})$:

$$\begin{array}{ccc} U^\bullet & \xrightarrow{u} & V^\bullet \\ {\scriptstyle\sim}\downarrow & & \downarrow{\scriptstyle\sim} \\ X^\bullet & \xrightarrow[f]{} & Y^\bullet. \end{array}$$

But, after replacing $X^\bullet$ by another isomorphic complex, we may suppose, using the fact that the inclusion functor

$$D_o^-(\mathcal{C}) \longrightarrow D^-(\mathcal{C})$$

is fully faithful (Prop. 4.1), that f is an actual morphism of complexes. Let $Z^\bullet$ be the mapping cylinder of f, and let $g : Y^\bullet \to Z^\bullet$ be the canonical morphism. By the construction itself, the components of $Z^\bullet$ are objects of $\mathcal{C}_o$ (condition (A)). On the other hand,

$$\begin{array}{ccc} & Z^\bullet & \\ {\scriptstyle h}\swarrow & & \nwarrow{\scriptstyle g} \\ X^\bullet & \xrightarrow[f]{} & Y^\bullet \end{array}$$

being a distinguished triangle in $D(\mathcal{C})$, it follows that $Z^\bullet$ is isomorphic to $W^\bullet$.

The category $D_o^-(\mathcal{C})_{\mathrm{coh}}$ is therefore endowed with a structure of triangulated category: a triangle in $D_o^-(\mathcal{C})_{\mathrm{coh}}$ is distinguished if and only if it is distinguished in the triangulated category $D(\mathcal{C})$.

The intersection of $D_o^-(\mathcal{C})_{\mathrm{coh}}$ with $D^b(\mathcal{C})_{\mathrm{coh}}$ will be denoted by $D_o^b(\mathcal{C})_{\mathrm{coh}}$.

An object M of $\mathcal{C}$ will be called pseudo-coherent if it is so as a complex reduced to degree zero; one proves that it is necessary and sufficient for this that it admit a resolution on the left whose components are objects of $\mathcal{C}_o$.

Proposition 5.1. A complex X is $\mathcal{C}_o$-pseudo-coherent if and only if it is isomorphic to a complex which is bounded on the right and whose components are $\mathcal{C}_o$-pseudo-coherent.

The proof of this proposition will appear in the first exposé of the seminar on Riemann-Roch (SGA 6 I 2.7).

6. Perfect complexes

An object of the category $D(\mathcal{C})$ will be called a $\mathcal{C}_o$-perfect complex if it is isomorphic to an object of $D^b_o(\mathcal{C})$, that is, to a bounded complex all of whose components are in $\mathcal{C}_o$. We shall denote by $D_o(\mathcal{C})_{\mathrm{parf}}$ the full subcategory of $D(\mathcal{C})$ generated by the perfect complexes.

Thus the category $D_o(\mathcal{C})_{\mathrm{parf}}$ is nothing other than the essential image of $D^b_o(\mathcal{C})$ under the inclusion functor

$$D^b_o(\mathcal{C}) \longrightarrow D(\mathcal{C}).$$

It is easy to see that $D_o(\mathcal{C})_{\mathrm{parf}}$ is a triangulated subcategory of $D(\mathcal{C})$, and hence is endowed with a structure of triangulated category.

7. An important special case

Let A be a ring and let $\mathcal{C}$ be the category of A-modules, on the left for example. Denote by $\mathcal{C}_o$ the full subcategory of $\mathcal{C}$ generated by the projective A-modules of finite type. The subcategory $\mathcal{C}_o$ satisfies conditions (A), (B), (C). In this case we use the following notation:

$$D^-(A)_{\mathrm{coh}} = D^-_o(\mathcal{C})_{\mathrm{coh}}, \qquad D^b(A)_{\mathrm{coh}} = D^b_o(\mathcal{C})_{\mathrm{coh}},$$

$$D(A)_{\mathrm{parf}} = D_o(\mathcal{C})_{\mathrm{parf}}.$$

The complexes of $D(\mathcal{C})$ which are $\mathcal{C}_o$-pseudo-coherent (resp. $\mathcal{C}_o$-perfect) will simply be called pseudo-coherent (resp. perfect) complexes.

It will be useful to consider the following groups:

$$K_\bullet(A) = K(D^b(A)_{\mathrm{coh}}),$$

$$K^\bullet(A) = K(D(A)_{\mathrm{parf}}).$$

As for the group $K^\bullet(A)$, we have, by Proposition 4.1 and its corollary,

$$K^\bullet(A) = K(D(A)_{\mathrm{parf}}) \simeq K(D^b_o(\mathcal{C})) \simeq K_{\mathcal{C}_o}(\mathcal{C}),$$

which shows that it is also the classical group of classes of projective modules of finite type over A.

In the special case where A is noetherian, the group $K_\bullet(A)$ also admits a classical description. For this, let $\mathcal{C}_1$ be the abelian category of modules of finite type. Then

$$K_\bullet(A) \simeq K(\mathcal{C}_1).$$

Indeed, using Proposition 4.1, one has

$$K(\mathcal{C}_1) \simeq K(D^b(\mathcal{C}_1)) \simeq K(D^b_{\mathcal{C}_1}(\mathcal{C})),$$

because $D^b(\mathcal{C}_1) \simeq D^b_{\mathcal{C}_1}(\mathcal{C})$ immediately.

In fact, if A is noetherian and $L^\bullet \in D^-(A)$, then it follows from Proposition 5.1 that $L^\bullet$ is pseudo-coherent if and only if the $H^i(L^\bullet)$ are of finite type.

For an arbitrary ring A, one has a homomorphism

$$K^\bullet(A) \xrightarrow{\widetilde{\gamma}_A} K_\bullet(A),$$

which comes from the inclusion functor

$$(*) \qquad D(A)_{\text{parf}} \longrightarrow D^b(A)_{\text{coh}}.$$

In general, the homomorphism $\widetilde{\gamma}_A$ is neither injective nor surjective. In the special case of a regular ring A, every A-module M of finite type has finite projective dimension and it follows, thanks to 5.1, that the inclusion functor $(*)$ is in fact an equivalence between the two categories. In that case, $\widetilde{\gamma}_A$ is therefore an isomorphism.

8. Tor of complexes

Let A be a not necessarily commutative ring, and let ${}_A\mathcal{C}$ (resp. $\mathcal{C}_A$) be the abelian category of left (resp. right) A-modules. By $K^-({}_A\mathcal{C})$ we shall denote the triangulated category of complexes of ${}_A\mathcal{C}$ bounded above, and by ${}_A\mathcal{D}$ the full triangulated subcategory of $K^-({}_A\mathcal{C})$ consisting of complexes whose components are flat left A-modules.

Let $X^\bullet$ be an object of $K^-(\mathcal{C}_A)$, and consider the functor

$$\Phi_{X^\bullet} = X^\bullet \otimes_A \cdot \ : \ K^-({}_A\mathcal{C}) \longrightarrow K^-(\text{Ab}).$$

Under these conditions, the following propositions hold.

1) Every acyclic object of ${}_A\mathcal{D}$ is transformed by $\Phi_{X^\bullet}$ into an acyclic object of $K^-(\text{Ab})$. Indeed, if $N^\bullet$ is an object of ${}_A\mathcal{D}$ such that $Z^i(N^\bullet)$, $B^i(N^\bullet)$, and $H^i(N^\bullet)$ are flat, one has the classical isomorphism

$$\bigoplus_{p+q=n} H_p(X^\bullet) \otimes H_q(N^\bullet) \longrightarrow H_n(X^\bullet \otimes_A N^\bullet).$$

2) Every object $Y^\bullet$ of $K^-({}_A\mathcal{C})$ is the target of a quasi-isomorphism whose source is an object of ${}_A\mathcal{D}$. It is enough for this to take a Cartan-Eilenberg resolution. We can therefore apply Theorem 2 of §2, no. 2 of [2] to conclude that $\Phi_{X^\bullet}$ admits a left derived functor:

$$\mathbf{L}\Phi_{X^\bullet} : D^-({}_A\mathcal{C}) \longrightarrow D^-(\text{Ab}).$$

The object $\mathbf{L}\Phi_{X^\bullet}(Y^\bullet)$ may be obtained, up to isomorphism, as follows. Let $P^\bullet$ be an object of ${}_A\mathcal{D}$ and let $P^\bullet \to Y^\bullet$ be a quasi-isomorphism. Then $\mathbf{L}\Phi_{X^\bullet}(Y^\bullet)$ is isomorphic to

$$Q(X^\bullet \otimes_A P^\bullet),$$

where, as usual, Q denotes the canonical functor

$$K^-(\mathrm{Ab}) \longrightarrow D^-(\mathrm{Ab}).$$

It follows that for each object $Y^\bullet$ of $D^-({}_A\mathcal{C})$, the functor

$$K^-(\mathcal{C}_A) \longrightarrow D^-(\mathrm{Ab}), \qquad X^\bullet \longmapsto \mathbf{L}\Phi_{X^\bullet}(Y^\bullet)$$

is exact and vanishes on acyclic complexes, hence gives an exact bifunctor

$$D^-(\mathcal{C}_A) \times D^-({}_A\mathcal{C}) \longrightarrow D^-(\mathrm{Ab}),$$

$$(X^\bullet, Y^\bullet) \longmapsto X^\bullet \overset{\mathbf{L}}{\otimes}_A Y^\bullet.$$

Passing to homology, one defines the $\mathrm{Tor}_i^A(X^\bullet, Y^\bullet)$ (cf. also [1], 6.3). In the particular case of a commutative ring A, one obtains in fact an exact bifunctor

$$D^-(\mathcal{C}) \times D^-(\mathcal{C}) \longrightarrow D^-(\mathcal{C}),$$

the tensor product in the sense of derived categories ($\mathcal{C} = {}_A\mathcal{C} = \mathcal{C}_A$).

Definition. We shall say that the complex X of $D(\mathcal{C}_A)$ has finite Tor-dimension if it lies in D^- and if there exists $n_o \in \mathbb{Z}^+$ such that

$$\mathrm{Tor}_n^A(X, Y) = 0$$

for every $Y \in \mathrm{ob}({}_A\mathcal{C})$ and every $n > n_o$.

We shall use the notion of Tor-dimension to obtain a characterization of perfect complexes.

Proposition 8.1. Let A be a not necessarily commutative ring and let $L^\bullet$ be a complex of A-modules. The following conditions are equivalent:

a) $L^\bullet$ is perfect;

b) $L^\bullet$ is pseudo-coherent, has bounded cohomology, and has finite Tor-dimension.[24]

For the proof, one uses the following lemma.

Lemma. (Bourbaki, Alg. Comm. I, §2, ex. 15). Every A-module E which is flat and of finite presentation is projective.

Proof of the lemma. Let $u : F \to F'$ be an epimorphism. We must prove that

$$\mathrm{Hom}_A(E, F) \longrightarrow \mathrm{Hom}_A(E, F')$$

is an epimorphism. It is enough to prove that, for every divisible group G,

$$\mathrm{Hom}_{\mathbb{Z}}(\mathrm{Hom}_A(E, F'), G) \longrightarrow \mathrm{Hom}_{\mathbb{Z}}(\mathrm{Hom}_A(E, F), G)$$

[24] cf. SGA 6 I 5.8.1.

is a monomorphism. But the diagram

$$\begin{array}{ccc} \mathrm{Hom}_{\mathbb{Z}}(\mathrm{Hom}_A(E,F'),G) & \longrightarrow & \mathrm{Hom}_{\mathbb{Z}}(\mathrm{Hom}_A(E,F),G) \\ \sim\downarrow & & \downarrow\sim \\ \mathrm{Hom}_{\mathbb{Z}}(F',G)\otimes_A E & \longrightarrow & \mathrm{Hom}_{\mathbb{Z}}(F,G)\otimes_A E \end{array}$$

is commutative, and the vertical arrows are isomorphisms, by the hypothesis on E.

Proof of Proposition 5.2. The implication a) $\Rightarrow$ b) is immediate. To prove b) $\Rightarrow$ a), let

$$\cdots \longrightarrow P_n \xrightarrow{d_n} \cdots \longrightarrow P_i \longrightarrow 0 \longrightarrow \cdots$$

be a complex isomorphic to $L^\bullet$ in $D(\mathcal{C})$, where the P_j are projective A-modules of finite type. Since $L^\bullet$ has finite Tor-dimension and bounded cohomology, it follows that there exists $n_o \in \mathbb{Z}$ such that:

I) The sequence

$$\cdots \longrightarrow P_{n_o-p} \xrightarrow{d_{n_o-p}} \cdots \longrightarrow P_{n_o} \longrightarrow \mathrm{Ker}\, d_{n_o+1} \longrightarrow 0$$

is exact.

II) $\mathrm{Ker}\, d_{n_o+1}$ is flat.

III) The complex

$$0 \longrightarrow \mathrm{Ker}\, d_{n_o+1} \longrightarrow P_{n_o+1} \longrightarrow \cdots \longrightarrow P_i \longrightarrow 0 \longrightarrow \cdots$$

is isomorphic to $L^\bullet$ in $D(\mathcal{C})$.

But $\mathrm{Ker}\, d_{n_o+1}$ is of finite presentation, hence projective of finite type by the lemma, which proves 8.1.

If A is a commutative ring, and if $X^\bullet$, $Y^\bullet$ are two perfect complexes, then their tensor product

$$X^\bullet \overset{\mathbf{L}}{\otimes}_A Y^\bullet$$

in the derived category is again a perfect complex. We obtain a bifunctor

$$D(A)_{\mathrm{parf}} \times D(A)_{\mathrm{parf}} \longrightarrow D(A)_{\mathrm{parf}}$$

which is exact in each variable. Consequently, one defines a product on $K^\bullet(A)$, and it is easy to see that $K^\bullet(A)$ is thereby endowed with the structure of a commutative ring with unit. In fact, $K^\bullet(A)$ can be endowed with the structure of a λ-ring; for details, see the seminar on Riemann-Roch following this one.[25]

The tensor product

$$X^\bullet \overset{\mathbf{L}}{\otimes}_A Y^\bullet$$

of a perfect complex $X^\bullet$ and a bounded pseudo-coherent complex $Y^\bullet$ is a bounded pseudo-coherent complex (A still a commutative ring). Consequently, one can introduce on $K_\bullet(A)$ the structure of a $K^\bullet(A)$-module.

[25] SGA 6 V 2.

9. Functorial properties

a) Let A and B be two not necessarily commutative rings, and let $u : A \to B$ be a homomorphism. Every left (resp. right) B-module M can be endowed with the structure of a left (resp. right) A-module, denoted $M_{[u]}$. In particular, $B_{[u]}$ is a right A-module.

The functor

$$E \longmapsto B_{[u]} \otimes_A E$$

allows one to define the exact functor

$$D(A)_{\mathrm{parf}} \longrightarrow D(B)_{\mathrm{parf}}$$

and consequently the homomorphism

$$K^\bullet(A) \xrightarrow{u^*} K^\bullet(B).$$

Thus one obtains a covariant functor from the category of rings (resp. commutative rings) to the category of abelian groups (resp. commutative rings).

b) Suppose now that the left A-module $B_{[u]}$ is pseudo-coherent. It follows that the functor

$$F \longmapsto F_{[u]}$$

transforms a free B-module of finite type into a pseudo-coherent A-module. By using Proposition 5.1, one obtains an exact functor

$$D^b(B)_{\mathrm{coh}} \longrightarrow D^b(A)_{\mathrm{coh}}$$

and consequently a canonical homomorphism

$$K_\bullet(B) \xrightarrow{u_*} K_\bullet(A).$$

The homomorphisms u_* and u^* satisfy the following identity ("the projection formula"):

$$u_*(u^*(\alpha) \cdot \beta) = \alpha\,(u_*(\beta)) \quad \text{for } \alpha \in K^\bullet(A),\ \beta \in K_\bullet(B).$$

This easy formula will be proved in a more general form in the exposés of the seminar on Riemann-Roch (SGA 6 IV 2.11.1.2).

10. Relative construction[26]

Let $u : A \to B$ be a homomorphism of rings, and let

$$D(B) \longrightarrow D(A)$$

be the associated exact functor. In $D(B)$, we can consider the complexes that are pseudo-coherent relative to A, those of finite Tor-dimension relative to A, and also the complexes perfect relative to A. In particular, it is natural to consider the triangulated subcategories

$$D(B)_{A-\mathrm{parf}}, \qquad D^b(B)_{A-\mathrm{coh}}$$

[26] cf. (SGA 6 III, IV).

of $D(B)$ generated by the complexes that are perfect, respectively pseudo-coherent and bounded, relative to A. These two triangulated categories allow one to define the following groups:

$$K^\bullet(B \text{ rel } A) = K(D(B)_{A-\text{parf}}),$$

$$K_\bullet(B \text{ rel } A) = K(D^b(B)_{A-\text{coh}}).$$

Examples. Let G be a group and let Λ be a commutative ring. The homomorphism

$$\Lambda \xrightarrow{\varepsilon} \Lambda[G]$$

therefore allows one to define the groups

$$K^\bullet(\Lambda[G] \text{ rel } \Lambda), \qquad K_\bullet(\Lambda[G] \text{ rel } \Lambda),$$

which will be denoted by

$$R^\bullet_\Lambda(G), \qquad R^\Lambda_\bullet(G).$$

In fact, $R^\bullet_\Lambda(G)$ is a commutative ring and $R^\Lambda_\bullet(G)$ is a module over it.

Remarks.

a) If the ring Λ is not necessarily commutative, one may set, by definition,

$$\Lambda[G] = \Lambda \otimes_{\mathbb{Z}} \mathbb{Z}G$$

and consequently obtains a homomorphism

$$\Lambda \xrightarrow{\varepsilon} \Lambda[G].$$

In this way, one may give a meaning to the groups $R^\bullet_\Lambda(G)$ and $R^\Lambda_\bullet(G)$ even when Λ is non-commutative.

b) The preceding construction can be generalized to the case of a group prescheme, or of a pro-prescheme in groups, G over $\operatorname{Spec}\Lambda$, by starting from the abelian category of Λ-modules on which G operates; this is no longer made explicit in terms of modules over a ring. One then uses the natural inclusion functor into the category of Λ-modules. If Λ is a field, it can be made explicit in terms of modules over a pro-ring, and in the general case, in terms of comodules, at least if G is affine over Λ; cf. SGA 3 I 4.7.2).

Exposé X — Euler–Poincaré Formula in Étale Cohomology

EULER–POINCARÉ FORMULA IN ÉTALE COHOMOLOGY

by A. Grothendieck

(written up by I. Bucur)

The purpose of the present exposé is to state and prove formula (7.2), of Euler–Poincaré type. This formula generalizes a formula obtained independently by Ogg and Chafarevitch, whose results are presented (from the viewpoint of étale cohomology) in M. Raynaud's exposé [1].

The Euler–Poincaré formula uses in an essential way the formalism of derived categories. As in loc. cit. the proof is made through a variant (5.1) of a well-known formula of Weil.

1. Sheaves on a scheme with operators

Let X be a scheme endowed with a group G acting by automorphisms. Proceeding as in ([T] chap. V), one may define the notion of an étale sheaf on X with group of operators G, or simply a "sheaf on $(X_{\text{ét}}, G)$".

By definition, to give an étale sheaf on X with group of operators G is to give a sheaf $F \in \mathrm{ob}(\widetilde{X}_{\text{ét}})$ and a morphism

$$S_g : F \longrightarrow g^*(F)$$

for each $g \in G$, in such a way that the following conditions are satisfied:

$$\text{a)} \quad S_e = 1_F,$$

and, for $g, h \in G$, the diagram

$$\begin{array}{ccc} F & \xrightarrow{S_{hg}} & (hg)^*(F) \\ {\scriptstyle S_h}\downarrow & & \downarrow{\scriptstyle C_{h,g}(F)} \\ h^*(F) & \xrightarrow[h^*(S_g)]{} & h^*(g^*(F)) \end{array}$$

is commutative, where

$$C_{h,g}(F) : (hg)^*(F) \longrightarrow h^*(g^*(F))$$

is the canonical isomorphism.

Morphisms between two sheaves (F, S_g), (F', S'_g) on X with group of operators G are defined in the evident way, and one obtains a category $\widetilde{X}_{\text{ét},G}$ which is a topos, as follows readily from Giraud's criterion (SGA 4 II 4.12).

Given a ring A of $\widetilde{X}_{\text{ét},G}$, one may consider the abelian category of A-modules, which will be denoted $\mathrm{Mod}(A)$.

For example, given a ring Λ, one may equip the constant sheaf Λ_X associated with Λ with the trivial structure of a sheaf with group of operators G, using the canonical transitivity isomorphisms

$$S_g : \Lambda_X \xrightarrow{\sim} g^*(\Lambda_X).$$

All the results proved in [1], chap. V, can be extended to this setting, and we leave the details to the reader.

2. Where one proves that a certain complex of $\Lambda[G]$-modules is perfect

Recall the following result of SGA 4 XVII.

Lemma 2.1. Let X and Y be two schemes and let $f : X \to Y$ be a proper morphism, with Y quasi-compact. Let A be a torsion ring, and let $F^\bullet$ be a complex of sheaves of A-modules on X of finite Tor-dimension (SGA 4 XVII). Then $Rf_*(F^\bullet)$ is of finite Tor-dimension.

Proposition 2.2. Let X be a scheme proper over a separably closed field k, let G be a finite group acting on X, and let V be an open subset of X stable under G and such that G acts admissibly (SGA 1 V 1.7) and freely on V. Let $\Lambda = \mathbb{Z}/\ell^n\mathbb{Z}$, with ℓ a prime number different from the characteristic of k, and let Λ_V be the constant sheaf on V associated with Λ, endowed with its trivial structure of a sheaf with group of operators G. Let

$$i : V \longrightarrow X$$

be the immersion of V into X, and put $\Lambda_{V,X} = i_!(\Lambda_V)$. Under these conditions the complex of $\Lambda[G]$-modules

$$R\Gamma_X(\Lambda_{V,X})$$

is a perfect complex (VIII 7).

Proof. If $p : X \to Y = X/G$ is the canonical projection, it is well known that there is a canonical isomorphism

$$R\Gamma_X(\Lambda_{V,X}) \simeq R\Gamma_Y(Rp_*(\Lambda_{V,X}))$$

in the category $D(\Lambda[G])$. On the other hand, the complex $Rp_*(\Lambda_{V,X})$ of $\Lambda[G]$-modules on Y is of finite Tor-dimension. Indeed, since $p : X \to Y$ is a finite morphism of schemes, one has

$$R^q p_*(\Lambda_{V,X}) = 0 \qquad (q \neq 0)$$

(SGA 4 VIII 5.5). Hence

$$Rp_*(\Lambda_{V,X}) = p_*(\Lambda_{V,X}).$$

SGA 4 VIII 5.5 also gives the possibility of determining the fibres of the sheaf $p_*(\Lambda_{V,X})$, and, taking account of the fact that G acts freely on V, one finds

$$\big(p_*(\Lambda_{V,X})\big)_{\bar{y}} \simeq \begin{cases} \prod_{x \in p^{-1}(y)} \Lambda_{V,X,\bar{x}} \simeq \Lambda[G], & y \in p(V), \\ 0, & y \notin p(V), \end{cases}$$

where $\bar{y}$ is the geometric point of Y localized at y.

Consequently $p_*(\Lambda_{V,X})$ is flat over $\Lambda[G]$, fibre by fibre (SGA 4 XVII), and therefore is of finite Tor-dimension. Applying 2.1 to the canonical morphism $Y \to \mathrm{Spec}(k)$, we deduce that

$$R\Gamma_X(\Lambda_{V,X}) = R\Gamma_Y(Rp_*(\Lambda_{V,X}))$$

is of finite Tor-dimension.

To conclude that $R\Gamma_X(\Lambda_{V,X})$ is perfect, it remains to show that it is pseudo-coherent and has bounded cohomology (VIII 8.1). Since $\Lambda[G]$ is noetherian, to verify that $R\Gamma_X(\Lambda_{V,X})$ is pseudo-coherent it is enough to show that the groups $H^q(X, \Lambda_{V,X})$ are of finite type over $\Lambda[G]$ (VIII 7.2), or equivalently over Λ; this follows from (SGA 4 XIV 1.1), applied to the Λ-module $\Lambda_{V,X}$.

The Weil formula 6.1 will give an expression for the class $\mathrm{cl}_{K^\bullet(\Lambda[G])}(R\Gamma_X(\Lambda_{V,X}))$, when X is a curve, in terms of known global invariants and local invariants that we shall define in no. 5.

3. Reminders on linear representations of finite groups

In this number, Λ denotes a commutative ring, and G a group.

3.1. Characters

Consider the full subcategory $\mathcal{E}$ of $\mathrm{Mod}(\Lambda[G])$ consisting of $\Lambda[G]$-modules M whose underlying Λ-module is projective of finite type. For such a module M and for $g \in G$, consider the endomorphism, for the Λ-module structure,

$$g_M : M \longrightarrow M, \qquad g_M(x) = gx.$$

One obtains a function

$$\chi_M : G \longrightarrow \Lambda, \qquad \chi_M(g) = \mathrm{Tr}^*_\Lambda(g),$$

which is a central function on G and is called the character of the $\Lambda[G]$-module M.

Associating to each $M \in \mathrm{ob}(\mathcal{E})$ its character χ_M gives an additive function (VIII 1). Using the formalism of traces for endomorphisms of perfect complexes, one even obtains an additive function Tr on the category of complexes of $\Lambda[G]$-modules which are perfect as complexes of Λ-modules. Hence an homomorphism

$$\mathrm{Tr} : R^\bullet(G) \longrightarrow \mathcal{F}(G, \Lambda),$$

where $R^\bullet_\Lambda(G)$ is the ring of representations of G over Λ (VIII 10), and $\mathcal{F}(G, \Lambda)$ is the module of central functions $G \to \Lambda$.

When G is finite, the composite of the canonical homomorphism

$$K^\bullet(\Lambda[G]) \longrightarrow R^\bullet_\Lambda(G)$$

with Tr will be denoted by tr.

Recall the following result (IX th. 1, cor. 3).

Proposition 3.2. Let $\mathbb{Z}_\ell$ be the ring of ℓ-adic integers and let G be a finite group. Then the homomorphism

$$\mathrm{tr} : K^\bullet(\mathbb{Z}_\ell[G]) \longrightarrow \mathcal{F}(G, \mathbb{Z}_\ell)$$

is a monomorphism. Two projective $\mathbb{Z}_\ell[G]$-modules having the same trace function in $\mathcal{F}(G, \mathbb{Z}_\ell)$ are isomorphic.

3.3. Restriction and induction

Let $\alpha : G \to G'$ be a homomorphism from a group G to a group G'. By restriction of operators one obtains an exact functor

$$J : \mathrm{Mod}(\Lambda[G']) \longrightarrow \mathrm{Mod}(\Lambda[G]).$$

This functor has a left adjoint

$$I : \mathrm{Mod}(\Lambda[G]) \longrightarrow \mathrm{Mod}(\Lambda[G']),$$

namely

$$I(F) = \Lambda[G'] \otimes_{\Lambda[G]} F.$$

If F is projective of finite type, respectively of finite type, then so is $I(F)$.

If $\varphi \in \mathcal{F}(G', \Lambda)$ is a central function on G', the function $\varphi \circ \alpha$ is a central function on G, and therefore one obtains an application

$$\alpha^* : \mathcal{F}(G', \Lambda) \longrightarrow \mathcal{F}(G, \Lambda).$$

If φ is the character of a $\Lambda[G']$-module M in $\mathcal{C}(G')$, then $\alpha^*(\varphi)$ is the character of the $\Lambda[G]$-module $J(M)$.

Now suppose that $\alpha : G \to G'$ is injective and that G has finite index in G'. If F is a $\Lambda[G]$-module in $\mathcal{C}(G)$ whose character is $\psi : G \to \Lambda$, then $I(F)$ lies in $\mathcal{C}(G')$ and the character $\psi^* : G' \to \Lambda$ of $I(F)$ is the character induced by ψ, i.e. the function on G' deduced from ψ by the formula

$$\psi^*(g) = \sum_{t \in G'/G} \psi(t^{-1}gt), \tag{3.3.1}$$

with the convention that $\psi(t^{-1}gt) = 0$ if $t^{-1}gt \notin G$.

3.4. Additional structures on complexes

Let $X^\bullet$ and $Y^\bullet$ be two complexes of A-modules. As in the case of modules, if one of the complexes $X^\bullet$, $Y^\bullet$ has an additional structure of an A-B-bimodule, it is possible to introduce on $\mathrm{Hom}_A^\bullet(X^\bullet, Y^\bullet)$ a structure of complex of B-modules, and consequently a corresponding structure on $\mathrm{RHom}_A(X^\bullet, Y^\bullet)$.

For example, suppose that $X^\bullet$ is an object of $D^-(A)$ and that $Y^\bullet$ is a complex of A-B-bimodules; to be precise, suppose that we are in the case described by the symbol ${}_{A-B}Y^\bullet$. In particular, $Y^\bullet$ is an object of $D(A)$. Let $P^\bullet \to X^\bullet$ be a projective resolution of $X^\bullet$. Then $\mathrm{Hom}_A^\bullet(P^\bullet, Y^\bullet)$ is evidently a complex of left B-modules, i.e. an object of $D(B)$. If another projective resolution $P_1^\bullet \to X^\bullet$ is used, the complex of B-modules $\mathrm{Hom}_A^\bullet(P_1^\bullet, Y^\bullet)$ is canonically isomorphic in $D(B)$ to $\mathrm{Hom}_A^\bullet(P^\bullet, Y^\bullet)$. It follows that one may define $\mathrm{RHom}_A(X^\bullet, Y^\bullet)$ as an object of $D(B)$, determined up to unique isomorphism, and functorial in $X^\bullet$ in $D^-(A)$ and in $Y^\bullet$ in $D(A \otimes_{\mathbb{Z}} B)$.

Analogous considerations apply to the complex $X^\bullet \otimes_A^{\mathbf{L}} Y^\bullet$. For example, if $Y^\bullet$ is a complex of A-B-bimodules as above and $X^\bullet$ is a right-bounded complex of right A-modules, one may define $X^\bullet \otimes_A^{\mathbf{L}} Y^\bullet$ as an object of $D(B)$ determined up to unique isomorphism.

3.5

Let Λ be a commutative ring, let A and B be two algebras over Λ, and put $C = A \otimes_\Lambda B$. Thus C-modules are A-B-bimodules.

If Δ is a full triangulated subcategory of $D(A)$, denote by $D(C)_\Delta$ the full triangulated subcategory of $D(C)$ generated by the complexes which, when regarded as objects of $D(A)$, belong to Δ.

Proposition 3.6. With the notation of 3.4 and 3.5, let Δ be a full triangulated subcategory of $D(A)$ stable under direct factors. If $P^\bullet$ is an object of $D(B)_{\mathrm{parf}}$ (VIII 7) and $M^\bullet$ is an object of $D(C)_\Delta$, then the complex of A-modules $\mathrm{RHom}_B(P^\bullet, M^\bullet) \in D(A)$ defined in 4.1 is an object of Δ. In particular, there is a pairing of triangulated categories

$$\mathrm{RHom} : D(B)_{\mathrm{parf}} \times D(C)_\Delta \longrightarrow \Delta, \tag{3.6.1}$$

that is, a bifunctor exact in each variable, and consequently (VIII 3) a bilinear map

$$K^\bullet(B) \times K^\bullet(D(C)_\Delta) \xrightarrow{\mathrm{hom}} K(\Delta) \tag{3.6.2}$$

such that

$$K(a)(\mathrm{cl}_{K^\bullet(B)}(P^\bullet), \mathrm{cl}_{K(D(C)_\Delta)}(M^\bullet)) = \mathrm{cl}_{K(\Delta)}(\mathrm{RHom}_B(P^\bullet, M^\bullet)). \tag{3.6.3}$$

One obtains an analogous statement on replacing B by its opposite B° and $\mathrm{RHom}_B(P^\bullet, M^\bullet)$ by $P^\bullet \otimes^{\mathbf{L}}_B M^\bullet$.

Proof. First one proves that $\mathrm{RHom}_B(P^\bullet, M^\bullet)$ is an object of Δ in the special case where $P^\bullet$ has a single nonzero component, and then argues by induction on the number of nonzero components of $P^\bullet$.

3.7

Let P be a $\Lambda[G]$-module. It is in particular a Λ-module. The Λ-module $\check{P} = \mathrm{Hom}_\Lambda(P, \Lambda)$ can be endowed with a left $\Lambda[G]$-module structure by putting, for every $u \in \mathrm{Hom}_\Lambda(P, \Lambda)$ and $g \in G$, $(gu)(x) = u(g^{-1}x)$, i.e.

$$g_{\check{P}} = {}^t(g^{-1})_P. \tag{3.7.1}$$

The $\Lambda[G]$-module $\check{P}$ thus obtained is called the dual of P.

One may therefore define the dual $\check{P}^\bullet = \mathrm{Hom}^\bullet_\Lambda(P^\bullet, \Lambda)$ of a complex $P^\bullet$ of $\Lambda[G]$-modules as a complex of $\Lambda[G]$-modules.

If χ_P is the character of P, the character $\chi_{\check{P}}$ of its dual is given by

$$\chi_{\check{P}}(g) = \chi_P(g^{-1}), \tag{3.7.2}$$

which follows immediately from (4.3.1), using the formula

$$\mathrm{Tr}^*_\Lambda(v) = \mathrm{Tr}^*_\Lambda({}^t v).$$

If P is a projective $\Lambda[G]$-module of finite type, it is clear that $\check{P}$ is also a projective $\Lambda[G]$-module of finite type. Moreover, in this case the canonical homomorphism of Λ-modules

$$P \longrightarrow \check{\check{P}}$$

is in fact an isomorphism of $\Lambda[G]$-modules. In this way one defines on $K^\bullet(\Lambda[G])$ an involution

$$x \longmapsto \check{x},$$

which associates with the class of P the class of $\check{P}$. It is immediate that if $\mu : \Lambda \to \Gamma$ is a homomorphism of commutative rings and $u : \Lambda[G] \to \Gamma[G]$ the associated homomorphism, then the homomorphism

$$u^* : K^\bullet(\Lambda[G]) \longrightarrow K^\bullet(\Gamma[G])$$

commutes with the involutions $x \longmapsto \check{x}$ on $K^\bullet(\Lambda[G])$ and $K^\bullet(\Gamma[G])$.

Let A be an algebra over Λ, and put

$$A[G] = \Lambda[G] \otimes_\Lambda A.$$

Given a complex $X^\bullet$ of $A[G]$-modules, denote by $X^{\bullet G}$ the complex of A-modules which is the image of $X^\bullet$ under the functor that associates to each $A[G]$-module X the A-module formed by the elements of X invariant under G.

Proposition 3.8. Let G be a finite group, let $P^\bullet$ be a bounded complex of $\Lambda[G]$-modules all of whose components are projective of finite type, and let $M^\bullet$ be a complex of $A[G]$-modules. Under these conditions there are canonical isomorphisms of complexes of A-modules

$$\mathrm{Hom}^\bullet_{\Lambda[G]}(P^\bullet, M^\bullet) \simeq \mathrm{Hom}^\bullet_\Lambda(P^\bullet, M^\bullet)^G \simeq (\check{P}^\bullet \otimes_\Lambda M^\bullet)^G \simeq \check{P}^\bullet \otimes_{\Lambda[G]} M^\bullet. \tag{3.8.1}$$

The proof uses the well-known isomorphisms in the case of modules and is left to the reader. Note that, in the second and third terms, the operations of G on $\mathrm{Hom}^\bullet_\Lambda(P^\bullet, M^\bullet)$, respectively on $\check{P}^\bullet \otimes_\Lambda M^\bullet$, are defined by transport of structure from its operations on $P^\bullet$ and $M^\bullet$, respectively $\check{P}^\bullet$ and $\check{M}^\bullet$.

Corollary 3.9. If $P^\bullet \in \mathrm{ob}(D(\Lambda[G])_{\mathrm{parf}})$ and $M^\bullet \in D^+(A[G])$, then in the derived category $D(A)$ one has the following isomorphisms:

$$\mathrm{RHom}_{\Lambda[G]}(P^\bullet, M^\bullet) = R\Gamma^G(\check{P}^\bullet \otimes^{\mathbf{L}}_\Lambda M^\bullet) \simeq \check{P}^\bullet \otimes_{\Lambda[G]} M^\bullet. \tag{3.9.1}$$

Indeed, since $P^\bullet \in D(\Lambda[G])_{\mathrm{parf}}$, we may suppose that $P^\bullet$ is bounded and that all its components are projective of finite type. Hence

$$\mathrm{RHom}_{\Lambda[G]}(P^\bullet, M^\bullet) = \mathrm{Hom}^\bullet_{\Lambda[G]}(P^\bullet, M^\bullet)$$

and one can use the isomorphisms (4.3.4). But $\check{P}^\bullet$ is, like $P^\bullet$, bounded with projective finite-type components, hence

$$\check{P}^\bullet \otimes_{\Lambda[G]} M^\bullet \simeq \check{P}^\bullet \otimes^{\mathbf{L}}_{\Lambda[G]} M^\bullet.$$

Similarly, $\check{P}^\bullet \otimes_\Lambda M^\bullet = \check{P}^\bullet \otimes^{\mathbf{L}}_\Lambda M^\bullet$. Moreover the components of the complex $\check{P}^\bullet \otimes_\Lambda M^\bullet$ are cohomologically trivial ([3] IX 3), and therefore

$$R\Gamma^G(\check{P}^\bullet \otimes^{\mathbf{L}}_\Lambda M^\bullet) \simeq (\check{P}^\bullet \otimes_\Lambda M^\bullet)^G.$$

4. The Swan representation

Let E be a smooth connected algebraic curve over the algebraically closed field k. If $x \in E$ is a closed point of E, its local ring $\mathcal{O}_{E,x}$, or simply $\mathcal{O}_x$, is a discrete valuation ring whose field of fractions is isomorphic to the field of rational functions on E and whose residue field is k. The corresponding valuation will be denoted v_x.

Lemma 4.1. Let E be a smooth algebraic curve over the algebraically closed field k, and let $g : E \to E$ be an endomorphism of E different from the identity. Suppose that $x \in E$ is an isolated fixed point of g, and let π be a uniformizer of $\mathcal{O}_{E,x}$. If v_x is the corresponding valuation of $\mathcal{O}_{E,x}$, then the multiplicity $v_x(g)$ of the fixed point x of the map g (IV) is equal to $v_x(g(\pi) - \pi)$.

In the product $E \times E$, the diagonal and the graph of the endomorphism g will be denoted respectively by Δ and Γ_g. Let

$$\gamma : E \longrightarrow E \times E, \qquad \delta : E \longrightarrow E \times E$$

be the corresponding immersions. On the completed local rings at x and at (x, x), they are given by homomorphisms

$$\gamma^*, \delta^* : A \widehat{\otimes} A \longrightarrow A \qquad (A = \widehat{\mathcal{O}}_x),$$

where

$$\delta^*(a \otimes b) = ab, \qquad \gamma^*(a \otimes b) = a\, g^*(b).$$

We have to evaluate the multiplicity $v_x(g)$ of the point $\delta(x)$ in the intersection $\Delta\Gamma_g$ on $E \times E$. The divisor Δ corresponds to the ideal generated by the element $1 \otimes \pi - \pi \otimes 1$ of $A \widehat{\otimes} A$. Hence the multiplicity of $\delta(x)$ in the intersection $\Delta\Gamma_g$ is

$$v_x(g) = v_x(\gamma^*(1 \otimes \pi - \pi \otimes 1)) = v_x(g(\pi) - \pi),$$

as required.

4.2

Let C be a smooth, proper, connected algebraic curve over the algebraically closed field k. If η is its generic point, let $K = k(\eta)$ be its field of rational functions.

Let

$$K' \supset K, \qquad [K' : K] = n$$

be a finite Galois extension of degree n with Galois group G. Let C' be the normalization of C in K', and let

$$p : C' \longrightarrow C$$

be the canonical projection. The Galois group G acts naturally on C'. The stabilizer of $y' \in C'$ in G will be denoted by $G_{y'}$.

If π is a uniformizer of $\mathcal{O}_{C',y'}$ and if $s \in G_{y'}$, $s \neq e$, put

$$v_{y'}(s(\pi) - \pi) = v_{y'}(s) \tag{4.2.1}$$

(the multiplicity of the fixed point y' for the map $s : C' \to C'$ (Lemma 5.1)).

The Swan representation associated with y' is defined by its character $\sigma_{y'}$, given by

$$\sigma_{y'}(s) = \begin{cases} 1 - v_{y'}(s), & s \neq e, \\ \sum_{s \neq e} (v_{y'}(s) - 1), & s = e. \end{cases} \tag{4.2.2}$$

The results of Artin–Serre–Swan (IX Th. 4) show that, for a prime number ℓ distinct from the characteristic of k, there exists a projective $\mathbb{Z}_\ell[G_{y'}]$-module of finite type $Sw_{y'}$, determined up to isomorphism, whose character is $\sigma_{y'}$.

It is also useful to consider the $\mathbb{Z}_\ell[G_{y'}]$-module

$$Sw'_{y'} = Sw_{y'} \otimes \mathbb{Z}_\ell[G_{y'}]. \tag{4.2.3}$$

The character $\sigma'_{y'}$ of $Sw'_{y'}$ is given by

$$\sigma'_{y'}(s) = \begin{cases} 1 - v_{y'}(s), & s \neq e, \\ 1 + \sum_{s \neq e} v_{y'}(s) = 1 + v_{y'}(\mathfrak{D}_{C'/C}), & s = e, \end{cases} \tag{4.2.4}$$

where $\mathfrak{D}_{C'/C}$ is the different of the covering C'/C; the last formula is just [3, Chap. VI 2, prop. 4] with $H = \{1\}$.

Finally, the function

$$a_{y'} = \sigma_{y'} + u_{G_{y'}} = \sigma'_{y'} - 1_{G_{y'}}, \tag{4.2.5}$$

where $u_{G_{y'}}$ denotes the character of the augmentation ideal of $\mathbb{Z}_\ell[G_{y'}]$, is also the character of a $\mathbb{Q}_\ell[G_{y'}]$-module, the Artin representation of $G_{y'}$, which will be denoted by $Art_{y'}$.

Thus

$$a_{y'}(s) = \begin{cases} -v_{y'}(s), & s \neq e, \\ \sum_{s \neq e} v_{y'}(s) = v_{y'}(\mathfrak{D}_{C'/C}), & s = e. \end{cases} \tag{4.2.6}$$

Now consider the inclusion $G_{y'} \subset G$. We put

$$Sw_y = Sw_{y'} \otimes_{\mathbb{Z}_\ell[G_{y'}]} \mathbb{Z}_\ell[G], \qquad Sw'_y = Sw'_{y'} \otimes_{\mathbb{Z}_\ell[G_{y'}]} \mathbb{Z}_\ell[G], \tag{4.2.7}$$

$$Art_y = Art_{y'} \otimes_{\mathbb{Q}_\ell[G_{y'}]} \mathbb{Q}_\ell[G]. \tag{4.2.8}$$

The characters of the preceding representations are denoted by σ_y, σ'_y, and a_y.

4.3

The modules so obtained depend, up to isomorphism, only on the point $y \in C$, and not on the choice of the point y' and C' above y. Let y'' be another such point. There exists $g \in G$ such that $y'' = gy'$. The situation (C', y'', G) is deduced from the situation (C, y', G) by the isomorphism g on C' and by $\mathrm{int}(g) : h \mapsto ghg^{-1}$ on G. It follows by transport of structure that the modules Sw_y, etc., associated with y'' are deduced from those associated with y' by extension of the operators by means of $\mathrm{int}(g) : G \to G$. This extension is known to transform a module into an isomorphic module.

Proposition 4.4. With the notation of 3.7, with ($\Lambda = \mathbb{Z}_\ell$) and with $M^\bullet$ an object of $D^+(A[G])$, one has isomorphisms

$$(*) \qquad Sw_y \simeq \check{S}w_y,$$

$$(**) \qquad \mathrm{Hom}^\bullet_{\mathbb{Z}_\ell[G]}(Sw_y, M^\bullet) \simeq Sw_y \otimes_{\mathbb{Z}_\ell[G]} M^\bullet.$$

Proof. For two projective $\mathbb{Z}_\ell[G]$-modules of finite type to be isomorphic, it is enough that they have the same character (3.2). If $\check{\sigma}_y$ denotes the character of $\check{S}w_y$, then by (3.7.2)

$$\check{\sigma}_y(s) = \sigma_y(s^{-1}).$$

On the other hand

$$v_{y'}(s^{-1}(\pi) - \pi) = v_{y'}(s(s^{-1}(\pi) - \pi)) = v_{y'}(\pi - s(\pi)) = v_{y'}(s(\pi) - \pi),$$

so $Sw_{y'} \simeq \check{S}w_{y'}$, whence formula $(*)$ by definition (4.2.7). Formula $(**)$ follows from 3.8.

4.5

We shall need below an explicit formula for the character of the Swan representation. In fact one has the formulas

$$\sigma^*_{y'}(s) = \sigma^*_{y''}(s) = \sigma_y(s) = \begin{cases} \sum_{\substack{p(z')=y \\ s(z')=z'}} (1 - v_{z'}(s)), & s \neq e, \\ \sum_{p(z')=y} (1 + v_{z'}(\mathfrak{D}_{C'/C})) - n, & s = e, \end{cases} \tag{4.5.1}$$

$$\sigma'^*_{y'}(s) = \sigma'^*_{y''}(s) = \sigma'_y(s) = \begin{cases} \sum_{\substack{p(z')=y \\ s(z')=z'}} (1 - v_{z'}(s)), & s \neq e, \\ \sum_{p(z')=y} (1 + v_{z'}(\mathfrak{D}_{C'/C})), & s = e, \end{cases} \tag{4.5.2}$$

$$a^*_{y'}(s) = a^*_{y''}(s) = a_y(s) = \begin{cases} -\sum_{\substack{p(z')=y \\ s(z')=z'}} v_{z'}(s), & s \neq e, \\ \sum_{p(z')=y} v_{z'}(\mathfrak{D}_{C'/C}), & s = e. \end{cases} \tag{4.5.3}$$

To deduce these formulas one uses (3.3.1) and takes into account the following fact: if one fixes a point $y'_0 \in C'$, then for every $y' \in C'$ such that $p(y') = p(y'_0)$ one can find an element $g' \in G$ such that $g'(y') = y'_0$. The elements g' form a system of representatives for the right cosets of $G_{y'_0}$ in G, and moreover

$$G_{y'_0} = g' G_{y'} g'^{-1}.$$

This system of representatives can be used in the second member of formula (3.3.1), and one obtains the formulas displayed above.

4.6

The invariants Sw_y, Sw'_y, Art_y can be defined under more general conditions. Let C' be a smooth algebraic curve over k, not necessarily connected. Suppose that the finite group G acts on C' and that there exists an open subset U of $C = C'/G$, dense in C, such that $C'|U$ is a principal covering of U with group G. For a point $y \in C$, one can define the modules Sw_y, Sw'_y, Art_y by proceeding as above. One can reduce to the case where C' is connected in the following way. Let $y' \in C'$ be such that $p(y') = y$, let C'_1 be the irreducible component of C' containing y', and let C_1 be the irreducible component of C containing y. If $G_{C'_1}$ is the stabilizer of the component C'_1, and if η'_1 (resp. η_1) is the generic point of C'_1 (resp. C_1), then the extension

$$K'_1 = k(\eta'_1) \supset k(\eta_1) = K_1$$

is Galois with Galois group $G_{C'_1}$ and C'_1 is the normalization of C_1 in K'_1 (SGA 1 I 10). One can therefore apply the preceding considerations to the curves C'_1, C_1 and the group $G_{C'_1}$. In this way one obtains projective $\mathbb{Z}_\ell[G_{C'_1}]$-modules of finite type

$$Sw_{G_{C'_1},y}, \qquad Sw'_{G_{C'_1},y}, \qquad Art_{G_{C'_1},y},$$

and Sw_y, Sw'_y, Art_y are the induced modules associated with the inclusion $G_{C'_1} \subset G$.

Remark 4.6. The modules $Sw_{y'}$, $Sw'_{y'}$, $Art_{y'}$ are purely local invariants: they are known from the group $G_{y'}$ acting on the completion of the local ring $\mathcal{O}_{C',y'}$. Moreover $Sw_{y'} = 0$ if and only if $p : C' \to C$ is tamely ramified at y', or equivalently, if $G_{y'}$ has order prime to the characteristic of k [3 VI].

5. The Weil formula (compare [3 VI §4])

5.0

All schemes considered in this number will be defined over an algebraically closed base field k.

We shall use the following notation:

$$\Lambda_\nu = \mathbb{Z}/\ell^\nu\mathbb{Z},$$

where ℓ is a fixed prime number distinct from the characteristic of k.

Let $\mathbb{Z}_\ell \to \Lambda_\nu$ be the canonical homomorphism. It induces a homomorphism

$$\lambda_\nu : \mathbb{Z}_\ell[G] \longrightarrow \Lambda_\nu[G]$$

and consequently [VIII 9] a reduction homomorphism

$$\lambda^*_\nu : K^\bullet(\mathbb{Z}_\ell[G]) \longrightarrow K^\bullet(\Lambda_\nu[G]).$$

The images by λ^*_ν of the elements associated with the modules Sw_y, Sw'_y will be denoted by

$$Sw_y^{\Lambda_\nu}, \qquad Sw_y'^{\,\Lambda_\nu}.$$

The reduction homomorphism λ^*_ν is in fact an isomorphism [IX 1.5]. The inverse of λ^*_ν will be denoted by μ_ν.

The constant sheaf on the scheme X associated with the ring Λ_ν will be denoted by $\Lambda_{\nu,X}$.

Let V be an open subset of X, and let $j : V \hookrightarrow X$ be the canonical immersion. We put

$$j_!(\Lambda_{\nu,V}) = \Lambda_{\nu,V,X}.$$

Proposition 5.1. Let C' be a smooth proper algebraic curve over the algebraically closed field k, let G be a finite group acting on C', let $C = C'/G$, let $p : C' \to C$ be the canonical projection, let U be a dense open subset of C such that $U' = p^{-1}(U)$ is a principal covering of U with group G, let $Y = C - U$, let $Y' = p^{-1}(Y) = C' - U'$, and let $\mathrm{EP}(C)$ be the Euler–Poincaré characteristic of C (equal to $2 - 2g$ if C is connected of genus g). Under these conditions one has the Weil formula:

$$\mathrm{cl}_{K^\bullet(\Lambda_\nu[G])}(\mathrm{R}\Gamma_{C'}(\Lambda_{\nu,U',C'})) = \mathrm{EP}(C)\,\mathrm{cl}_{K^\bullet(\Lambda_\nu[G])}(\Lambda_\nu[G]) - \sum_{y\in Y} Sw'^{\Lambda_\nu}_y, \tag{5.2}$$

where the first member of (5.2) is defined using 2.1.

Proof. Denote by S_1 (resp. S_2) the first (resp. second) member of the formula to be proved. Since the reduction homomorphism λ_ν^* is in fact an isomorphism, it is enough to prove that

$$\mu_\nu(S_1) = \mu_\nu(S_2).$$

On the other hand, by (3.3.1), the trace homomorphism

$$K^\bullet(\mathbb{Z}_\ell[G]) \xrightarrow{tr} \mathcal{F}(G, \mathbb{Z}_\ell)$$

is a monomorphism. Consequently, it is enough to prove that

$$\mathrm{tr}(\mu_\nu(S_1)) = \mathrm{tr}(\mu_\nu(S_2)).$$

The character $\sigma_2 = \mathrm{tr}(\mu_\nu(S_2))$ is plainly given by

$$\sigma_2 = \mathrm{EP}(C) r_G - \sum_{y\in Y} \sigma'_y, \tag{5.2.1}$$

where σ'_y is the character of Sw'_y ((4.2.7) and (4.2.3)), and r_G is the regular representation.

Now consider the reduction homomorphisms for traces:

$$\mathcal{F}(G, \mathbb{Z}_\ell) \xrightarrow{\lambda_n^*} \mathcal{F}(G, \mathbb{Z}/\ell^n\mathbb{Z}).$$

One plainly has

$$\mathcal{F}(G, \mathbb{Z}_\ell) = \varprojlim_n \mathcal{F}(G, \mathbb{Z}/\ell^n\mathbb{Z}).$$

It is therefore enough to prove, for every n, that

$$\lambda_n^*(\mathrm{tr}(\mu_\nu(S_1))) = \lambda_n^*(\sigma_2).$$

The first member is equal to $\mathrm{tr}(\lambda_n^*(\mu_\nu(S_1)))$, while

$$\lambda_n^*(\mu_\nu(S_1)) = \mathrm{cl}_{K^\bullet(\Lambda_n[G])}(\mathrm{R}\Gamma_{C'}(\Lambda_{n,U',C'})),$$

by the Künneth formula (SGA 4 XVIII)

$$\mathrm{R}\Gamma_{C'}(\Lambda_{n,U',C'}) \otimes^L_{\Lambda_n} \Lambda_\nu \simeq \mathrm{R}\Gamma_{C'}(\Lambda_{\nu,U',C'}) \quad \text{for } n \geq \nu.$$

Thus we are reduced to proving the equality

$$\mathrm{tr}\big(\mathrm{cl}_{K^\bullet(\Lambda_n[G])}(\mathrm{R}\Gamma_{C'}(\Lambda_{n,U',C'}))\big) = \lambda_n^*(\sigma_2).$$

Let τ denote the first member of this equality, and let $g \in G$. The element g plainly induces an endomorphism of the distinguished triangle

$$\begin{array}{ccc} & \mathrm{R}\Gamma_{Y'}(\Lambda_{n,Y'}) & \\ \swarrow & & \searrow \\ \mathrm{R}\Gamma_{C'}(\Lambda_{n,U',C'}) & \longrightarrow & \mathrm{R}\Gamma_{C'}(\Lambda_{n,C'}) \end{array}$$

Therefore

$$\tau(g) = \mathrm{Tr}^*\, g_{\mathrm{R}\Gamma_{C'}(\Lambda_{n,U',C'})} = \mathrm{Tr}^*\, g_{\mathrm{R}\Gamma_{C'}(\Lambda_{n,C'})} - \mathrm{Tr}^*\, g_{\mathrm{R}\Gamma_{Y'}(\Lambda_{n,Y'})}.$$

For brevity, Tr^* has been written instead of $\mathrm{Tr}^*_{\Lambda_n}$.

Applying a trivial Lefschetz formula to the discrete space Y' on which g acts gives

$$\begin{aligned} \mathrm{Tr}^*\, g_{\mathrm{R}\Gamma_{Y'}(\Lambda_{n,Y'})} &= \text{the number of fixed points of the restriction } g_{Y'} \text{ of } g \text{ to } Y' \\ &= \sum_{\substack{y' \in Y' \\ gy' = y'}} 1. \end{aligned}$$

On the other hand, the Lefschetz formula (III 4.7) for g acting on C' gives, if $g \neq e$,

$$\mathrm{Tr}^*\, g_{\mathrm{R}\Gamma_{C'}(\Lambda_{n,C'})} = \sum_{y' \in Y'} v_{y'}(g),$$

the sum of the multiplicities of the fixed points of the map $g_{C'} : C' \to C'$. Also

$$\mathrm{Tr}^*\, g_{\mathrm{R}\Gamma_{C'}(\Lambda_{n,C'})} = \mathrm{EP}(C') \cdot 1_\Lambda \quad \text{for } g = e,$$

by the explicit computation of $H^1(C', \Lambda_{n,C'})$, via (SGA 4 IX 47) and Künneth (SGA 4 XVII). We therefore obtain the following formula for τ:

$$\tau(g) = \begin{cases} \displaystyle\sum_{\substack{y' \in Y' \\ g(y') = y'}} (v_{y'}(g) - 1), & g \neq e, \\ \mathrm{EP}(C') - \mathrm{card}(Y'), & g = e. \end{cases} \tag{5.2.2}$$

Comparison with (5.2.1) gives easily $\tau = \lambda_n^*(\sigma_2)$. Indeed, if $g \neq e$, the equality between $\tau(g)$ and $\lambda_n^*(\sigma_2)$ is immediate from (4.5.2). If $g = e$, the formula to be checked is

$$\mathrm{EP}(C') - \mathrm{card}(Y') = N\,\mathrm{EP}(C) - \sum_{y \in Y} \sigma'_y(e), \qquad N = \mathrm{card}(G),$$

that is, by (4.5.2),

$$\mathrm{EP}(C') - N\,\mathrm{EP}(C) = -\deg(\mathfrak{D}_{C'/C}),$$

which is nothing other than the classical Hurwitz formula.

6. Definition of the local terms $\varepsilon_x^{\Delta}(F)$

6.1

Let C be a connected smooth algebraic curve over the algebraically closed field k, let A be a Λ-algebra ($\Lambda = \mathbb{Z}/\ell^{\nu}\mathbb{Z}$, with ℓ distinct from the characteristic of k), and let $\Delta \subset D^+(A)$ be a triangulated subcategory of $D^+(A)$ stable under direct factors. Let F be a complex of sheaves of A-modules on C satisfying the following conditions:

i) For every geometric point $\bar{x} \in C(k)$, one has $F_{\bar{x}} \in \mathrm{ob}(\Delta)$.

ii) There exists a non-empty open subset of C on which F is locally constant; equivalently, there exist a non-empty open subset U of C and a connected Galois covering $C' \xrightarrow{p} C$ of C, with group G, such that, if $F' = p^*(F)$ is the inverse image of F by p, then $F'|U'$ is constant ($U' = p^{-1}(U)$).

The sheaf $F'|U'$ is therefore defined by a complex M of A-modules on which G acts. If η (resp. η') denotes the generic point of C (resp. C'), and if $\bar{\eta}$ (resp. $\bar{\eta}'$) is a geometric point above η (resp. η'), then

$$p(\eta') = \eta, \qquad F_{\bar{\eta}} \simeq F'_{\bar{\eta}'} = M. \tag{6.1.1}$$

As a complex of A-modules, M is isomorphic to $F_{\bar{\eta}}$ and, by condition i), is an object of Δ. Hence, by (3.6), for every $x \in C(k)$,

$$\mathrm{Hom}^{\bullet}_{\Lambda[G]}(Sw_x^{\Lambda}, M)$$

is an object of Δ, and so defines an element of $K(\Delta)$.

In fact the object of Δ defined by $\mathrm{Hom}^{\bullet}_{\Lambda[G]}(Sw_x^{\Lambda}, M)$ is independent, up to isomorphism, of the Galois covering $C' \to C$ which trivializes $F|U$. To show this it is enough to compare the elements associated with two coverings

$$C' \xrightarrow{p} C, \qquad C'' \xrightarrow{p'} C' \xrightarrow{p} C.$$

In this case, if G' is the Galois group of the covering $C'' \xrightarrow{p''} C$, then G is a quotient group of G'. Let

$$\varphi : \mathbb{Z}_{\ell}[G'] \longrightarrow \mathbb{Z}_{\ell}[G]$$

be the associated canonical epimorphism. The Swan modules are then related by

$$Sw_{G,x} \simeq Sw_{G',x} \otimes_{\mathbb{Z}_{\ell}[G']} \mathbb{Z}_{\ell}[G],$$

which follows immediately from the fact that the character $a_{G,x}$ is the character induced from G' to G ([3] VI Prop. 3).

On the other hand, there is an isomorphism of complexes of $A[G']$-modules

$$F_{\bar{\eta}''} \simeq [F_{\bar{\eta}'}]_{(\varphi)}.$$

It follows that there is a canonical isomorphism of complexes of A-modules between

$$\mathrm{Hom}^{\bullet}_{\Lambda[G]}(Sw^{\Lambda}_{G,x}, F_{\bar{\eta}}) \quad \text{and} \quad \mathrm{Hom}^{\bullet}_{\Lambda[G']}(Sw^{\Lambda}_{G',x}, F_{\bar{\eta}''})$$

(the adjunction formula).

6.2

We shall use the following notation:

$$\alpha_x^{\Delta}(F) = \mathrm{cl}_{K(\Delta)}(\mathrm{Hom}^{\bullet}_{\Lambda[G]}(Sw_x^{\Lambda}, F_{\bar{\eta}})), \tag{6.2.1}$$

$$\varepsilon_x^{\Delta}(F) = \alpha_x^{\Delta}(F) + (\mathrm{cl}_{K(\Delta)}(F_{\bar{\eta}}) - \mathrm{cl}_{K(\Delta)}(F_x)). \tag{6.2.2}$$

Of course, in formula (6.2.1), $F_{\bar{\eta}}$ is endowed with its $A[G]$-module structure by the isomorphism (6.1.1). Note that if $x \in C(k)$ is such that C' is tamely ramified at x, then by (4.6) $Sw_x = 0$, hence $\alpha_x^{\Delta}(F) = 0$, and in this case, in conformity with Ogg-Shafarevich, one has

$$\varepsilon_x^{\Delta}(F) = \mathrm{cl}_{K(\Delta)}(F_{\bar{\eta}}) - \mathrm{cl}_{K(\Delta)}(F_x). \tag{6.2.3}$$

It is clear that $\varepsilon_x^{\Delta}(F) = 0$ if $x \notin Y = C - U$, and therefore only finitely many x satisfy $\varepsilon_x^{\Delta}(F) \neq 0$.

We now give examples of categories Δ and complexes of sheaves F for which the conditions above are satisfied.

a) Let $\Delta = D^b(A)_{\mathrm{coh}}$ (VIII 5), and let F be a constructible complex of sheaves of A-modules (SGA 4 XVII) with bounded cohomology. In this case $\varepsilon_x^{\Delta}(F) \in K_{\bullet}(A)$.

b) Take $\Delta = D(A)_{\mathrm{parf}}$ (VIII 6), and let F be a constructible complex of sheaves of A-modules of finite tor-dimension. In this case $\varepsilon_x^{\Delta}(F) \in K^{\bullet}(A)$.

c) Let A, B be two Λ-algebras and let $\varphi : A \to B$ be a homomorphism of Λ-algebras. Take $\Delta = D^b(B \,\mathrm{rel}\, A)_{\mathrm{coh}}$ (VIII 10), and let F be a complex of sheaves of B-modules, constructible as a sheaf of complexes of A-modules and with bounded cohomology. One obtains $\varepsilon_x^{\Delta}(F) \in K_{\bullet}(B \,\mathrm{rel}\, A)$. Of course, one can vary this as above to obtain, for example, elements $\varepsilon_x^{\Delta}(F) \in K^{\bullet}(B \,\mathrm{rel}\, A)$.

7. Euler–Poincaré formula

Theorem 7.1. Let C be a connected, smooth, proper algebraic curve over the algebraically closed field k, let η be the generic point of C, let $\Delta \subset D^+(A)$ be a triangulated subcategory of $D^+(A)$ stable under direct factors, and let F be a complex of sheaves of A-modules satisfying conditions i), ii) of 7.1. Under these conditions one has $\mathrm{R}\Gamma_C(F) \in \mathrm{ob}(\Delta)$, and the following formula (Euler–Poincaré formula) is true:

$$\mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_C(F)) = \mathrm{EP}(C)\,\mathrm{cl}_{K(\Delta)}(F_{\bar{\eta}}) - \sum_{x \in C(k)} \varepsilon_x^{\Delta}(F), \tag{7.2}$$

where the $\varepsilon_x^{\Delta}(F)$ are defined in 6.2 (formula 6.2.2).

The proof of this theorem will be made in a few steps.

a) Let Ψ be a bounded below complex of sheaves of $\Lambda[G]$-modules on C. There is an isomorphism

$$R\Gamma^G(\mathrm{R}\Gamma_C(\Psi)) \simeq \mathrm{R}\Gamma_C(R\underline{\Gamma}^G(\Psi)), \tag{7.3}$$

where $\underline{\Gamma}^G$ is the functor "subsheaf of G-invariant sections." Indeed, Γ_C sends an injective sheaf of $\Lambda[G]$-modules to an injective $\Lambda[G]$-module, and $\underline{\Gamma}^G$ sends an injective sheaf of $\Lambda[G]$-modules to an injective sheaf of Λ-modules (using, for example, the evident adjoints of Γ_C and $\underline{\Gamma}^G$). Moreover

$$\Gamma^G \circ \Gamma_C = \Gamma_C \circ \underline{\Gamma}^G.$$

Taking derived functors on both sides and applying [5] prop. 3.1) gives (7.3).

b) Let Φ be a bounded below complex of sheaves of Λ-modules on C, zero outside U. There is an isomorphism

$$\Phi \simeq R\underline{\Gamma}^G(p_*(\Phi')), \qquad \Phi' = p^*(\Phi). \tag{7.4}$$

First note that the functors p^* and $\underline{\Gamma}^G \circ p_*$ establish quasi-inverse equivalences between the category of sheaves of Λ-modules on C' on which G acts and which are zero outside $U' = p^{-1}(U)$, and the category of sheaves of Λ-modules on C which are zero outside U. Hence one has the isomorphism

$$\Phi \simeq R((\underline{\Gamma}^G \circ p_*) \circ p^*)(\Phi).$$

On the other hand, one can again apply [5] Prop. 3.1), which gives, since $Rp^* = p^*$ and $Rp_* = p_*$:

$$\Phi \simeq R(\underline{\Gamma}^G \circ p_*)(p^*(\Phi)) \simeq (R\underline{\Gamma}^G)(p_*p^*(\Phi)),$$

which is the desired isomorphism.

c) Let Φ be a complex of sheaves as in b). One has the isomorphism

$$\mathrm{R}\Gamma_C(\Phi) = (R\Gamma^G)(\mathrm{R}\Gamma_{C'}(\Phi')), \qquad \Phi' = p^*(\Phi). \tag{7.5}$$

Indeed,

$$(R\Gamma^G)(\mathrm{R}\Gamma_{C'}(\Phi')) \simeq (R\Gamma^G)(\mathrm{R}\Gamma_C(p_*(\Phi'))) \simeq \mathrm{R}\Gamma_C(R\underline{\Gamma}^G(p_*(\Phi')))$$

by (7.3), and (7.5) follows from the isomorphism (7.4).

d) Let $i' : U' \to C'$, $i : U \to C$ be the canonical inclusions and put

$$\Phi = F_{U,C} = i_!(F|U).$$

To compute $\mathrm{R}\Gamma_C(\Phi)$, one may apply formula (7.5). On the other hand, with the notation of 7.1,

$$\Phi' \simeq \Lambda_{U',C'} \otimes^L_\Lambda M,$$

and the Künneth formula (SGA 4 XVII) gives

$$\mathrm{R}\Gamma_{C'}(\Phi') \simeq \mathrm{R}\Gamma_{C'}(\Lambda_{U',C'} \otimes^L_\Lambda M) \xleftarrow{\sim} \mathrm{R}\Gamma_{C'}(\Lambda_{U',C'}) \otimes^L_\Lambda M. \tag{7.6}$$

This last isomorphism is in fact an isomorphism between the objects of $D(A[G])$ defined by the two sides. Combining (7.6), (7.5), and formula (3.9.1), which is applicable by 2.1, one obtains

$$\mathrm{R}\Gamma_C(F_{U,C}) \simeq R\Gamma^G(\mathrm{R}\Gamma_{C'}(\Lambda_{U',C'}) \otimes^L_\Lambda M) \simeq \mathrm{RHom}_{\Lambda[G]}(\mathrm{R}\Gamma_{C'}(\Lambda_{U',C'})^\vee, M). \tag{7.7}$$

Thus, since $M \simeq F_{\bar\eta} \in \mathrm{ob}(\Delta)$ (condition (i)) and by (3.6), we find

$$\mathrm{R}\Gamma_C(F_{U,C}) \in \mathrm{ob}(\Delta).$$

On the other hand, there is the distinguished triangle (where $Y = C - U$)

$$\begin{array}{ccc} & \mathrm{R}\Gamma_Y(F|Y) & \\ \swarrow & & \nwarrow \\ \mathrm{R}\Gamma_C(F_{U,C}) & \longrightarrow & \mathrm{R}\Gamma_C(F) \end{array} \tag{7.8}$$

where obviously

$$\mathrm{R}\Gamma_Y(F) = \coprod_{y\in Y} F_y \in \mathrm{ob}(\Delta),$$

because $F_y \in \mathrm{ob}(\Delta)$ (condition (i)). It follows that $\mathrm{R}\Gamma_C(F) \in \mathrm{ob}(\Delta)$, which is the first assertion of the theorem. The distinguished triangle (7.8) furthermore gives the relation

$$\mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_C(F)) = \mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_C(F_{U,C})) + \sum_{y\in Y} \mathrm{cl}_{K(\Delta)}(F_y),$$

and, using the isomorphism 7.7,

$$\mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_C(F)) = \mathrm{cl}_{K(\Delta)}(\mathrm{RHom}_{\Lambda[G]}(\mathrm{R}\Gamma_{C'}(\Lambda_{U',C'})^\vee, F_{\bar\eta})) + \sum_{y\in Y} \mathrm{cl}_{K(\Delta)}(F_y).$$

To obtain the Euler–Poincaré formula it remains only to use the Weil formula (5.2). Indeed, first 4.4, (5.2), and 3.6 (in the particular case $B = \Lambda[G]$) give

$$\mathrm{cl}_{K^\bullet(\Lambda[G])}(\mathrm{R}\Gamma_{C'}(\Lambda_{U',C'})) = \mathrm{cl}_{K^\bullet(\Lambda[G])}(\mathrm{R}\Gamma_{C'}(\Lambda_{U',C'})^\vee).$$

$$\begin{aligned}
\mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_C(F)) &= \hom\Big(\mathrm{cl}_{K^\bullet(\Lambda[G])}(\mathrm{R}\Gamma_{C'}(\Lambda_{U',C'})), \mathrm{cl}_{K(D(A[G])_\Delta)}(F_{\bar\eta})\Big) + \sum_{y\in Y} \mathrm{cl}_{K(\Delta)}(F_y) \\
&= \sum_{y\in Y} \mathrm{cl}_{K(\Delta)}(F_y) \\
&\quad + \hom\Big(\mathrm{EP}(C)\,\mathrm{cl}_{K^\bullet(\Lambda[G])}(\Lambda[G]) - \sum_{y\in Y}(Sw_y^\Lambda + \mathrm{cl}_{K^\bullet(\Lambda[G])}(\Lambda[G])), \\
&\qquad\qquad \mathrm{cl}_{K(D(A[G])_\Delta)}(F_{\bar\eta})\Big) \\
&= \sum_{y\in Y} \mathrm{cl}_{K(\Delta)}(F_y) + \mathrm{EP}(C)\,\mathrm{cl}_{K(\Delta)}(F_{\bar\eta}) - \sum_{y\in Y}(\alpha_y^\Delta(F) + \mathrm{cl}_{K(\Delta)}(F_{\bar\eta})) \\
&= \mathrm{EP}(C)\,\mathrm{cl}_{K(\Delta)}(F_{\bar\eta}) - \sum_{y\in Y} \varepsilon_y^\Delta(F).
\end{aligned}$$

Since $\varepsilon_x^\Delta(F) = 0$ for $x \notin Y$, this is exactly formula (7.2). For a complex of sheaves F satisfying the conditions of 7.1, we introduce the notation

$$\mathrm{EP}_\Delta(C, F) = \mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_C(F)).$$

Corollary 7.9. If F, F' are complexes of sheaves satisfying the conditions of 7.1 and if they are locally isomorphic (for the étale topology) as complexes of A-modules, then

$$\mathrm{EP}_\Delta(C, F) = \mathrm{EP}_\Delta(C, F'). \tag{7.10}$$

In particular, if F is locally constant of value $M^\bullet$, then

$$\mathrm{EP}_\Delta(C, F) = \mathrm{EP}(C)\,\mathrm{cl}_{K(\Delta)}(M^\bullet). \tag{7.11}$$

Corollary 7.12. Let C be a connected smooth proper algebraic curve over k, let V be a non-empty open subset of C, let Δ be a subcategory of $D^+(A)$ as in 7.1, and let F be a complex of sheaves of A-modules on V such that its restriction to a suitable non-empty open subset of V is trivialized by

a Galois covering of V. Suppose moreover that $F_{\bar{x}} \in \mathrm{ob}(\Delta)$ for every $x \in V$. Under these conditions one has

$$(*) \qquad \mathrm{R}\Gamma_! V(F),\ \mathrm{R}\Gamma_V(F) \in \mathrm{ob}(\Delta),$$

$$(**) \qquad \mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_! V(F)) = \mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_V(F)).$$

Put $\mathrm{EP}_\Delta(V,F) = \mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_V(F))$ and

$$\mathrm{EP}(V) = \mathrm{EP}_{D(F_\ell)_{\mathrm{coh}}}(V, F_\ell) = \mathrm{EP}(C) - \mathrm{card}(Z),$$

where $Z = C - V$ and where F_ℓ is the sheaf on C defined in dimension zero by the constant sheaf associated with $F_\ell = \mathbb{Z}/\ell\mathbb{Z}$. Then one has the formula

$$\mathrm{EP}_\Delta(V,F) = \mathrm{EP}(V)\,\mathrm{cl}_{K(\Delta)}(F_{\bar{\eta}}) - \sum_{x \in V(k)} \varepsilon_x^\Delta(F) - \sum_{x \in Z} \alpha_x^\Delta(F), \tag{7.13}$$

where ε_x^Δ and α_x^Δ are defined by (6.2.1), (6.2.2).

We shall use the following lemma.

Lemma 7.14. Let K be the field of fractions of a strictly local discrete valuation ring R, let $W = \mathrm{Spec}\, K$, let A be a noetherian ring annihilated by an integer n prime to the residual characteristic p of R, and let F be a complex of sheaves of A-modules on W trivialized by a finite extension of K. If Δ is a triangulated subcategory of $D^+(A)$ stable under direct factors and if $F_{\bar{\eta}} \in \mathrm{ob}(\Delta)$ (η the generic point of S), then $\mathrm{R}\Gamma_W(F) \in \mathrm{ob}(\Delta)$ and

$$\mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_W(F)) = 0.$$

Proof of 7.14. Let π be the fundamental group of W. Then F corresponds to a complex of A-modules $M^\bullet$ with π as group of operators. The underlying complex of A-modules of $M^\bullet$ is isomorphic to $F_{\bar{\eta}}$ and consequently belongs to $\mathrm{ob}(\Delta)$. Introduce the quotient group $\bar{\pi}$ of π by its unique Sylow p-subgroup P [4, II 33], that is, the projective limit of discrete quotient groups of π which are of order prime to p, where p is the characteristic exponent of the residue field of R (if $p = 1$, put $\bar{\pi} = \pi$). Thus there is an exact sequence

$$1 \longrightarrow P \longrightarrow \pi \longrightarrow \bar{\pi} \longrightarrow 0,$$

and one obtains

$$\mathrm{R}\Gamma_W(F) \simeq R\Gamma^\pi(M^\bullet) \simeq R\Gamma^{\bar{\pi}}(R\Gamma^P(M^\bullet))$$

(Hochschild–Serre isomorphism). Now P acts on $M^\bullet$ through a finite quotient group, which is therefore a p-group, hence of order prime to n. Thus

$$R\Gamma^P(M^\bullet) \simeq \Gamma^P(M^\bullet),$$

and $\Gamma^P(M^\bullet)$ is a direct factor of $M^\bullet$, hence belongs to $\mathrm{ob}(\Delta)$. On the other hand

$$\bar{\pi} = \prod_{\ell \neq p} \mathbb{Z}_\ell$$

([4], II 33). We are therefore reduced to proving that if $M^\bullet \in \mathrm{ob}(\Delta)$, then $R\Gamma^{\bar{\pi}}(M^\bullet) \in \mathrm{ob}(\Delta)$ and

$$\mathrm{cl}_{K(\Delta)}(R\Gamma^{\bar{\pi}}(M^\bullet)) = 0.$$

For this, let f be a topological generator of $\bar{\pi}$. We may suppose that the components M^i of M are $\bar{\pi}$-modules such that

$$H^j(\bar{\pi}, M^i) = 0 \quad \text{if } j \geq 1.$$

There is then a distinguished triangle

$$\begin{array}{ccc} & M^\bullet & \\ {\scriptstyle 1-f}\swarrow & & \nwarrow \\ R\Gamma^{\bar{\pi}}(M^\bullet) & \longrightarrow & M^\bullet \end{array} \tag{7.15}$$

Indeed, on the one hand it is clear that $R\Gamma^{\bar{\pi}} = \mathrm{Ker}(1-f)$. On the other hand $1-f : M^\bullet \to M^\bullet$ is surjective. Indeed

$$H^1(\bar{\pi}, M) = M^\bullet/(1-f)M^\bullet$$

(see for this calculation [4] pp. 197, in a substantially analogous case), and therefore $M^\bullet = (1-f)M^\bullet$. The triangle (7.15) gives at the same time $R\Gamma^{\bar{\pi}}(M^\bullet) \in \mathrm{ob}(\Delta)$ and

$$\mathrm{cl}_{K(\Delta)}(R\Gamma^{\bar{\pi}}(M^\bullet)) = 0,$$

which proves 7.14.

Proof of 7.12. The fact that $\mathrm{R}\Gamma_! V(F) \in \mathrm{ob}(\Delta)$ follows immediately from 7.1 applied to the complex $i_!(F)$, where $i : V \to C$; indeed

$$\mathrm{R}\Gamma_! V(F) = \mathrm{R}\Gamma_C(i_! F).$$

To prove that $\mathrm{R}\Gamma_V(F) \in \mathrm{ob}(\Delta)$, consider the distinguished triangle

$$\begin{array}{ccc} & Q^\bullet & \\ \swarrow & & \nwarrow \\ Ri_!(F) & \longrightarrow & Ri_*(F), \end{array}$$

where $Q^\bullet$ is concentrated on $Z = C - V$. Applying $\mathrm{R}\Gamma_C$ gives the distinguished triangle

$$\begin{array}{ccc} & \mathrm{R}\Gamma_Z(Q^\bullet|Z) & \\ \swarrow & & \nwarrow \\ \mathrm{R}\Gamma_! V(F) & \longrightarrow & \mathrm{R}\Gamma_V(F). \end{array} \tag{7.16}$$

Since $\mathrm{R}\Gamma_! V(F) \in \mathrm{ob}(\Delta)$, it follows that $\mathrm{R}\Gamma_V(F) \in \mathrm{ob}(\Delta)$ if and only if $\mathrm{R}\Gamma_Z(Q^\bullet|Z) \in \mathrm{ob}(\Delta)$, that is, if and only if $(Ri_*(F))_{\bar{x}} \in \mathrm{ob}(\Delta)$ for every $x \in Z$. Recall that to calculate $(Ri_*(F))_{\bar{x}}$, one considers the cartesian square

$$\begin{array}{ccc} \bar{V} & \overset{j}{\hookrightarrow} & C_x \\ {\scriptstyle u}\downarrow & & \downarrow \\ V & \hookrightarrow & C \end{array}$$

where C_x is the strictly localized scheme corresponding to the geometric point x. One has

$$Ri_*(F)_{\bar{x}} \simeq \mathrm{R}\Gamma_{\bar{V}}(u^*(F)),$$

by virtue of 7.14, and therefore $(Ri_*(F))_{\bar{x}} \in \mathrm{ob}(\Delta)$ and

$$\mathrm{cl}_{K(\Delta)}((Ri_*(F))_{\bar{x}}) = 0.$$

It follows that

$$\mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_Z(Q^\bullet|Z)) = 0,$$

and the distinguished triangle (7.16) gives

$$\mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_! V(F)) = \mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_V(F)).$$

Finally, to establish (7.13), it is enough to use the Euler–Poincaré formula (7.2) for the complex of sheaves $i_!(F)$:

$$\mathrm{EP}_\Delta(V,F) = \mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_! V(F)) = \mathrm{cl}_{K(\Delta)}(\mathrm{R}\Gamma_C(i_!(F))) = \mathrm{EP}(C)\,\mathrm{cl}_{K(\Delta)}(F_{\bar{\eta}}) - \sum_{x\in C(k)} \varepsilon_x^\Delta(i_!(F)).$$

But

$$\sum_{x\in C(k)} \varepsilon_x^\Delta(i_!(F)) = \sum_{x\in V(k)} \varepsilon_x^\Delta(F) + \sum_{x\in Z} \varepsilon_x^\Delta(F).$$

For $x \in Z$ one has $(i_!(F))_{\bar{x}} = 0$, and consequently, for such x,

$$\varepsilon_x^\Delta(i_!(F)) = \alpha_x^\Delta(F) + \mathrm{cl}_{K(\Delta)}(F_{\bar{\eta}}),$$

which gives formula (7.13).

NIELSEN–WECKEN AND LEFSCHETZ FORMULAS IN ALGEBRAIC GEOMETRY

by A. Grothendieck

written up by I. BUCUR

1.

Let X' be a scheme proper over the algebraically closed field k, and let G be a finite group acting on X'.

For each element $g \in G$, denote by

$$g_{X'} : X' \to X'$$

the automorphism of X' induced by g.

Suppose that there exists an open subset U' of X', stable under G, such that G acts freely on U', and let

$$\Lambda_n = \mathbb{Z}/\ell^n\mathbb{Z},$$

where ℓ is a prime number different from the characteristic of k.

Let $\Lambda_{n,U',X'}$ denote the sheaf $i_!(\Lambda_{n,U'})$ on X', where $\Lambda_{n,U'}$ is the constant sheaf on U' associated with the ring Λ_n and where $i : U' \hookrightarrow X'$ is the canonical immersion of U' into X'. The sheaf $\Lambda_{n,U',X'}$ is endowed in a natural way with the structure of a sheaf with group G of operators. Consequently the complex

$$H_{n,U',X'} = R\Gamma_{X'}(\Lambda_{n,U',X'})$$

is a complex of $\Lambda_n[G]$-modules, and more precisely a perfect complex (VIII, 7) of $\Lambda_n[G]$-modules (IX, 2).

We shall see below that it is more convenient for our purpose to consider, instead of the complex $R\Gamma_{X'}(\Lambda_{n,U',X'})$, its dual

$$H^\vee_{n,U',X'} = R\Gamma_{X'}(\Lambda_{n,U',X'})^\vee$$

with respect to the ring Λ_n, in the sense of derived categories:

$$H^\vee_{n,U',X'} = R\Gamma_{X'}(\Lambda_{n,U',X'})^\vee = R\operatorname{Hom}_{\Lambda_n}(R\Gamma_{X'}(\Lambda_{n,U',X'}), \Lambda_n).$$

The complex $R\Gamma_{X'}(\Lambda_{n,U',X'})^\vee$ is a perfect complex of $\Lambda_n[G]$-modules.

Suppose now that an endomorphism $f' : X' \to X'$ of the scheme X' and an endomorphism $\varphi : G \to G$ of the group G are given, satisfying the following two conditions:

$$f' g_{X'} = \varphi(g)_{X'} f' \qquad \forall g \in G. \tag{1.1}$$

$$\text{The complement } Y' = X' - U' \text{ is stable under } f'. \tag{1.2}$$

Under the hypotheses already made, Y' is stable under G. In general one does not require the open subset U' to be stable under f'.

We therefore obtain homomorphisms of sheaves

$$f'_{\Lambda_{n,X'}} : \Lambda_{n,X'} \longrightarrow \Lambda_{n,X'}, \qquad f'_{\Lambda_{n,Y'}} : \Lambda_{n,Y'} \longrightarrow \Lambda_{n,Y'},$$
$$f'_{\Lambda_{n,U',X'}} : \Lambda_{n,U',X'} \longrightarrow \Lambda_{n,U',X'}, \qquad g_{\Lambda_{n,U',X'}} : \Lambda_{n,U',X'} \longrightarrow \Lambda_{n,U',X'},$$

such that the following diagram, whose rows are exact, is commutative:

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \Lambda_{n,U',X'} & \longrightarrow & \Lambda_{n,X'} & \longrightarrow & \Lambda_{n,Y'} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle f'_{\Lambda_{n,U',X'}}} & & \downarrow{\scriptstyle f'_{\Lambda_{n,X'}}} & & \downarrow{\scriptstyle f'_{\Lambda_{n,Y'}}} & & \\ 0 & \longrightarrow & \Lambda_{n,U',X'} & \longrightarrow & \Lambda_{n,X'} & \longrightarrow & \Lambda_{n,Y'} & \longrightarrow & 0. \end{array} \tag{1.3}$$

We deduce in particular homomorphisms of complexes of Λ_n-modules

$$\begin{aligned}
f'_{H_{n,U',X'}} &= R\Gamma_{X'}(f'_{\Lambda_{n,U',X'}}) : H_{n,U',X'} \to H_{n,U',X'},\\
f'^{\vee}_{H_{n,U',X'}} &= (f'_{H_{n,U',X'}})^{\vee} : H^{\vee}_{n,U',X'} \to H^{\vee}_{n,U',X'},\\
g_{H_{n,U',X'}} &= R\Gamma_{X'}(g_{\Lambda_{n,U',X'}}) : H_{n,U',X'} \to H_{n,U',X'},\\
g^{\vee}_{H_{n,U',X'}} &= (g_{H_{n,U',X'}})^{\vee} : H^{\vee}_{n,U',X'} \to H^{\vee}_{n,U',X'},
\end{aligned}$$

such that the following relations hold:

$$g_{H_{n,U',X'}} \circ f'_{H_{n,U',X'}} = f'_{H_{n,U',X'}} \circ \varphi(g)_{H_{n,U',X'}}, \tag{1.4}$$

$$f'^{\vee}_{H_{n,U',X'}} \circ g^{\vee}_{H_{n,U',X'}} = \varphi(g)^{\vee}_{H_{n,U',X'}} \circ f'^{\vee}_{H_{n,U',X'}}. \tag{1.5}$$

Relation (1.5) shows (cf. Exposé XI on the general theory of traces, 5.2.1, 7.1) that the trace

$$\mathrm{Tr}^*_{\Lambda_n[G],\varphi}(f'^{\vee}_{H_{n,U',X'}}) \in \Lambda_n[G]_{\natural,\varphi} \simeq \mathcal{F}_!(G_{\natural,\varphi}, \Lambda_n) \qquad (*)^{28}$$

is defined.

Our first aim will be to give, under some additional hypotheses, an explicit formula for $\mathrm{Tr}^*_{\Lambda_n[G],\varphi}(f'^{\vee}_{H_{n,U',X'}})$ in terms of local invariants associated with f', terms which we shall define below.

2.

In fact, one can do better. For this, let n, m be two positive integers such that $m \geq n$. The ring homomorphisms

$$\alpha_{m,n} : \Lambda_m \longrightarrow \Lambda_n$$

give rise to homomorphisms of sheaves of rings on X':

$$\begin{aligned}
\alpha_{m,n,X'} &: \Lambda_{m,X'} \longrightarrow \Lambda_{n,X'},\\
\alpha_{m,n,U',X'} &: \Lambda_{m,U',X'} \longrightarrow \Lambda_{n,U',X'}.
\end{aligned}$$

Application of the Künneth formula gives

$$R\Gamma_{X'}(\Lambda_{m,X'}) \otimes^{\mathbb{L}}_{\Lambda_m} \Lambda_n \simeq R\Gamma_{X'}(\Lambda_{n,X'}), \tag{2.1}$$

$$R\Gamma_{X'}(\Lambda_{m,U',X'}) \otimes^{\mathbb{L}}_{\Lambda_m} \Lambda_n \simeq R\Gamma_{X'}(\Lambda_{n,U',X'}), \tag{2.2}$$

$$R\Gamma_{X'}(f'_{\Lambda_{m,X'}}) \otimes^{\mathbb{L}}_{\Lambda_m} \Lambda_n \simeq R\Gamma_{X'}(f'_{\Lambda_{n,X'}}), \tag{2.3}$$

$$R\Gamma_{X'}(f'_{\Lambda_{m,U',X'}}) \otimes^{\mathbb{L}}_{\Lambda_m} \Lambda_n \simeq R\Gamma_{X'}(f'_{\Lambda_{n,U',X'}}). \tag{2.4}$$

One deduces easily that

$$R\,\mathrm{Hom}_{\Lambda_m}(R\Gamma_{X'}(\Lambda_{m,U',X'}), \Lambda_m) \otimes^{\mathbb{L}}_{\Lambda_m} \Lambda_n \simeq R\,\mathrm{Hom}_{\Lambda_n}(R\Gamma_{X'}(\Lambda_{n,U',X'}), \Lambda_n), \tag{2.5}$$

$$f'^{\vee}_{H_{m,U',X'}} \otimes^{\mathbb{L}}_{\Lambda_m} \Lambda_n \simeq f'^{\vee}_{H_{n,U',X'}}. \tag{2.6}$$

[28] Cf. III B 5.12.

The morphism of perfect complexes $R\Gamma_{X'}(f'_{\Lambda_{n,X'}})$ (resp. $R\Gamma_{X'}(f'_{\Lambda_{n,U',X'}})$, $f'^{\vee}_{H_{n,U',X'}}$) is therefore obtained by extension of scalars (XI, 6.3) from the morphisms $R\Gamma_{X'}(f'_{\Lambda_{m,X'}})$ (resp. $R\Gamma_{X'}(f'_{\Lambda_{m,U',X'}})$, $f'^{\vee}_{H_{m,U',X'}}$) by means of the morphisms $\alpha_{m,n}$ (resp. $\alpha_{m,n}$, $\alpha_{m,n,G} : \Lambda_m[G] \to \Lambda_n[G]$).

Using (XI, 6.3, 6.3.2, 6.3.3), 2.3, and 2.6, one obtains the relations

$$\mathrm{Tr}^*_{\Lambda_n}(R\Gamma_{X'}(f'_{\Lambda_{n,X'}})) = \alpha_{m,n}(\mathrm{Tr}^*_{\Lambda_m}(R\Gamma_{X'}(f'_{\Lambda_{m,X'}}))), \tag{2.7}$$

$$\mathrm{Tr}^*_{\Lambda_n[G],\varphi}(f'^{\vee}_{H_{n,U',X'}}) = \alpha_{m,n,G}(\mathrm{Tr}^*_{\Lambda_m[G],\varphi}(f'^{\vee}_{H_{m,U',X'}})). \tag{2.8}$$

The system of functions

$$(\mathrm{Tr}_{\Lambda_n[G],\varphi}(f'^{\vee}_{H_{n,U',X'}}))_{n>0}$$

defines a function

$$\mathrm{Tr}_{\mathbb{Z}_\ell[G],\varphi}(f'^{\vee}_{H_{U',X'}(\ell)}) \in \mathcal{F}_!(G_{\natural\varphi}, \mathbb{Z}_\ell),$$

which is φ-central on G and has values in the ring $\mathbb{Z}_\ell$ of ℓ-adic integers.

Similarly, the elements $\mathrm{Tr}^*_{\Lambda_n}(R\Gamma_{X'}(f'_{\Lambda_{n,X'}}))$, $n \geq 1$, define an ℓ-adic integer

$$\mathrm{Tr}^*_{\mathbb{Z}_\ell}(f'_{R\Gamma_{X'}(\mathbb{Z}_\ell,X')}).$$

Our aim will be to find a formula for

$$\mathrm{Tr}^*_{\mathbb{Z}_\ell[G],\varphi}(f'^{\vee}_{H_{U',X'}(\ell)}).$$

3. The local Nielsen–Wecken invariant (cf. [1])

Suppose, in addition to the hypotheses described in number 1, that every orbit of G is contained in an affine open subset. Then a quotient $X = X'/G$ exists and, by formula 1.1, the endomorphism f' of X' descends to the quotient:

$$f : X \longrightarrow X.$$

We shall use the following notation:

$$\begin{aligned} &p : X' \longrightarrow X = X'/G \quad \text{for the canonical projection,}\\ &Y = p(Y') = Y'/G,\\ &U = X - Y. \end{aligned}$$

The open U' is a principal covering with structural group G. Let $x \in U$ be a fixed point of f. We shall associate with it a φ-conjugacy class (XI, 7.1), denoted $\mathrm{NW}_f^{G,\varphi}(x)$, as follows.

Let $x' \in U'$ be such that $p(x') = x$. Since U' is a principal covering with structural group G and since x is fixed by f, there exists a unique element $g \in G$ such that $f'(x') = gx'$. The φ-conjugacy class of g depends only on x. Indeed, if $p(x'') = x$, there exists $h \in G$ such that $hx'' = x'$. Consequently, if $f'(x'') = g'x''$, then

$$\begin{aligned} gx' = f'(x') = f'(hx'') = \varphi(h)f'(x'') = (\varphi(h)g'h^{-1})x',\\ g = \varphi(h)g'h^{-1}, \end{aligned}$$

that is, g and g' are φ-conjugate. Thus one obtains a well-defined φ-conjugacy class, the local Nielsen–Wecken invariant associated with the fixed point $x \in U$ of f, which will be denoted by $\mathrm{NW}_f^{G,\varphi}(x)$.

The φ-conjugacy class $\mathrm{NW}_f^{G,\varphi}(x)$ defines a φ-central function (cf. XI, 7.1)

$$\mathrm{NW}_f^{G,\varphi}(x) : G \longrightarrow \mathbb{Z}$$

with integer values, characterized by the following relations:

$$\mathrm{NW}_f^{G,\varphi}(x)(g) = \begin{cases} 1 & \text{if there exists } x' \in X' \text{ such that } (g^{-1}f')(x') = x' \\ & \qquad \text{and } p(x') = x, \\ 0 & \text{otherwise.} \end{cases} \tag{3.1}$$

4. Generalities on local terms

Suppose that X' is smooth over k and, in addition, that the number of fixed points of f is finite. It follows in particular that the number of fixed points of $g^{-1}f'$ is finite for every $g \in G$.

For each fixed point $x \in X$ of f, introduce the φ-central function

$$S_x(f', f, G, \varphi) : G \longrightarrow \mathbb{Q},$$

with rational values, defined by the formula

$$S_x(f', f, G, \varphi)(g) = \frac{1}{c^\varphi(g)} \sum_{x' \in X'^{g^{-1}f'}_x} (\nu_{x'}(g^{-1}f') - 1). \tag{4.1}$$

We have used the following notation:

$$c^\varphi(g) = \operatorname{card} G_g^\varphi, \qquad G_g^\varphi = \{x \in G \mid \varphi(x) g x^{-1} = g\}, \tag{4.2}$$

$$X'^{g^{-1}f'}_x = \{x' \in X' \mid p(x') = x, (g^{-1}f')(x') = x'\}, \tag{4.3}$$

$$\nu_{x'}(g^{-1}f') = \text{the multiplicity of the fixed point } x' \text{ of } g^{-1}f'. \tag{4.4}$$

By composition with the canonical inclusions

$$\mathbb{Q} \hookrightarrow \mathbb{Q}_\ell,$$

the function $S_x(f', f, G, \varphi)$ gives φ-central functions $S_{x,\ell}(f', f, G, \varphi)$ on G with values in the field $\mathbb{Q}_\ell$ of ℓ-adic numbers.

Conjecture 4.5. *For each $\ell \neq \mathrm{car}(k)$, the values of the function $S_{x,\ell}(f', f, G, \varphi)$ are ℓ-adic integers.*

We shall prove below that Conjecture 4.5 is true when the dimension of X is equal to 1.

Proposition 4.6. *Let R be a discrete valuation ring, $\mathfrak{m}$ its maximal ideal, π a uniformizer, $k = R/\mathfrak{m}$ its residue field, assumed algebraically closed, v its valuation, $f'_R : R \to R$ an endomorphism of R, and G a finite group of automorphisms of R. Suppose that the endomorphism f'_R and the*

automorphisms g_R induce the identity on k, and suppose in addition that an endomorphism of G is given,

$$\varphi : G \longrightarrow G,$$

satisfying

$$f'_R \circ g_R = \varphi(g)_R \circ f'_R.$$

If, for every $g \in G$, one writes

$$\nu(g_R^{-1} f'_R) = v(g_R^{-1} f'_R(\pi) - \pi),$$

and if $c^{\varphi}(g)$ (cf. 4.2) is decomposed in the form

$$c^{\varphi}(g) = p^s q, \qquad (p, q) = 1, \qquad p = \mathrm{car}(k),$$

then $q \mid (\nu(g_R^{-1} f'_R) - 1)$.

To prove Proposition 4.6 one reduces to the case $g = e$ and $\varphi = \mathrm{id}_G$. Indeed one first reduces to the case $g = e$ by associating with the situation (f'_R, G, g, φ) the situation

$$(f''_R = g_R^{-1} f'_R,\ G,\ e,\ \varphi' = \mathrm{int}(g) \circ \varphi),$$

where $\varphi'(a) = g^{-1}\varphi(a)g$, and by observing easily that

$$\nu(g_R^{-1} f') - 1 = \nu(f''_R) - 1$$

and

$$c^{\varphi}(g) = c^{\varphi'}(e) \qquad (G_g^{\varphi} = G_e^{\varphi'}) \qquad \text{(cf. 4.2)}.$$

To reduce simultaneously to the case $g = e$, $\varphi = \mathrm{id}_G$, note that one can associate with the situation (f''_R, G, e, φ') the situation

$$(f''_R, G_e^{\varphi'}, e, \mathrm{id}_{G_e^{\varphi'}}),$$

and that

$$G_e^{\varphi'} = (G_e^{\varphi'})_e^{\mathrm{id}_{G_e^{\varphi'}}}.$$

The proof of Proposition 4.6 essentially uses the following lemma.

Lemma 4.7. *With the hypotheses and notation of Proposition 4.6, suppose moreover that $\varphi = \mathrm{id}_G$, that is, that the operations of G on R commute with f'_R, and that $r = \nu(f'_R) \geq 2$. Let*

$$c = \mathrm{card}(\mathrm{Im}(G \longrightarrow \mathrm{Aut}_k(\mathfrak{m}/\mathfrak{m}^2))).$$

Then the following divisibility relation holds:

$$c \mid (r - 1).$$

Proof. It is clear that the integer r satisfies the following conditions:

a) the homomorphism

$$f'_r : A/\mathfrak{m}^r \longrightarrow A/\mathfrak{m}^r$$

induced by f'_R is the identity;

b) the homomorphism

$$f'_{r+1} : A/\mathfrak{m}^{r+1} \longrightarrow A/\mathfrak{m}^{r+1}$$

is different from the identity.

On the other hand, it is evident that G acts on all the vector spaces $\mathfrak{m}^i/\mathfrak{m}^{i+1}$ over k.

We first show that under the hypotheses of the lemma there exists a unique homomorphism of $k[G]$-modules

$$u(f'_R) : \mathfrak{m}/\mathfrak{m}^2 \longrightarrow \mathfrak{m}^r/\mathfrak{m}^{r+1}$$

satisfying the two following conditions:

1) $u(f'_R) \neq 0$;

2) $u(f'_R)(x \bmod \mathfrak{m}^2) = (f'_R(x) - x) \bmod \mathfrak{m}^{r+1}$, for every $x \in \mathfrak{m}$.

It is clear that condition a) implies $f'_R(x) - x \in \mathfrak{m}^r$ for every $x \in R$, which gives meaning to condition 2). This observation also gives the possibility of defining a homomorphism of abelian groups

$$\mathfrak{m} \longrightarrow \mathfrak{m}^r/\mathfrak{m}^{r+1}, \qquad x \longmapsto (f'_R(x) - x) \bmod \mathfrak{m}^{r+1}.$$

This homomorphism vanishes on $\mathfrak{m}^2$. Indeed, if $x_1, x_2 \in \mathfrak{m}$, then $f'_R(x_1x_2) - x_1x_2 \in \mathfrak{m}^{r+1}$ because, by condition a),

$$f'_R(x_1) = x_1 + \alpha_1, \quad \alpha_1 \in \mathfrak{m}^r,$$
$$f'_R(x_2) = x_2 + \alpha_2, \quad \alpha_2 \in \mathfrak{m}^r,$$

and hence

$$f'_R(x_1x_2) = f'_R(x_1)f'_R(x_2) = (x_1 + \alpha_1)(x_2 + \alpha_2) = x_1x_2 + x_1\alpha_2 + x_2\alpha_1 + \alpha_1\alpha_2,$$

and, plainly, $x_1\alpha_2 + x_2\alpha_1 + \alpha_1\alpha_2 \in \mathfrak{m}^{r+1}$.

It follows by passage to the quotient that we get a homomorphism of abelian groups

$$u(f'_R) : \mathfrak{m}/\mathfrak{m}^2 \longrightarrow \mathfrak{m}^r/\mathfrak{m}^{r+1}.$$

The homomorphism $u(f'_R)$ is in fact a homomorphism of vector spaces over k. To see this, one must show that for all $x \in \mathfrak{m}$, $\alpha \in R$,

$$f'_R(\alpha x) - \alpha x \equiv \alpha(f'_R(x) - x) \pmod{\mathfrak{m}^{r+1}},$$

that is,

$$f'_R(\alpha x) - \alpha f'_R(x) \in \mathfrak{m}^{r+1}. \tag{4.7.1}$$

But

$$f'_R(\alpha x) - \alpha f'_R(x) = (f'_R(\alpha) - \alpha)f'_R(x),$$

which gives (4.7.1), since

$$f'_R(\alpha) - \alpha \in \mathfrak{m}^r \quad \text{(condition a))}, \qquad f'_R(x) \in \mathfrak{m} \quad (x \in \mathfrak{m}).$$

The homomorphism $u(f'_R)$ is a homomorphism of $k[G]$-modules. Indeed, for $x \in \mathfrak{m}$ one has

$$\begin{aligned} u(f'_R)(g(x \bmod \mathfrak{m}^2)) &= (f'_R(gx) - gx) \bmod \mathfrak{m}^{r+1} \\ &= g(f'_R(x) - x) \bmod \mathfrak{m}^{r+1} = g\, u(f'_R)(x \bmod \mathfrak{m}^2). \end{aligned}$$

Finally, $u(f'_R) \neq 0$. Indeed, by condition b) there exists an element $x_0 \in R$ such that $f'_R(x_0) - x_0 \notin \mathfrak{m}^{r+1}$. But we need such an element in $\mathfrak{m}$. To obtain one, write x_0 in the form

$$x_0 = \frac{x}{x'}, \qquad x, x' \in \mathfrak{m}, \quad x' \notin \mathfrak{m}^{r+1}.$$

At least one of the elements x, x' satisfies the required condition.

Suppose, for contradiction, that simultaneously

$$f'_R(x) - x \in \mathfrak{m}^{r+1}, \qquad f'_R(x') - x' \in \mathfrak{m}^{r+1}.$$

Then, in the field of fractions K of A, one has

$$\frac{f'_R(x)}{x} \in 1 + \mathfrak{m}^r, \qquad \frac{f'_R(x')}{x'} \in 1 + \mathfrak{m}^r.$$

We may suppose that $f'_R(x') \neq 0$, since otherwise x' is the desired element. Since $1 + \mathfrak{m}^r$ is a multiplicative group, it follows that

$$\frac{x'}{f'_R(x')} \in 1 + \mathfrak{m}^r,$$

and consequently

$$\frac{f'_R(x)}{x} \cdot \frac{x'}{f'_R(x')} \in 1 + \mathfrak{m}^r.$$

This last relation implies

$$\frac{f'_R(x_0)}{x_0} \in 1 + \mathfrak{m}^r.$$

Indeed,

$$\begin{aligned} \frac{f'_R(x_0)}{x_0} - \frac{f'_R(x)}{x} \cdot \frac{x'}{f'_R(x')} &= \frac{f'_R(\frac{x}{x'})}{\frac{x}{x'}} - \frac{f'_R(x)}{x} \cdot \frac{x'}{f'_R(x')} \\ &= \frac{x' f'_R(\frac{x}{x'})}{x} - \frac{f'_R(x)}{x} \cdot \frac{x'}{f'_R(x')} \\ &= \frac{1}{x}\left(\frac{x' f'_R(x') f'_R(\frac{x}{x'}) - x' f'_R(x)}{f'_R(x')}\right) = 0. \end{aligned}$$

Thus $f'_R(x_0) - x_0 \in \mathfrak{m}^{r+1}$, a contradiction.

If the vector space

$$\mathrm{Hom}_k(\mathfrak{m}/\mathfrak{m}^2, \mathfrak{m}^r/\mathfrak{m}^{r+1})$$

is endowed with its usual G-module structure, its element $u(f'_R)$ belongs to the subspace

$$\mathrm{Hom}_k(\mathfrak{m}/\mathfrak{m}^2, \mathfrak{m}^r/\mathfrak{m}^{r+1})^G$$

of G-invariants.

It is classical that the vector space $\mathfrak{m}^i/\mathfrak{m}^{i+1}$ identifies canonically with the i-th tensor power $\bigotimes_k^i(\mathfrak{m}/\mathfrak{m}^2)$. Consequently $\mathrm{Hom}_k(\mathfrak{m}/\mathfrak{m}^2, \mathfrak{m}^r/\mathfrak{m}^{r+1})$ identifies by the homomorphism of contraction with the $(r-1)$-st tensor power $\bigotimes_k^{r-1}(\mathfrak{m}/\mathfrak{m}^2)$:

$$\gamma : \mathrm{Hom}_k(\mathfrak{m}/\mathfrak{m}^2, \mathfrak{m}^r/\mathfrak{m}^{r+1}) \longrightarrow \bigotimes_k^{r-1}(\mathfrak{m}/\mathfrak{m}^2).$$

Through γ, the G-module structure on the Hom-space is transported to the G-module structure on $\bigotimes_k^{r-1}(\mathfrak{m}/\mathfrak{m}^2)$ induced by that on $\mathfrak{m}/\mathfrak{m}^2$:

$$g(\xi_1 \otimes \xi_2 \otimes \cdots \otimes \xi_{r-1}) = g\xi_1 \otimes \cdots \otimes g\xi_{r-1}.$$

Denote by $\mu(f'_R)$ the image of $u(f'_R)$ under γ. Thus:

I) $0 \neq \mu(f'_R) \in \bigotimes_k^{r-1}(\mathfrak{m}/\mathfrak{m}^2)$;

II) $\mu(f'_R)$ is invariant under G.

We can now conclude the proof of Lemma 4.7. Since the vector space $\mathfrak{m}/\mathfrak{m}^2$ has dimension one,

$$\mathrm{Aut}_k(\mathfrak{m}/\mathfrak{m}^2) = k^*.$$

Therefore the image of $G \to \mathrm{Aut}_k(\mathfrak{m}/\mathfrak{m}^2)$ is a finite cyclic subgroup of k^*, generated by a primitive c-th root of unity ε. It is generated by the automorphism

$$\chi : \mathfrak{m}/\mathfrak{m}^2 \longrightarrow \mathfrak{m}/\mathfrak{m}^2, \qquad \xi \longmapsto \varepsilon\xi.$$

Since $\mu(f'_R)$ is invariant under G,

$$\begin{aligned}\mu(f'_R) &= \chi\mu(f'_R)\\ &= \chi \sum_i \xi_{1i} \otimes \xi_{2i} \otimes \cdots \otimes \xi_{r-1,i}\\ &= \sum_i \varepsilon\xi_{1i} \otimes \varepsilon\xi_{2i} \otimes \cdots \otimes \varepsilon\xi_{r-1,i}\\ &= \varepsilon^{r-1}\mu(f'_R),\end{aligned}$$

that is,

$$(1 - \varepsilon^{r-1})\mu(f'_R) = 0.$$

Since $\mu(f'_R) \neq 0$, it follows that $1 - \varepsilon^{r-1} = 0$, that is, $c \mid (r-1)$.

Proof of Proposition 4.6. We have already noted that one may reduce to the case $g = e$, $\varphi = \mathrm{id}_G$. If G_1 denotes the kernel of the homomorphism

$$G \longrightarrow \mathrm{Aut}_k(\mathfrak{m}/\mathfrak{m}^2),$$

then ramification theory gives

$$\mathrm{card}(G_1) = p^t.$$

Consequently, with the notation of Lemma 4.7,

$$\mathrm{card}(G) = p^t c.$$

Since, on the other hand, $c^{\mathrm{id}_G}(e) = \mathrm{card}(G)$, the assertion of Proposition 4.6 in the case $g = e$, $\varphi = \mathrm{id}_G$, and hence in general, follows from Lemma 4.7.

Corollary 4.8. *For each $\ell \neq \mathrm{car}(k)$, the image of the rational number*

$$\frac{\nu(g_R^{-1} f'_R) - 1}{c^{\varphi}(g)}$$

under the canonical inclusion

$$\mathbb{Q} \hookrightarrow \mathbb{Q}_\ell$$

is an ℓ-adic integer.

Proposition 4.9. *Conjecture 4.5 is true if the dimension of the scheme X is equal to* 1.

Proof. We introduce the endomorphism

$$\psi : G \longrightarrow G$$

defined by

$$\psi = \mathrm{int}_g \circ \varphi, \qquad \mathrm{int}_g(\xi) = g^{-1}\xi g.$$

It is easy to see that:

i) $\psi(G_{x'}) \subset G_{g^{-1}f'x'}$, where $G_{x'}$ is the stabilizer of the point x';

ii) $c^{\varphi}(g) = \mathrm{card}(G^{\psi})$, where $G^{\psi} = \{\xi \mid \psi(\xi) = \xi\}$;

iii) G^{ψ} acts on ${X'_x}^{g^{-1}f'}$;

iv) $\nu_{x'}(g^{-1}f') = \nu_{hx'}(g^{-1}f')$ for every $h \in G^{\psi}$;

v) $(g^{-1}f')(g_1 x) = \psi(g_1)(g^{-1}f')(x)$.

Consequently one can decompose ${X'_x}^{g^{-1}f'}$ as the union of its orbits and obtain

$$\sum_{x' \in {X'_x}^{g^{-1}f'}} (\nu_{x'}(g^{-1}f') - 1) = \sum_{x' \in {X'_x}^{g^{-1}f'}/G^{\psi}} \frac{\nu_{x'}(g^{-1}f') - 1}{\mathrm{card}(G^{\psi}_{x'})}\ \mathrm{card}(G^{\psi}), \tag{4.9.1}$$

where

$$\nu_{x'}(g^{-1}f') = \nu((g^{-1}f')_{\mathcal{O}_{x'}}),$$

that is,

$$S_x(f', f, G, \varphi)(g) = \sum_{x' \in {X'}^{g^{-1}f'}/G^{\psi}} \frac{\nu_{x'}(g^{-1}f') - 1}{\mathrm{card}(G^{\psi}_{x'})}. \tag{4.9.2}$$

Proposition 4.9 follows from Proposition 4.6.

5. Generalization of a Nielsen–Wecken type formula (cf. [1])

Proposition 5.1. With the hypotheses and notation of 1, 2, 3, and 4, suppose in addition that Y' is a finite subset of X'.

If ℓ is a prime number different from the characteristic of k, then:

a) the values of the φ-central function

$$\sum_{x\in Y^f} S_{x,\ell}(f,f',G,\varphi)$$

are ℓ-adic integers;

b) the following formula holds:

$$\mathrm{Tr}_{\mathbb{Z}_\ell[G],\varphi}(f'^{\vee}_{H_{U',X'}(\ell)}) = \sum_{x\in U^f}\nu_x(f)\mathrm{NW}_f^{G,\varphi}(x) + \sum_{x\in Y^f} S_{x,\ell}(f,f',G,\varphi). \tag{5.1.1}$$

Proof. It is clear that if equality b) is proved with everything regarded as functions with values in $\mathbb{Q}_\ell$, assertion a) follows at once, since $\mathrm{NW}_f^{G,\varphi}(x)$ and $\mathrm{Tr}_{\mathbb{Z}_\ell[G],\varphi}(f'^{\vee}_{H_{U',X'}(\ell)})$ are functions with values in $\mathbb{Z}_\ell$.

First, reducing modulo ℓ^n for every $n\geq 1$ and using (XI, 7.2.3.6), one sees that for every $g\in G$,

$$\begin{aligned} c^\varphi(g)\ \mathrm{Tr}_{\mathbb{Z}_\ell[G],\varphi}(f'^{\vee}_{H_{U',X'}(\ell)})(g) &= \mathrm{Tr}_{\mathbb{Z}_\ell}(g_{X'}^{-1}f')^{\vee}_{H_{U',X'}(\ell)} \\ &= \mathrm{Tr}_{\mathbb{Z}_\ell}(g_{X'}^{-1}f')_{H^{\vee}_{U',X'}(\ell)}. \end{aligned} \tag{5.2}$$

The commutative diagram (1.3), whose rows are exact, gives (XI, §4)

$$\mathrm{Tr}_{\mathbb{Z}_\ell}(g_{X'}^{-1}f')_{H^{\vee}_{U',X'}(\ell)} = \mathrm{Tr}_{\mathbb{Z}_\ell}(g_{X'}^{-1}f')_{R\Gamma_{X'}(\mathbb{Z}_{\ell,X'})} - \mathrm{Tr}^*_{\mathbb{Z}_\ell}(g_{Y'}^{-1}f'_{Y'})_{R\Gamma_{Y'}(\mathbb{Z}_{\ell,Y'})}. \tag{5.3}$$

The two terms on the right-hand side of (5.3) can be evaluated using the classical Lefschetz formula (cf.). (For the last term this is in fact a trivial Lefschetz formula):

$$\mathrm{Tr}_{\mathbb{Z}_\ell}(g_{X'}^{-1}f')_{R\Gamma_{X'}(\mathbb{Z}_{\ell,X'})} = \sum_{x\in X^f}\sum_{x'\in X'^{\,g_{X'}^{-1}f'}_x}\nu_{x'}(g_{X'}^{-1}f'), \tag{5.4}$$

$$\mathrm{Tr}^*_{\mathbb{Z}_\ell}(g_{Y'}^{-1}f'_{Y'})_{R\Gamma_{Y'}(\mathbb{Z}_{\ell,Y'})} = \text{the number of fixed points of } g_{Y'}^{-1}f'_{Y'}. \tag{5.5}$$

Consequently,

$$\mathrm{Tr}_{\mathbb{Z}_\ell}(g_{X'}^{-1}f')_{H^{\vee}_{U',X'}(\ell)} = \sum_{x\in U^f}\sum_{x'\in X'^{\,g_{X'}^{-1}f'}_x}\nu_{x'}(g_{X'}^{-1}f') - \sum_{x\in Y^f}\sum_{x'\in X'^{\,g_{X'}^{-1}f'}_x}(1-\nu_{x'}(g_{X'}^{-1}f')). \tag{5.6}$$

But for a given $x\in U^f$, the set $X'^{\,g_{X'}^{-1}f'}_x$ is nonempty if and only if $\mathrm{NW}_f^{G,\varphi}(x)=1$. Moreover,

$$\mathrm{card}\, X'^{\,g_{X'}^{-1}f'}_x = c^\varphi(g), \qquad x\in U, \tag{5.7}$$

$$\nu_{x'}(g_{X'}^{-1}f') = \nu_x(f), \qquad x\in U. \tag{5.8}$$

Relations (5.2) and (5.6) therefore give

$$\mathrm{Tr}_{\mathbb{Z}_\ell[G],\varphi}(f'^{\vee}_{H_{U',X'}(\ell)})(g) = \sum_{x\in U^f}\nu_x(f)\mathrm{NW}_f^{G,\varphi}(x)(g) - \sum_{x\in Y^f}\sum_{x'\in X'^{\,g_{X'}^{-1}f'}_x}\frac{1-\nu_{x'}(g_{X'}^{-1}f')}{c^\varphi(g)}, \tag{5.9}$$

which is the formula to be proved.

5.10. Special cases

a) The unramified case: $Y' = \emptyset$, that is, $Y = \emptyset$.

In this case formula (5.1.1) becomes

$$\mathrm{Tr}_{\mathbb{Z}_\ell[G],\varphi}(f'^{\vee}_{H_{U'},X'}(\ell)) = \sum_{x\in X^f} \nu_x(f)\mathrm{NW}_f^{G,\varphi}(x). \tag{5.11}$$

b) The case of multiplicities 1: $\nu_{x'}(g_{X'}^{-1}f') = 1$ for every $x' \in Y'^{g_{Y'}^{-1}f'_{Y'}}$ and every $g \in G$.

In this case formula 5.1.1 reduces to formula 5.11. This case occurs in particular if $\dim X = 1$ and $\nu_x(f) = 1$ for every $y \in Y$.

6. Application to a Lefschetz formula

6.1

We keep the notation and the conditions of number 1[29], except where the contrary is expressly stated. Let A be a commutative noetherian Λ_n-algebra, let F be a constructible sheaf, for the étale topology, of perfect A-modules on X, and let

$$u : f^*(F) \longrightarrow F$$

be a homomorphism of sheaves of A-modules.

In particular, one obtains an endomorphism of the pair (X, F):

$$(u, f) : (X, F) \longrightarrow (X, F),$$

and consequently an endomorphism of complexes of A-modules:

$$R\Gamma_X(u, f) : R\Gamma_X(F) \longrightarrow R\Gamma_X(F).$$

Since the scheme X is proper over k by hypothesis and the sheaf F is constructible and torsion, the finiteness theorem (SGA 4, XVII 5) ensures that the complex $R\Gamma_X(F)$ is a perfect complex of A-modules. The trace

$$\mathrm{Tr}_A(R\Gamma_X(u, f))$$

is therefore defined, with

$$\mathrm{Tr}_A(R\Gamma_X(u, f)) \in A.$$

Our aim will be to give, under some additional hypotheses, an explicit formula for $\mathrm{Tr}_A(R\Gamma_X(u, f))$ in terms of local invariants associated with the fixed points of f.

[29] X^f denotes the set of closed fixed points of X.

6.2. Definition of the local terms

Suppose that X' is irreducible of dimension one and that the restriction to U' of the sheaf $F' = p^*(F)$ is constant.

If the number of fixed points of f' is finite, as will be assumed from now on, one may always suppose that $X^f \subset Y^f$.

The sheaf $F'|_{U'}$ is therefore defined by an A-module M on which G acts:

$$F'|_{U'} \simeq M_{U'}.$$

Indeed, if η (resp. η') denotes the generic point of X (resp. X'), and $\bar{\eta}$ (resp. $\bar{\eta}'$) a geometric point over η (resp. η'), then

$$p(\eta') = \eta, \qquad F_{\bar{\eta}} \simeq F'_{\bar{\eta}'}.$$

The complex F' is isomorphic to M, and consequently M is a perfect A-module.

On the other hand, if the morphism f' is not constant, it fixes the generic point of X'. Consequently the morphism $(p^*(u), f')$ of the pair (X', F') induces a morphism on the fibre $F'_{\bar{\eta}'}$,

$$u'_{\bar{\eta}'} : F'_{\bar{\eta}'} \longrightarrow F'_{\bar{\eta}'},$$

and hence, evidently, a morphism of A-modules

$$u_M : M \longrightarrow M.$$

One easily sees that the following relation is satisfied:

$$u_M(\varphi(g)m) = g u_M(m) \qquad \forall m \in M, \quad \forall g \in G. \tag{6.2.1}$$

The dual $M^\vee$ of M with respect to A is therefore endowed with an $A[G]$-module structure and an endomorphism

$$u_M^\vee : M^\vee \longrightarrow M^\vee$$

such that

$$u_M^\vee(gx) = \varphi(g) u_M^\vee(x) \qquad \forall g \in G, \quad \forall x \in M^\vee.$$

Moreover, $M^\vee$ is a perfect A-module, and consequently the trace $\mathrm{Tr}_A(g^{-1}u_M^\vee)$ is defined for every $g \in G$.

Let $x \in X^f$ be a closed fixed point of f. The morphism u induces an endomorphism of the module F_x, the fibre of the sheaf F at the point x (the closed points of X are identified with the points of $X(x)$):

$$u_x : F_x \longrightarrow F_x.$$

The trace $\mathrm{Tr}_A(u_x)$ gives a first local invariant associated with the fixed point x.

We introduce another local invariant $\alpha_x(f, u, f', G, \varphi)$, an element of the ring A, by the formula

$$\alpha_x(f, u, f', G, \varphi) = \sum_{g \in G_{\natural, \varphi}} S_{x, \ell^n}(f, f', G, \varphi)(g) \, \mathrm{Tr}_A(g^{-1} u_M^\vee), \tag{6.2.2}$$

where the function

$$S_{x, \ell^n}(f, f', G, \varphi) : G \longrightarrow \Lambda_n$$

is obtained from the function $i_\ell \circ S_x(f, F', G, \varphi)$ (cf. 4) by reduction modulo $\ell^n\mathbb{Z}$, i.e.

$$S_{x, \ell^n}(f, f', G, \varphi)(g) = (i_\ell \circ S_x(f, f', G, \varphi))(g) \bmod \ell^n\mathbb{Z}.$$

6.3. A Lefschetz formula

Under the hypotheses and with the notation of 5.1, 6.1, and 6.2, one has the formula

$$\mathrm{Tr}_A(\mathrm{R}\Gamma_X(u,f)) = \sum_{x\in X^f} \tau_x(f,u,f',G,\varphi), \tag{6.3.1}$$

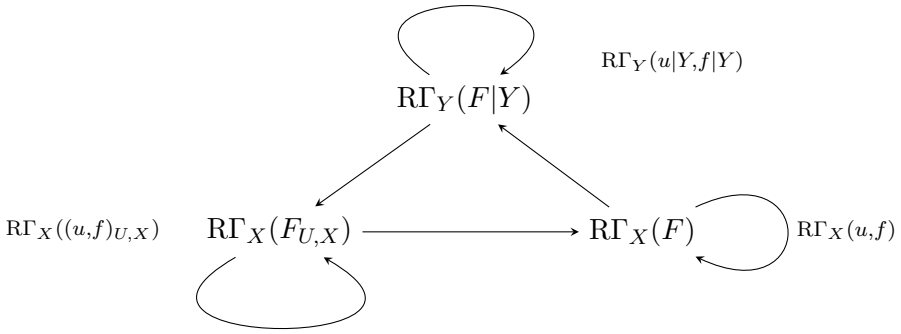
where

$$\tau_x(f,u,f',G,\varphi) = \mathrm{Tr}_A(u_x) - \alpha_x(f,u,f',G,\varphi). \tag{6.3.2}$$

Proof. Since the subscheme Y is stable under f, the morphism

$$(u,f) : (X,F) \longrightarrow (X,F)$$

induces an endomorphism of distinguished triangles



(6.3.3)

and hence the relation

$$\mathrm{Tr}_A(\mathrm{R}\Gamma_X(u,f)) = \mathrm{Tr}_A(\mathrm{R}\Gamma_X((u,f)_{U,X})) + \mathrm{Tr}_A(\mathrm{R}\Gamma_Y(u|Y,f|Y)). \tag{6.3.4}$$

The last term in (6.3.4) can be made explicit by the elementary Lefschetz formula and the fact that one may always suppose $X^f = Y^f$:

$$\mathrm{Tr}_A(\mathrm{R}\Gamma_Y(u|_Y,f|_Y)) = \sum_{x\in X^f} \mathrm{Tr}_A(u_x). \tag{6.3.5}$$

On the other hand,

$$\mathrm{R}\Gamma_X((u,f)_{U,X}) \simeq \mathrm{R}\Gamma^G \mathrm{R}\Gamma_{X'}((u',f')_{U',X'}), \quad (u' = p^*(u)), \tag{6.3.6}$$

$$F_{U',X'} \simeq \Lambda_{n,U',X'} \otimes^{\mathbf{L}}_{\Lambda_n} M, \qquad (u',f')_{U',X'} = f'_{\Lambda_{n,U',X'}} \otimes_{\Lambda_n} M, \tag{6.3.7}$$

whence, by the Künneth formula,

$$\mathrm{R}\Gamma_{X'}(u',f')_{U',X'} \simeq \mathrm{R}\Gamma_{X'}(f'_{\Lambda_{n,U',X'}}) \otimes^{\mathbf{L}}_{\Lambda_n} u_M. \tag{6.3.8}$$

It follows from (6.3.8) that

$$\mathrm{R}\Gamma_{X'}((u',f')_{U',X'})^\vee \simeq (\mathrm{R}\Gamma_{X'}(f'_{\Lambda_{n,U',X'}}))^\vee \otimes^{\mathbf{L}}_{\Lambda_n} A \otimes^{\mathbf{L}}_A u^\vee_M. \tag{6.3.9}$$

Using formula 6.3.6, one obtains

$$\mathrm{R}\Gamma_X((u,f)_{U,X}) = \mathrm{R}\Gamma_{X'}(f'_{\Lambda_{n,U',X'}}) \otimes^{\mathbf{L}}_{A[G]} u^\vee_M, \tag{6.3.10}$$

and hence, taking account of the general formula (cf. Exposé XI, 7.5.9),

$$\mathrm{Tr}_A((u,f)_{U,X}) = \sum_{g\in G_{\natural,\varphi}} \mathrm{Tr}_{\Lambda_n[G],\varphi}({f'}^{\vee}_{H_{n,U',X'}})(g)\,\mathrm{Tr}_A(g^{-1}u_M^{\vee}). \tag{6.3.11}$$

But the trace $\mathrm{Tr}_{\Lambda_n[G],\varphi}({f'}^{\vee}_{H_{n,U',X'}})$ is calculated using the Nielsen–Wecken formula (cf. Proposition 5.1 b)), evidently after reduction modulo $\ell^n\mathbb{Z}$.

Taking account of the relation $X^f = Y^f$, one obtains

$$\mathrm{Tr}_{\Lambda_n[G],\varphi}({f'}^{\vee}_{H_{n,U',X'}})(g) = \sum_{x\in X^f} S_{x,\ell^n}(f,f',G,\varphi)(g). \tag{6.3.12}$$

Combining relations 6.3.12, 6.3.11, 6.3.5, and 6.3.4 gives the formula in the statement.

6.4. Remarks on the local terms

a)

It is easy to see that, if $g \in G$, then one has the relation

$$\alpha_x(f,u,g^{-1}f',G,\varphi_g) = \alpha_x(f,u,f',G,\varphi), \tag{6.4.1}$$

where

$$\varphi_g(\xi) = (\mathrm{int}_g \circ \varphi)(\xi) = g^{-1}\varphi(\xi)g, \qquad \forall \xi \in G. \tag{6.4.2}$$

Relation 6.4.1 allows us always to reduce, after replacing f' by $g^{-1}f'$ and φ by φ_g, to the case where there exists at least one point $x' \in {X'_x}^{f'}$.

b)

Let $x' \in {X'_x}^{f'}$ and let $G_{x'}$ be the stabilizer of the point x'. Evidently $G_{x'}$ is stable under φ, and hence one obtains an endomorphism

$$\varphi_{x'} = \varphi|_{G_{x'}} : G_{x'} \longrightarrow G_{x'}.$$

Let $X'/G_{x'}$ denote the quotient scheme obtained from X' by the equivalence relation defined by $G_{x'}$, let $F'/G_{x'}$ be the endomorphism of $X'/G_{x'}$ obtained from the endomorphism f' of X' by the same equivalence relation, and let x' denote the class of the point x' modulo this equivalence relation.

The canonical projection

$$p : X' \longrightarrow X'/G = X$$

factors as

$$p : X' \xrightarrow{p_1} X'/G_{x'} \xrightarrow{p_2} X = X'/G.$$

Taking the inverse image by p_2 of the homomorphism u, one obtains a homomorphism

$$v = p_2(u) : (f'/G_{x'})^*(p_2^*(F)) \longrightarrow p_2^*(F).$$

It is easy to see that

$$\alpha_{x'}(f'/G_{x'},v,f',G_{x'},\varphi_{x'}) = \alpha_x(f,u,f',G,\varphi) \qquad (x = p(x')). \tag{6.4.3}$$

Thus one may always reduce to the "totally ramified" case, that is, to the case where the fibre of the point x is reduced to one point.

c) The "tamely ramified" case.

Suppose that there exists $x' \in p^{-1}(x)$ such that

$$f'(x') = x', \qquad p(x') = x,$$

a case to which one can always reduce, cf. case a), and suppose that the order of the group $G_{x'}$ is prime to the characteristic of the field k. Then one has

$$\alpha_x(f, u, f', G, \varphi) = S_{x,\ell^n}(f, f', G, \varphi)(e)\ \mathrm{Tr}_A(u_M^\vee). \tag{6.4.4}$$

Taking case b) into account, one may suppose that $G = G_{x'}$. Formula (6.4.4) then follows from the following lemma.

Lemma 6.4.5

If the following relations hold:

$$\nu_{x'}(f') > 1,$$
$$\nu_{x'}(g^{-1}f') > 1,$$

then g belongs to the first ramification group G_1 (cf. 4.7):

$$g \in G_1,$$

that is, g induces the identity on the vector space $\mathfrak{m}_{x'}/\mathfrak{m}_{x'}^2$.

Proof

Let $\widehat{\mathcal{O}}_{x'} = k[[T]]$. The automorphism of $\mathfrak{m}/\mathfrak{m}^2$ induced by g^{-1} is determined by a root of unity $\varepsilon(g^{-1}) \in k$ by the condition

$$g^{-1}T = \varepsilon(g^{-1})T \mod \mathfrak{m}^2,$$

where $\mathfrak{m}$ is the maximal ideal of the ring $k[[T]]$.

On the other hand, the hypothesis $\nu_{x'}(f') > 1$ gives

$$f'(T) = T + a_\nu T^\nu + a_{\nu+1}T^{\nu+1} + \cdots, \qquad \nu \geq 2.$$

Consequently

$$g^{-1}f'(T) = \varepsilon(g^{-1})T + b_\nu T^\nu + b_{\nu+1}T^{\nu+1} + \cdots,$$

and the hypothesis $\nu(g^{-1}f') > 1$ implies $\varepsilon(g^{-1}) = 1$, as required.

d) The case of a sheaf F which is not ramified at the fixed points of the endomorphism f.

In this case the local term $\tau_x(f, u, f', G, \varphi)$ is given by the formula

$$\tau_x(f, u, f', G, \varphi) = \nu_x(f)\ \mathrm{Tr}_A(u_x), \tag{6.4.6}$$

and consequently depends only on the pair (f, u).

Indeed, in this case one has

$$S'_{x,\ell^n}(f, f', G, \varphi)(g) = \begin{cases} 0 & \text{if there exists } x' \in X' \text{ such that } (g^{-1}f')(x') = x' \text{ or} \\ & \text{equivalently if the } \varphi\text{-conjugacy class of } g \text{ coincides with} \\ & \text{the class } \mathrm{NW}_f^{G,\varphi}(x) \text{ (cf. 3);} \\ \nu_x(f) - 1 & \text{otherwise.} \end{cases} \tag{6.4.7}$$

It follows in particular that

$$S_{x,\ell^n}(f, f'; G, \varphi)(g) = 0 \qquad \text{if } g \notin \mathrm{NW}_f^{G,\varphi}(x). \tag{6.4.8}$$

We therefore find

$$\begin{aligned} \tau_x(f, u, f', G, \varphi) &= \nu_x(f)\,\mathrm{Tr}_A(g^{-1}u_M^\vee) = \nu_x(f)\,\mathrm{Tr}_A(g^{-1}u')_{x'} \\ &= \nu_x(f)\,\mathrm{Tr}_A(u_x). \end{aligned} \tag{6.4.9}$$

7. Comments on the conditions of validity of the Lefschetz formula

7.1

Of course, in practice one starts with a scheme X proper over k and an endomorphism

$$(u, f) : (X, F) \longrightarrow (X, F),$$

such that:

- F is a constructible sheaf of A-modules,
- the set X^f of fixed points of f is finite.

The problem is to define, under these conditions, local terms $\tau_x(u, f)$, $x \in X^f$, such that

$$(*) \qquad \mathrm{Tr}_A(R\Gamma_X(u, f)) = \sum_{x \in X^f} \tau_x(u, f).$$

Using the two duality theorems, global and local, Verdier succeeds in defining terms $\tau_x(u, f)$ such that formula (*) is true (cf. III). Unfortunately, the explicit determination of the $\tau_x(u, f)$, as defined by Verdier, in terms of known local invariants seems difficult; hence the interest of the definitions proposed in the preceding chapter.[30]

By contrast, these latter definitions require additional hypotheses on F, f, and u, namely the existence of U, U', G, f', φ having the properties required in 5.1, 6.1, 6.2.

Proposition 7.2. Let X be a smooth scheme of dimension 1, let F be constructible, and let

$$(u, f) : (X, F) \longrightarrow (X, F)$$

[30] See, however, III B for the comparison of the local terms of 6.3.1 with Verdier's local terms.

be an endomorphism such that the morphism of sheaves

$$u : f^*(F) \longrightarrow F$$

is an isomorphism. Under these conditions there exist U, U', G, f', φ satisfying the conditions of 5.1, 6.1, 6.2.

Proof. Let U be the largest open subset of X on which F is locally constant, and let Y denote its complement. The set Y is stable under f:

$$f(Y) \subset Y.$$

Indeed, suppose by contradiction that there is a $y \in Y$ such that $f(y) \in U$. The sheaf $f^*(F)$ is then locally constant in a neighbourhood of y, and using the isomorphism u it follows that F is locally constant in a neighbourhood of y, which is absurd.

If f is constant, the proof of the proposition is trivial. We shall therefore suppose that f is not constant. If η is the generic point of X, then $f(\eta) = \eta$.

Let $i_\eta : \mathrm{Spec}(k(\eta)) \hookrightarrow X$ be the canonical inclusion, put $F_\eta = i_\eta^*(F)$, and let

$$u_\eta : f_\eta^*(F_\eta) \longrightarrow F_\eta$$

be the morphism, in fact the isomorphism, of sheaves induced by u, where f_η is of course the restriction of f to $\mathrm{Spec}(k(\eta))$.

Translating everything into terms of H-modules,

$$H = \mathrm{Gal}(k(\eta)_s/k(\eta)), \qquad k(\eta)_s \text{ a separable closure of } k(\eta),$$

one obtains the isomorphisms

$$H \xrightarrow{\Psi} H \qquad F_{\bar\eta} \xrightarrow{u_{\bar\eta}} F_{\bar\eta},$$

where $F_{\bar\eta}$ has an H-module structure and the following relation holds:

$$u_{\bar\eta}(gx) = \Psi(g)\, u_{\bar\eta} x, \qquad g \in H, \quad x \in F_{\bar\eta}.$$

If H_1 is the largest distinguished subgroup of H of finite index such that $F_{\bar\eta}^{H_1} = F_{\bar\eta}$, then $\Psi(H_1) = H_1$. Such a subgroup exists because the sheaf F_η is constructible.

Let $K \supset k(\eta)$ be the Galois extension of $k(\eta)$ corresponding to the subgroup H_1, and let X' be the normalization of X in K. It is clear that one can define an endomorphism

$$f' : X' \longrightarrow X'$$

and an endomorphism

$$H/H_1 = G \xrightarrow{\varphi} G$$

such that the system U, U', f', G, φ satisfies the required conditions.

Example 7.3. Let X be a prescheme defined over the finite field $\mathbb{F}_p$, where p is a prime number, let $\mathrm{fr}_X : X \to X$ be the Frobenius endomorphism (cf. XIV), and let F be a sheaf of Λ-modules on X.

If Y, S are schemes over $\mathbb{F}_p$, and if Y is a scheme over S, we denote by

$$\mathrm{Fr}_{Y/S} : Y \longrightarrow Y^{(p/S)}$$

the relative Frobenius morphism (cf. XIV 2).

We obtain a morphism of sheaves on $X_{\text{ét}}$

$$(\mathrm{fr}_X)_*(F) \longrightarrow F$$

by setting, for every étale X-prescheme U,

$$(\mathrm{fr}_X)_*(F)(U) = F(\mathrm{fr}_X^{-1}(U)) = F(U^{(p/X)}) \xrightarrow{F(\mathrm{Fr}_{U/X})} F(U).$$

This morphism is in fact an isomorphism. Its inverse

$$F(\mathrm{Fr}_{/X})^{-1} : F \longrightarrow (\mathrm{fr}_X)_*(F)$$

defines by adjunction a morphism

$$\mathrm{Fr}^*_{F/X} : (\mathrm{fr}_X)^*(F) \longrightarrow F$$

which is an isomorphism.

If in particular X is smooth of dimension 1 and F is constructible, the pair

$$(\mathrm{Fr}^*_{F/X}, \mathrm{fr}_X) : (X, F) \longrightarrow (X, F)$$

therefore falls under Proposition 7.2.

Exposé XV

FROBENIUS MORPHISM AND RATIONALITY OF L-FUNCTIONS

by C. Houzel

§ 1. Frobenius morphism

No. 1. Frobenius endomorphism

Definition 1. Let p be a prime number. A prescheme X is said to be of characteristic p if $p \cdot 1_{\mathcal{O}_X} = 0$.

This condition is equivalent to the following one: the unique morphism $X \to \mathrm{Spec}(\mathbb{Z})$ factors through $\mathrm{Spec}(\mathbb{F}_p) \to \mathrm{Spec}(\mathbb{Z})$; moreover, such a factorization is unique.

We shall denote by $(\mathrm{Sch})_p$ the full subcategory of the category of preschemes whose objects are the preschemes of characteristic p. By the preceding remark, the category $(\mathrm{Sch})_p$ is naturally isomorphic to the category of $\mathbb{F}_p$-preschemes.

If X is a prescheme of characteristic p, the pair

$$\mathrm{fr}_X = (\mathrm{id}_{|X|}, \psi), \qquad \psi : \mathcal{O}_X \longrightarrow \mathcal{O}_X, \qquad \psi(f) = f^p$$

for every section f of $\mathcal{O}_X$ over an open set, is an endomorphism of X, because ψ is visibly an endomorphism of the sheaf of rings $\mathcal{O}_X$.

Definition 2. Let X be a prescheme of characteristic p. The endomorphism fr_X thus defined is called the Frobenius endomorphism of X.

The Frobenius endomorphism fr_X depends functorially on the prescheme X of characteristic p; that is, for every morphism $g : X \to Y$ of preschemes of characteristic p, the following diagram is commutative:

$$\begin{array}{ccc} X & \xrightarrow{\mathrm{fr}_X} & X \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle g} \\ Y & \xrightarrow[\mathrm{fr}_Y]{} & Y. \end{array}$$

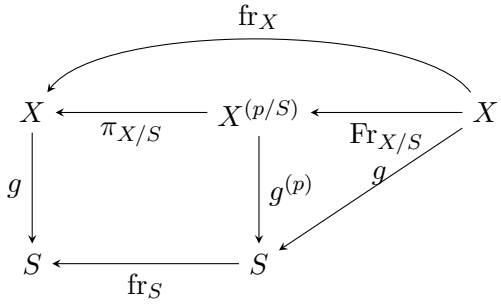
In other words, we have defined an endomorphism fr of the identity functor $\mathrm{id}_{(\mathrm{Sch})_p}$.

No. 2. Relative Frobenius morphism

Let S be a prescheme of characteristic p; all S-preschemes are then also of characteristic p. If X is an S-prescheme, one sees that fr_X factors through the projection

$$\pi_{X/S} : X \times_S (S, \mathrm{fr}_S) \longrightarrow X,$$

where (S, fr_S) denotes S regarded as an S-prescheme by means of the morphism fr_S. We shall denote the fibre product $X \times_S (S, \mathrm{fr}_S)$ by $X^{(p/S)}$, or even by $X^{(p)}$ if no confusion can result. The unique S-morphism from X to $X^{(p/S)}$ whose composite with $\pi_{X/S}$ is fr_X is denoted by $\mathrm{Fr}_{X/S}$; thus one obtains a commutative diagram in which the square is cartesian.



It is clear that $X^{(p/S)}$ depends functorially on the S-prescheme X; the functor

$$p_S : X \longmapsto X^{(p/S)}$$

is simply base change by the morphism $\mathrm{fr}_S : S \to S$. Like every base change, it commutes with projective limits and with sums, and preserves properties such as being of finite type, separated, affine, projective, flat, étale, and so on. Commutation with projective limits shows that if X is endowed with an algebraic structure, for example a group or algebra structure, then $X^{(p/S)}$ is naturally endowed with an algebraic structure of the same kind.

Using the functoriality of fr_X with respect to X, one sees that the morphism $\mathrm{Fr}_{X/S}$ depends functorially on the S-prescheme X, so that a functorial morphism

$$\mathrm{Fr}_{X/S} : \mathrm{id}_{(\mathrm{Sch})/S} \longrightarrow p_S$$

has been defined.

Definition 3. Let S be a prescheme of characteristic p and X an S-prescheme. The S-morphism

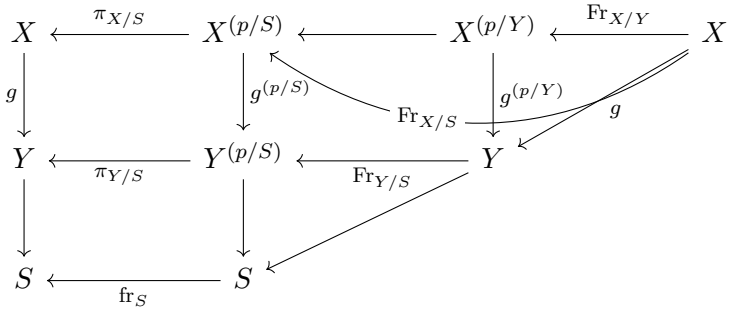
$$\mathrm{Fr}_{X/S} : X \longrightarrow X^{(p/S)}$$

is called the Frobenius morphism of X relative to S.

The first formal properties of the Frobenius morphism are stated in the following proposition.

Proposition 1.

a) *(Transitivity.)* Let S be a prescheme of characteristic p, and let $g : X \to Y$ be an S-morphism of S-preschemes. The natural diagram relating X, $X^{(p/S)}$, $X^{(p/Y)}$, Y, $Y^{(p/S)}$, and S is commutative and its three squares are cartesian.



b) *(Base change.)* Let $g : S' \to S$ be a morphism of preschemes of characteristic p, and let X be an S-prescheme. There is a canonical isomorphism

$$X^{(p/S)} \times_S S' \simeq (X \times_S S')^{(p/S')}$$

functorial in X, that is, $(X^{(p/S)})' \simeq X'^{(p/S')}$ when the result of base change by g is marked with a prime; moreover

$$\mathrm{Fr}_{X'/S'} = (\mathrm{Fr}_{X/S})'$$

modulo the identification allowed by the preceding isomorphism.

The proof is immediate.

Proposition 2. Let S be a prescheme of characteristic p and X an S-prescheme.

a) The relative Frobenius morphism

$$\mathrm{Fr}_{X/S} : X \longrightarrow X^{(p/S)}$$

is integral, surjective, and radicial; hence it is a universal homeomorphism.

b) If $X \to S$ is an open immersion, then $X^{(p)} = X$ and $\mathrm{Fr}_{X/S} = \mathrm{id}_X$. If $X \to S$ is a closed immersion, identifying X with a closed ringed subspace $(|X|, \mathcal{O}_S/\mathcal{J})$ of S, then

$$X^{(p)} = (|X|, \mathcal{O}_S/\mathcal{J}^p)$$

and $\mathrm{Fr}_{X/S} = (\mathrm{id}_{|X|}, \varphi)$, where $\varphi : \mathcal{O}_S/\mathcal{J}^p \to \mathcal{O}_S/\mathcal{J}$ is the evident augmentation.

c) Suppose that X is locally of finite presentation over S.

1) The following three conditions are equivalent:

(i) X is unramified over S,
(ii) $\mathrm{Fr}_{X/S}$ is unramified,
(iii) $\mathrm{Fr}_{X/S}$ is a monomorphism.

2) Likewise, the following three conditions are equivalent:

(i') X is étale over S,
(ii') $\mathrm{Fr}_{X/S}$ is étale,
(iii') $\mathrm{Fr}_{X/S}$ is an isomorphism.

We prove a). The composite $\pi_{X/S} \circ \mathrm{Fr}_{X/S} = \mathrm{fr}_X$ is visibly integral, surjective, and radicial; it follows that $\mathrm{Fr}_{X/S}$ is radicial (EGA I 3.5.6 (ii)). Moreover $\pi_{X/S}$ is separated and radicial, because it is deduced from fr_S by the base change $X \to S$; it follows that $\mathrm{Fr}_{X/S}$ is integral (EGA II 6.1.5 (v)) and surjective.

The proof of b) is evident, observing that

$$\mathcal{J}\mathcal{O}_{(S,\mathrm{fr}_S)} = \mathcal{J}^p$$

for every ideal $\mathcal{J}$ of $\mathcal{O}_S$.

Proof of c). It is known that for a morphism to be a monomorphism, respectively an isomorphism, it is necessary and sufficient that it be radicial and unramified, respectively radicial, étale, and surjective. This gives the equivalence of (ii) and (iii), respectively of (ii') and (iii'). It remains to prove that (i) is equivalent to (ii), and (i') to (ii').

For this, one uses the differential criterion of unramifiedness (SGA I 3) and the isomorphism

$$\Omega^1_{X/S} \simeq \Omega^1_{X/X^{(p)}}$$

given by the canonical exact sequence

$$\mathrm{Fr}^*_{X/S}(\Omega^1_{X^{(p)}/S}) \longrightarrow \Omega^1_{X/S} \longrightarrow \Omega^1_{X/X^{(p)}} \longrightarrow 0$$

(SGA II 4), in which the first arrow is visibly zero, because $\Omega^1_{X^{(p)}/S}$ is generated by the differentials of sections of $\mathcal{O}_{X^{(p)}}$, and the differential $d_{X/S}$ vanishes on $(\mathcal{O}_X)^p$ and on $\mathcal{O}_S$. Thus (i) is equivalent to (ii).

Now suppose X is étale over S; the same is true of $X^{(p)}$ by base change, and consequently the morphism $\mathrm{Fr}_{X/S} : X \to X^{(p)}$ is étale. Conversely, suppose that $\mathrm{Fr}_{X/S}$ is étale; it is unramified, hence X is unramified over S. In other words, the structural morphism $g : X \to S$ is locally on X, for the étale topology, a closed immersion (SGA I, cor. 7.8). We may therefore suppose that g is a closed immersion of finite presentation, and it remains to see that, if $\mathrm{Fr}_{X/S}$ is an isomorphism, then g is an open immersion. Now X is defined by an ideal $\mathcal{J}$ of finite type,

$$X = (|X|, \mathcal{O}_S/\mathcal{J}),$$

and, by b),

$$X^{(p)} = (|X|, \mathcal{O}_S/\mathcal{J}^p), \qquad \mathrm{Fr}_{X/S} = (\mathrm{id}_{|X|}, \mathcal{O}_S/\mathcal{J}^p \to \mathcal{O}_S/\mathcal{J}).$$

To say that $\mathrm{Fr}_{X/S}$ is an isomorphism is therefore to say that $\mathcal{J} = \mathcal{J}^p$; since $\mathcal{J}$ is of finite type, Nakayama's lemma implies that $\mathcal{J}_s = 0$, or $\mathcal{J}_s = \mathcal{O}_{S,s}$, for every point $s \in S$, whence the conclusion.

No. 3. Effect on a module. Examples

Let S be a prescheme of characteristic p and X an S-prescheme. For every $\mathcal{O}_X$-Module $\mathcal{E}$, a sheaf for the Zariski topology, set

$$\mathcal{E}^{(p/S)} = \pi_{X/S}^*(\mathcal{E}) = \mathcal{E} \otimes_{\mathcal{O}_X} \mathcal{O}_{X^{(p)}} = \mathcal{E} \otimes_{\mathcal{O}_S} \mathcal{O}_{(S,\mathrm{fr}_S)}.$$

This is an $\mathcal{O}_{X^{(p)}}$-Module, and one has

$$\mathcal{E}^{(p/X)} \simeq \mathrm{Fr}_{X/S}^*(\mathcal{E}^{(p/S)}).$$

The most interesting case is the case $X = S$; one may then write $\mathcal{E}^{(p)}$ instead of $\mathcal{E}^{(p/S)}$ without risk of confusion, and $\mathcal{E}^{(p)} = \mathrm{fr}_S^*(\mathcal{E})$. The adjunction morphism

$$\mathcal{E} \longrightarrow \mathrm{fr}_{S*}\,\mathrm{fr}_S^*(\mathcal{E})$$

is a morphism of abelian sheaves $\mathcal{E} \to \mathcal{E}^{(p)}$ which is not $\mathcal{O}_S$-linear, but is "p-linear" in the evident sense; it is visibly a universal p-linear morphism from $\mathcal{E}$ to an $\mathcal{O}_S$-Module.

It is clear that $\mathcal{E}^{(p)}$ depends functorially on $\mathcal{E}$, and that the functor $\mathcal{E} \mapsto \mathcal{E}^{(p)}$ is right exact, but not exact in general; it commutes with tensor products:

$$(\mathcal{E} \otimes_{\mathcal{O}_X} \mathcal{F})^{(p)} \simeq \mathcal{E}^{(p)} \otimes_{\mathcal{O}_{X^{(p)}}} \mathcal{F}^{(p)},$$

and preserves properties such as being quasi-coherent, of finite type, of finite presentation, flat, locally free, and so on. In particular, if $\mathcal{L}$ is an invertible sheaf on S, one immediately sees that $\mathcal{L}^{(p)}$ is canonically isomorphic to $\mathcal{L}^{\otimes p}$, because the morphism $\mathcal{L} \to \mathcal{L}^{\otimes p}$ defined by raising sections to their p-th tensor power is a universal p-linear morphism.

If $\mathcal{A}$ is an $\mathcal{O}_S$-Algebra, then $\mathcal{A}^{(p)}$ has an $\mathcal{O}_S$-Algebra structure deduced from that of $\mathcal{A}$. Suppose $\mathcal{A}$ is quasi-coherent, respectively graded and quasi-coherent; the same is true of $\mathcal{A}^{(p)}$, and

$$\mathrm{Spec}(\mathcal{A}^{(p)}) = \mathrm{Spec}(\mathcal{A} \otimes_{\mathcal{O}_S} \mathcal{O}_{(S,\mathrm{fr}_S)}) \simeq \mathrm{Spec}(\mathcal{A}) \times_S (S, \mathrm{fr}_S) = \mathrm{Spec}(\mathcal{A})^{(p)},$$

respectively

$$\mathrm{Proj}(\mathcal{A}^{(p)}) = \mathrm{Proj}(\mathcal{A} \otimes_{\mathcal{O}_S} \mathcal{O}_{(S,\mathrm{fr}_S)}) \simeq \mathrm{Proj}(\mathcal{A}) \times_S (S, \mathrm{fr}_S) = \mathrm{Proj}(\mathcal{A})^{(p)}.$$

The projection $\pi_{\mathrm{Spec}(\mathcal{A})/S} : \mathrm{Spec}(\mathcal{A})^{(p)} \to \mathrm{Spec}(\mathcal{A})$, respectively $\pi_{\mathrm{Proj}(\mathcal{A})/S}$, is identified with the morphism deduced from $\mathcal{A} \to \mathcal{A}^{(p)}$. On the other hand, $\mathrm{Fr}_{\mathrm{Spec}(\mathcal{A})/S}$, respectively $\mathrm{Fr}_{\mathrm{Proj}(\mathcal{A})/S}$, comes from a homomorphism of $\mathcal{O}_S$-Algebras

$$\mathcal{A}^{(p)} = \mathcal{A} \otimes_{\mathcal{O}_S} \mathcal{O}_{(S,\mathrm{fr}_S)} \longrightarrow \mathcal{A}$$

which sends $a \otimes f$ to $a^p f$, for every section a of $\mathcal{A}$ and every section f of $\mathcal{O}_S$. To see this, observe that the composite of this homomorphism with $\mathcal{A} \to \mathcal{A}^{(p)}$, on the right, is raising to the p-th power in $\mathcal{A}$.

Consider the particular case where $\mathcal{A}$ is the symmetric algebra $\mathrm{Sym}(\mathcal{E})$ of a quasi-coherent $\mathcal{O}_S$-Module $\mathcal{E}$; it is clear that $\mathcal{A}^{(p)} \simeq \mathrm{Sym}(\mathcal{E}^{(p)})$, hence

$$\mathbb{V}(\mathcal{E}^{(p)}) \simeq \mathrm{Spec}(\mathcal{A}^{(p)}) \simeq \mathrm{Spec}(\mathcal{A})^{(p)} = \mathbb{V}(\mathcal{E})^{(p)},$$

$$\mathbb{P}(\mathcal{E}^{(p)}) \simeq \mathrm{Proj}(\mathcal{A}^{(p)}) \simeq \mathrm{Proj}(\mathcal{A})^{(p)} = \mathbb{P}(\mathcal{E})^{(p)}.$$

As for $\mathrm{Fr}_{\mathbb{V}(\mathcal{E})/S}$, respectively $\mathrm{Fr}_{\mathbb{P}(\mathcal{E})/S}$, it factors in the following way:

$$\mathbb{V}(\mathcal{E}) \longrightarrow \mathbb{V}(\mathrm{Sym}^p(\mathcal{E})) \longrightarrow \mathbb{V}(\mathcal{E}^{(p)}),$$

respectively

$$\mathbb{P}(\mathcal{E}) \longrightarrow \mathbb{P}(\mathrm{Sym}^p(\mathcal{E})) \longrightarrow \mathbb{P}(\mathcal{E}^{(p)}),$$

where the first arrow is defined by the canonical morphism

$$\mathrm{Sym}(\mathrm{Sym}^p(\mathcal{E})) \longrightarrow \mathrm{Sym}(\mathcal{E})$$

which comes from $\mathrm{Sym}^p(\mathcal{E}) \to \mathrm{Sym}(\mathcal{E})$, while the second is defined by the morphism of $\mathcal{O}_S$-Modules

$$\mathcal{E}^{(p)} \longrightarrow \mathrm{Sym}^p(\mathcal{E})$$

coming from the p-linear morphism $\mathcal{E} \to \mathrm{Sym}^p(\mathcal{E})$ given by raising sections to their p-th symmetric power. In the case $X = \mathbb{P}(\mathcal{E})$, let us compute the fundamental sheaf $\mathcal{O}_{X^{(p)}}(1)$:

$$\mathcal{O}_{X^{(p)}}(1) = (\mathrm{Sym}(\mathcal{E})^{(p)}(1))^{\sim} = (\mathrm{Sym}(\mathcal{E})(1)^{(p)})^{\sim} \simeq \mathcal{O}_X(1)^{(p/S)}.$$

When $\mathcal{E} = \mathcal{O}_S^n$, $\mathrm{Sym}(\mathcal{E}) = \mathcal{O}_S[T_1, \ldots, T_n]$ and $X = \mathbb{V}(\mathcal{E}) = S[T_1, \ldots, T_n]$, respectively $X = \mathbb{P}(\mathcal{E}) = \mathbb{P}_S^{n-1}$, it is clear that $\mathcal{E}^{(p)} \simeq \mathcal{O}_S^n = \mathcal{E}$, so that $X^{(p)} = X$. The Frobenius morphism $\mathrm{Fr}_{X/S}$ comes from the endomorphism of the algebra $\mathcal{O}_S[T_1, \ldots, T_n]$ which sends T_i to T_i^p $(i = 1, \ldots, n)$.

Now consider a prescheme X, affine of finite type, respectively projective, over S, defined by an ideal, respectively a homogeneous ideal,

$$\mathcal{J} \subset \mathcal{O}_S[T_1, \ldots, T_n].$$

Thus $X = \mathrm{Spec}(\mathcal{A})$, respectively $X = \mathrm{Proj}(\mathcal{A})$, where

$$\mathcal{A} = \mathcal{O}_S[T_1, \ldots, T_n]/\mathcal{J}.$$

One sees that

$$\mathcal{A}^{(p)} \simeq \mathcal{O}_S[T_1, \ldots, T_n]/\mathcal{J}',$$

where $\mathcal{J}'$ is the image in $\mathcal{O}_S[T_1, \ldots, T_n]$ of $\mathcal{J}^{(p)} = \mathcal{J} \otimes_{\mathcal{O}_S} \mathcal{O}_{(S,\mathrm{fr}_S)}$; the ideal $\mathcal{J}'$ is deduced from $\mathcal{J}$ by raising the coefficients of the polynomials to the p-th power. One has $X^{(p)} = \mathrm{Spec}(\mathcal{A}^{(p)})$, respectively $\mathrm{Proj}(\mathcal{A}^{(p)})$, and the Frobenius morphism

$$\mathrm{Fr}_{X/S} : X \longrightarrow X^{(p)}$$

is defined by raising the coordinates T_i to the p-th power; this determines a morphism $\mathcal{A}^{(p)} \to \mathcal{A}$.

4. Iterated Frobenius morphism; perfect preschemes

For every integer $\nu \geq 0$, the iterated endomorphism fr_X^ν depends functorially on the prescheme X of characteristic p. Thus, if S is a prescheme of characteristic p and X is an S-prescheme, fr_X^ν factors, in a unique way, as an S-morphism

$$\mathrm{Fr}_{X/S}^\nu : X \longrightarrow X^{(p^\nu/S)},$$

where

$$X^{(p^\nu/S)} = X \times_S (S, \mathrm{fr}_S^\nu),$$

followed by the projection $X^{(p^\nu/S)} \to X$. The morphism $\mathrm{Fr}_{X/S}^\nu$ depends functorially on the S-prescheme X and is compatible with change of the base S (cf. no. 2, prop. 1b)). Moreover it is clear that

$$X^{(p^\nu/S)} = X^{(p^\nu)} \simeq \left(X^{(p^{\nu-1})}\right)^{(p)}$$

and that

$$\mathrm{Fr}_{X/S}^\nu = (\mathrm{Fr}_{X/S}^{\nu-1})^{(p)} \circ \mathrm{Fr}_{X/S},$$

modulo the identification allowed by the preceding canonical isomorphism.

Definition 4. A prescheme S of characteristic p is said to be perfect if fr_S is an automorphism of S.

If S is a perfect prescheme of characteristic p and X is an S-prescheme, one sees immediately that $X^{(p/S)}$ is identified with the prescheme X considered as an S-prescheme by means of the morphism $\mathrm{fr}_S^{-1} \circ g : X \to S$, where g is the structural morphism of X into S; modulo this identification, $\mathrm{Fr}_{X/S} = \mathrm{fr}_X$.

As an example of a perfect prescheme, we shall meet $S = \mathrm{Spec}(\mathbb{F}_q)$, where $q = p^\nu$ is a power of the characteristic p; indeed, in this case $\mathrm{fr}_S^\nu = \mathrm{id}_S$. If X is an S-prescheme, one sees that

$$X^{(p^\nu/S)} = X, \qquad \mathrm{Fr}_{X/S}^\nu = \mathrm{fr}_X^\nu .$$

Note that for $\nu = 1$ one obtains $S = \mathrm{Spec}(\mathbb{F}_p)$, for which $\mathrm{fr}_S = \mathrm{id}_S$; the S-preschemes are the preschemes of characteristic p; over this base S, $X^{(p/S)} = X$ and $\mathrm{Fr}_{X/S} = \mathrm{fr}_X$.

§ 2. Frobenius correspondence

1. Definition

Let X be a prescheme of characteristic p, and let F be a sheaf of sets on $X_{\text{ét}}$. For every étale X-prescheme U one has

$$(\mathrm{fr}_X)_*(F)(U) = F(\mathrm{fr}_X^{-1}(U)) = F(U^{(p/X)}),$$

and the Frobenius morphism $\mathrm{Fr}_{U/X} : U \to U^{(p/X)}$ defines a map

$$F(\mathrm{Fr}_{U/X}) : \mathrm{fr}_{X*}(F)(U) \longrightarrow F(U),$$

which is visibly functorial in U (since $\mathrm{Fr}_{U/X}$ is functorial in U). Thus one obtains a morphism of sheaves on $X_{\text{ét}}$:

$$(\mathrm{fr}_X)_*(F) \longrightarrow F.$$

Now, when U is étale over X, $\mathrm{Fr}_{U/X}$ is an isomorphism (§ 1 no. 2, prop. 2c)), hence the same is true of $F(\mathrm{Fr}_{U/X})$; it follows that the preceding morphism is an isomorphism. In the case where F is endowed with an algebraic structure, for example if it is a sheaf of Λ-modules, where Λ is a given base ring, this isomorphism is compatible with the algebraic structure. The inverse

$$F(\mathrm{Fr}_{/X})^{-1} : F \longrightarrow \mathrm{fr}_{X*}(F)$$

of this isomorphism defines, since $(\mathrm{fr}_X)^*$ is left adjoint to the functor $(\mathrm{fr}_X)_*$, a morphism

$$\mathrm{Fr}^*_{F/X} : (\mathrm{fr}_X)^*(F) \longrightarrow F.$$

One can even say more: since fr_X is a universal homeomorphism (§ 1 no. 2, prop. 2a)), the functors $(\mathrm{fr}_X)^*$ and $(\mathrm{fr}_X)_*$ are quasi-inverse to each other; consequently $\mathrm{Fr}^*_{F/X}$ is an isomorphism, just as is the morphism $F(\mathrm{Fr}_{/X})^{-1}$ from which it comes.

Definition 1. Given a prescheme X of characteristic p and a sheaf of sets F on $X_{\text{ét}}$, the Frobenius correspondence on (X, F) is the pair $(\mathrm{fr}_X, \mathrm{Fr}^*_{F/X})$ formed by the Frobenius endomorphism fr_X of X and the isomorphism

$$\mathrm{Fr}^*_{F/X} = (F(\mathrm{Fr}_{/X})^{-1})^\sharp : (\mathrm{fr}_X)^*(F) \longrightarrow F.$$

Of course one defines in the same way a class of iterated Frobenius correspondence $(\mathrm{fr}^\nu_X, (\mathrm{Fr}^*_{F/X})^\nu)$ for every integer $\nu \geq 0$; the isomorphism

$$(\mathrm{Fr}^*_{F/X})^\nu : (\mathrm{fr}^\nu_X)^*(F) \longrightarrow F$$

is equal to

$$(\mathrm{Fr}^*_{F/X})^{\nu-1} \circ (\mathrm{fr}^{\nu-1}_X)^*(\mathrm{Fr}^*_{F/X})$$

or also to

$$\mathrm{Fr}^*_{F/X} \circ \mathrm{fr}^*_X((\mathrm{Fr}^*_{F/X})^{\nu-1})$$

for $\nu \geq 1$.

Let us examine the particular case where F is representable by an étale prescheme V over X; then $(\mathrm{fr}_X)^*(F) = V^{(p/X)}$, $F(V) = \mathrm{Hom}_X(V, V)$,

$$(\mathrm{fr}_X)^*(F)(V) = F(V^{(p/X)}) = \mathrm{Hom}_X(V^{(p/X)}, V),$$

and $F(\mathrm{Fr}_{V/X})$ is the map from $\mathrm{Hom}_X(V^{(p/X)}, V)$ to $\mathrm{Hom}_X(V, V)$ which sends a morphism ψ to $\psi \circ \mathrm{Fr}_{V/X}$. Thus $\mathrm{Fr}^*_{F/X}$ is identified with a morphism from $V^{(p/X)}$ to V, which is the image of id_V under the inverse map $F(\mathrm{Fr}_{V/X})^{-1}$ of the preceding one. This shows that for $F = V$ étale over X one has

$$\mathrm{Fr}^*_{V/X} = (\mathrm{Fr}_{V/X})^{-1}.$$

Note that if the sheaf F is constant, then it is clear that

$$(\mathrm{fr}_X)^*(F) = F, \qquad \mathrm{Fr}^*_{F/X} = \mathrm{id}_F\,.$$

Proposition 1.

a) The isomorphism $\mathrm{Fr}^*_{F/X}$ depends functorially on the sheaf F; in other words there is a functorial isomorphism

$$\mathrm{Fr}^*_{/X} : \mathrm{fr}^*_X \longrightarrow \mathrm{id}_{\widetilde{X}_{\text{ét}}},$$

where $\widetilde{X}_{\text{ét}}$ is the category of sheaves of sets on $X_{\text{ét}}$.

b) The Frobenius correspondence $(\mathrm{fr}_X, \mathrm{Fr}^*_{F/X})$ on (X, F) is compatible with change of the base X. That is, if $\mathcal{F}$ denotes the fibred category over $(\mathrm{Sch})_p$ of sheaves, for the étale topology, on variable preschemes of characteristic p, the functors fr^*_X, $X \in \mathrm{ob}(\mathrm{Sch})_p$, define a cartesian $(\mathrm{Sch})_p$-functor

$$\mathrm{fr}^* : \mathcal{F} \longrightarrow \mathcal{F},$$

and the morphisms $\mathrm{Fr}^*_{F/X}$, $X \in \mathrm{ob}(\mathrm{Sch})_p$, $F \in \mathrm{ob}\,\widetilde{X}_{\text{ét}}$, define a functorial $(\mathrm{Sch})_p$-morphism

$$\mathrm{Fr}^*_{/} : \mathrm{fr}^* \longrightarrow \mathrm{id}_{\mathcal{F}}$$

which is an isomorphism.

c) Conversely, these properties characterize $\mathrm{Fr}^*_{/}$; that is, there exists a unique functorial $(\mathrm{Sch})_p$-morphism from fr^* to $\mathrm{id}_{\mathcal{F}}$.

Notice that statement b) implies statement a); the latter is entirely evident.

Let us prove b). Let $g : X' \to X$ be a morphism of preschemes of characteristic p, and let F be a sheaf on $X_{\text{ét}}$. Put $F' = g^*(F)$ and, more generally, mark by a prime the inverse image by g of any object given over X. Since

$$g \circ \mathrm{fr}_{X'} = \mathrm{fr}_X \circ g,$$

one has

$$\mathrm{fr}^*_{X'}(F') = \mathrm{fr}^*_{X'}(g^*F) = g^*(\mathrm{fr}^*_X F) = (\mathrm{fr}^*_X F)',$$

whence the fact that the fr^*_X define a cartesian functor fr^* over $(\mathrm{Sch})_p$. It remains to prove that

$$\mathrm{Fr}^*_{F'/X'} = (\mathrm{Fr}^*_{F/X})'.$$

Using the properties of adjoint functors, one sees that this amounts to showing that the image of $F'(\mathrm{Fr}_{/X'})^{-1}$ under the bijection

$$\mathrm{Hom}_{X'}(F', \mathrm{fr}_{X'*}(F')) = \mathrm{Hom}_{X'}(g^*F, \mathrm{fr}_{X'*}\, g^*F) \simeq \mathrm{Hom}_X(F, g_*\, \mathrm{fr}_{X'*}\, g^*F)$$

(with g^* left adjoint to g_*) coincides with the image of $F(\mathrm{Fr}_{/X})^{-1}$ under the map

$$\mathrm{Hom}_X(F, \mathrm{fr}_{X*}\, F) \longrightarrow \mathrm{Hom}_X(F, \mathrm{fr}_{X*}\, g_* g^* F) = \mathrm{Hom}_X(F, g_*\, \mathrm{fr}_{X'*}\, g^* F)$$

defined by the adjunction morphism $F \xrightarrow{\alpha} g_* g^* F$; in other words, one must show that

$$\alpha \circ F(\mathrm{Fr}_{/X}) = g_*(F'(\mathrm{Fr}_{/X'})) \circ \mathrm{fr}_{X*}(\alpha),$$

This says that for every prescheme U étale over X there is a commutative diagram

$$\begin{array}{ccc} F(U^{(p/X)}) & \xrightarrow{F(\mathrm{Fr}_{U/X})} & F(U) \\ \downarrow & & \downarrow \\ F'(U'^{(p/X')}) & \xrightarrow[F'(\mathrm{Fr}_{U'/X'})]{} & F'(U'), \end{array}$$

where the vertical arrows are the canonical maps; but this follows immediately from

$$\mathrm{Fr}_{U'/X'} = (\mathrm{Fr}_{U/X})'$$

(§ 1, no. 2, prop. 1b)).

To prove c), after composing with $(\mathrm{Fr}^*_{/})^{-1}$, we are reduced to proving that $\mathrm{id}_{\mathcal{F}}$ has only one $(\mathrm{Sch})_p$-endomorphism, namely the identity. If ψ is a $(\mathrm{Sch})_p$-endomorphism of $\mathrm{id}_{\mathcal{F}}$, let F be a sheaf on a prescheme X of characteristic p, and let U be an étale prescheme over X. We know that $F(U)$ is identified with $\mathrm{Hom}_U(U, F|U)$, and $\psi_F(U) : F(U) \to F(U)$ with the map

$$s \longmapsto \psi_{F|U} \circ s = s \circ \psi_U,$$

where $s \in \mathrm{Hom}_U(U, F|U)$; since the final sheaf U of $\widetilde{U}_{\text{ét}}$ has no endomorphism other than the identity, one has $\psi_U = \mathrm{id}_U$. It follows that $\psi_F(U)$ is also the identity of $F(U)$, and hence that $\psi = \mathrm{id}_{\mathcal{F}}$.

Of course, if the sheaf F is endowed with an algebraic structure, the isomorphism $\mathrm{Fr}^*_{F/X}$ is compatible with this structure; for example, if F is a sheaf of groups on the prescheme X of characteristic p, $\mathrm{Fr}^*_{F/X}$ is an isomorphism of sheaves of groups. Let Λ be a ring and let F be a sheaf of Λ-modules on X; then $\mathrm{Fr}^*_{F/X}$ is an isomorphism of sheaves of Λ-modules. More generally, if $F^\bullet$ is a complex of Λ-modules, one immediately defines an isomorphism

$$\mathrm{Fr}^*_{F^\bullet/X} : \mathrm{fr}^*_X(F^\bullet) \longrightarrow F^\bullet$$

which is equal to $\mathrm{Fr}^*_{F^i/X}$ on the component of degree i, thanks to proposition 1a). In this case the pair $(\mathrm{fr}_X, \mathrm{Fr}^*_{F^\bullet/X})$ is indeed a correspondence, in the usual sense, on $(X, F^\bullet)$; this correspondence is functorial in $F^\bullet$ and compatible with change of the base X (Proposition 1a), b)).

2. Effect on cohomology

Proposition 2. Let X be a prescheme of characteristic p.

a) For every sheaf of sets F on $X_{\text{ét}}$, the endomorphism of $H^0(X, F)$ defined by $(\mathrm{fr}_X, \mathrm{Fr}^*_{F/X})$, that is, the composite

$$H^0(X, F) \longrightarrow H^0(X, \mathrm{fr}^*_X(F)) \longrightarrow H^0(X, F),$$

where the first arrow is the canonical map arising from the contravariant character of $H^0(X, F)$ with respect to X, and the second is $H^0(X, \mathrm{Fr}^*_{F/X})$, is the identity of $H^0(X, F)$.

b) For every sheaf of groups F on $X_{\text{ét}}$, the endomorphism of $H^1(X, F)$ defined by $(\mathrm{fr}_X, \mathrm{Fr}^*_{F/X})$, that is,

$$H^1(X, F) \longrightarrow H^1(X, \mathrm{fr}^*_X F) \longrightarrow H^1(X, F),$$

is the identity.

c) For every left bounded complex F of Λ-modules on $X_{\text{ét}}$, the endomorphism of $\mathrm{R}\Gamma_X(F)$ defined by $(\mathrm{fr}_X, \mathrm{Fr}^*_{F/X})$, that is, the composite

$$\mathrm{R}\Gamma_X(F) \longrightarrow \mathrm{R}\Gamma_X(\mathrm{fr}^*_X F) \longrightarrow \mathrm{R}\Gamma_X(F),$$

is the identity.

We first establish a); b) and c) will be deduced from it. Let ψ_F be the considered endomorphism of $H^0(X,F)$. It is clear that ψ_F depends functorially on F and that $\psi_X = \mathrm{id}_{H^0(X,X)}$. Every element s of $H^0(X,F)$ is identified with a morphism of sheaves $s : X \to F$ such that s is the image under $H^0(X,s)$ of the unique element of $H^0(X,X)$; since

$$\psi_F \circ H^0(X,s) = H^0(X,s) \circ \psi_X = H^0(X,s),$$

by the preceding remarks, one sees that $\psi_F(s) = s$ for every s, hence $\psi_F = \mathrm{id}_{H^0(X,F)}$.

Note that ψ_F is also the composite

$$H^0(X,F) \longrightarrow H^0(X, \mathrm{fr}_{X*}F) \longrightarrow H^0(X,F),$$

where the first arrow is $H^0(X, F(\mathrm{Fr}_{/X})^{-1})$ and the second is the canonical map, which is nothing but the identity. Similarly, the endomorphisms considered in b) and c) factor as

$$H^1(X,F) \longrightarrow H^1(X, \mathrm{fr}_{X*}F) \longrightarrow H^1(X,F),$$

and

$$\mathrm{R}\Gamma_X(F) \longrightarrow \mathrm{R}\Gamma_X(\mathrm{fr}_{X*}F) \longrightarrow \mathrm{R}\Gamma_X(F).$$

To establish b), we shall use a monomorphism $F \to G$ of F into a sheaf of groups G such that $H^1(X,G) = 0$. Then $\mathrm{fr}_{X*}F \to \mathrm{fr}_{X*}G$ is a monomorphism and $H^1(X, \mathrm{fr}_{X*}G) = 0$. Introduce the quotient homogeneous sheaf of sets $C = G/F$. Since fr_X is integral, surjective, and radicial, the functors fr_X^* and fr_{X*} are quasi-inverse equivalences of categories (SGA VIII theorem 1.1). It follows that

$$\mathrm{fr}_{X*}(C) \simeq \mathrm{fr}_{X*}(G)/\,\mathrm{fr}_{X*}(F),$$

and the exact cohomology sequence (SGA XII proposition 3.1) shows that the considered endomorphism of $H^1(X,F)$ arises, by passage to the quotient, from

$$\psi_C : H^0(X,C) \longrightarrow H^0(X,C),$$

which is the identity by a). This endomorphism is therefore $\mathrm{id}_{H^1(X,F)}$.

Assertion c) is proved analogously, using a complex I that is injective in each degree and isomorphic to F in the derived category D^+, built from the Λ-modules. The complex $\mathrm{fr}_{X*}(I)$ is injective in each degree and isomorphic to $\mathrm{fr}_{X*}(F)$ in D^+, since fr_{X*} is an equivalence of categories. One may then identify $\mathrm{R}\Gamma_X(F)$ with $H^0(X,I)$ and $\mathrm{R}\Gamma_X(\mathrm{fr}_{X*}F)$ with $H^0(X, \mathrm{fr}_{X*}I)$; one sees that the considered endomorphism of $\mathrm{R}\Gamma_X(F)$ is identified with ψ_I, which is the identity. This endomorphism is therefore $\mathrm{id}_{\mathrm{R}\Gamma_X(F)}$.

3. Behavior of products

Let X and X' be preschemes of characteristic p. Their product $X \times X'$ is identical with the fibred product $X \times_e X'$, where $e = \mathrm{Spec}(\mathbb{F}_p)$. It is clear that

$$\mathrm{fr}_{X\times X'} = \mathrm{fr}_X \times \mathrm{fr}_{X'} = (\mathrm{fr}_X \times \mathrm{id}_{X'}) \circ (\mathrm{id}_X \times \mathrm{fr}_{X'}) = (\mathrm{id}_X \times \mathrm{fr}_{X'}) \circ (\mathrm{fr}_X \times \mathrm{id}_{X'}).$$

It follows immediately that, for every X-prescheme Y and every X'-prescheme Y', there is a canonical isomorphism

$$(Y \times Y')^{(p/X\times X')} \simeq Y^{(p/X)} \times Y'^{(p/X')};$$

modulo this isomorphism one can write

$$\mathrm{Fr}_{Y\times Y'/X\times X'} = \mathrm{Fr}_{Y/X} \times \mathrm{Fr}_{Y'/X'}\,.$$

Proposition 3. Let X and X' be preschemes of characteristic p, let Λ be a commutative ring, let F be a sheaf of Λ-modules on $X_{\text{ét}}$, and let F' be a sheaf of Λ-modules on $X'_{\text{ét}}$. One has

$$\begin{aligned}\mathrm{Fr}^*_{F\boxtimes_\Lambda F'/X\times X'} &= \mathrm{Fr}^*_{F/X} \otimes \mathrm{Fr}^*_{F'/X'} \\ &= (\mathrm{Fr}^*_{F/X} \otimes \mathrm{id}_{\mathrm{fr}^*_{X'}F'}) \circ (\mathrm{id}_F \otimes \mathrm{Fr}^*_{F'/X'}) \\ &= (\mathrm{id}_{\mathrm{fr}^*_X F} \otimes \mathrm{Fr}^*_{F'/X'}) \circ (\mathrm{Fr}^*_{F/X} \otimes \mathrm{id}_{F'}).\end{aligned}$$

To write these equalities, one has identified

$$\mathrm{fr}^*_{X\times X'}(F \boxtimes_\Lambda F')$$

with the tensor product $\mathrm{fr}^*_X(F) \otimes_\Lambda \mathrm{fr}^*_{X'}(F')$ by means of the canonical isomorphism.

The two sides of the first equality depend functorially on F and F', and are compatible with change of the base X or the base X'. Moreover they are compatible with passage to the inductive limit in F or in F', since the tensor product commutes with inductive limits and it is clear that

$$\mathrm{Fr}^*_{(\varinjlim F_i)/X} = \varinjlim \mathrm{Fr}^*_{F_i/X};$$

this permits reduction to the case where $F = \Lambda_X$ and $F' = \Lambda_{X'}$, in which case it is evident.

Corollary. With the data of proposition 3, the endomorphisms of $\mathrm{R}\Gamma_{X\times X'}(F \boxtimes F')$ defined respectively by

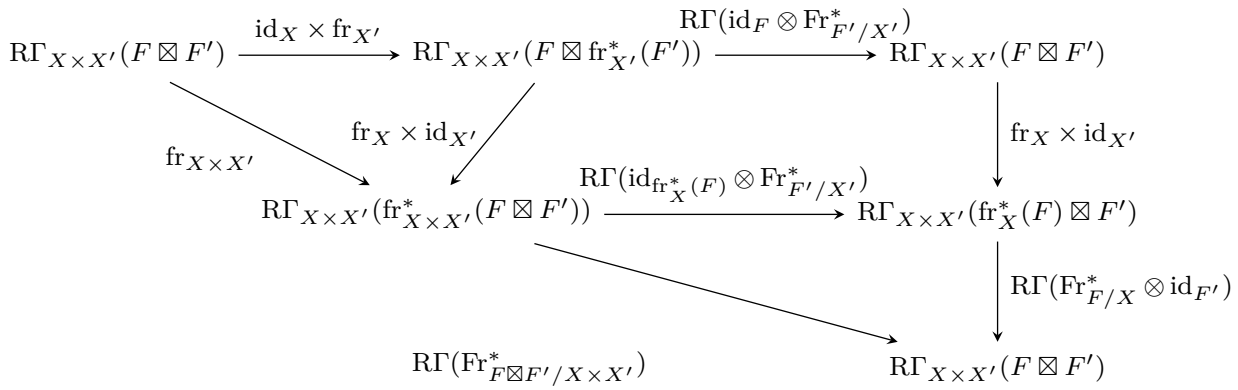
$$(\mathrm{id}_X \times \mathrm{fr}_{X'},\ \mathrm{id}_F \otimes \mathrm{Fr}^*_{F'/X'})$$

and by

$$(\mathrm{fr}_X \times \mathrm{id}_{X'},\ \mathrm{Fr}^*_{F/X} \otimes \mathrm{id}_{F'})$$

are inverse isomorphisms of each other.

Denoting these endomorphisms by ψ' and ψ, let us show for example that $\psi \circ \psi' = \mathrm{id}$. This follows from the commutative diagram



which is commutative because

$$\mathrm{fr}_{X\times X'} = (\mathrm{fr}_X \times \mathrm{id}_{X'}) \circ (\mathrm{id}_X \times \mathrm{fr}_{X'})$$

for the upper triangle and because

$$\mathrm{Fr}^*_{F\boxtimes F'/X\times X'} = (\mathrm{Fr}^*_{F/X} \otimes \mathrm{id}_{F'}) \circ (\mathrm{id}_{\mathrm{fr}^*_X F} \otimes \mathrm{Fr}^*_{F'/X'})$$

for the lower triangle, and in which the composite of the two oblique arrows is the identity by proposition 2c). With an analogous diagram exchanging the roles of (X, F) and (X', F'), one obtains $\psi' \circ \psi = \mathrm{id}$.

We shall apply this result to the particular case where $X' = \bar{e} = \mathrm{Spec}(\overline{\mathbb{F}}_p)$ is the spectrum of an algebraic closure $\overline{\mathbb{F}}_p$ of $\mathbb{F}_p$ and where $F' = \Lambda_{\bar{e}}$ is the constant sheaf with fibre Λ. In this case put

$$\overline{X} = X \times_e \bar{e} = X \otimes_{\mathbb{F}_p} \overline{\mathbb{F}}_p, \qquad \overline{F} = F \otimes_\Lambda \Lambda_{\bar{e}},$$

the inverse image of F by the projection $\overline{X} \to X$. The Frobenius endomorphism $\mathrm{fr}_{\bar{e}}$ is identified with the canonical generator

$$f : \lambda \longmapsto \lambda^p \qquad (\lambda \in \overline{\mathbb{F}}_p)$$

of the Galois group

$$\pi_e = \mathrm{Gal}(\overline{\mathbb{F}}_p/\mathbb{F}_p),$$

where f determines an isomorphism $\widehat{\mathbb{Z}} \simeq \pi_e$, and

$$\mathrm{Fr}^*_{\Lambda_{\bar{e}}/\bar{e}} = \mathrm{id}_{\Lambda_{\bar{e}}}$$

since $\Lambda_{\bar{e}}$ is a constant sheaf. Put

$$\overline{\mathrm{fr}}_X = \mathrm{fr}_X \times \mathrm{id}_{\bar{e}},$$

the inverse image of fr_X by $\overline{X} \to X$,

$$f_X = \mathrm{id}_X \times \mathrm{fr}_{\bar{e}},$$

the automorphism of $\overline{X}$ defined by f by transport of structure, and

$$\overline{\mathrm{Fr}}^*_{F/X} = \mathrm{Fr}^*_{F/X} \otimes \mathrm{id}_{\Lambda_{\bar{e}}},$$

the inverse image of $\mathrm{Fr}^*_{F/X}$ by $\overline{X} \to X$. We may write

$$\mathrm{fr}_{\overline{X}} = \overline{\mathrm{fr}}_X \circ f_X = f_X \circ \overline{\mathrm{fr}}_X, \qquad \mathrm{Fr}^*_{\overline{F}/\overline{X}} = \overline{\mathrm{Fr}}^*_{F/X}.$$

The corollary of Proposition 3 shows that the endomorphism of $\mathrm{R}\Gamma_{\overline{X}}(\overline{F})$ defined by the pair $(\overline{\mathrm{fr}}_X, \overline{\mathrm{Fr}}^*_{F/X})$ is the inverse of the automorphism defined by f_X. We shall say that $(\overline{\mathrm{fr}}_X, \overline{\mathrm{Fr}}^*_{F/X})$ is the geometric Frobenius correspondence; it is the inverse image by $\overline{X} \to X$ of the Frobenius correspondence on (X, F). Denote by

$$\mathrm{fr}_{\mathrm{R}\Gamma_{\overline{X}}(\overline{F})}$$

the automorphism of $\mathrm{R}\Gamma_{\overline{X}}(\overline{F})$ which it defines. The arithmetic Frobenius operation, coming by transport of structure from $f \in \pi_e$, is its inverse.

§ 3. The L-function

1. Definition

Let p be a prime number; consider a prime number $\ell \neq p$ and a finite extension Ω of $\mathbb{Q}_\ell$. To every pair (X, F) consisting of a scheme X of finite type over $e = \mathrm{Spec}(\mathbb{F}_p)$ and a constructible Ω-sheaf F on X, we shall associate a formal series

$$L_F \in \Omega[[t]],$$

with constant term 1.

First consider the special case where $X = e$; let $\bar{\mathbb{F}}_p$ be an algebraic closure of $\mathbb{F}_p$ and let $\bar{e} = \mathrm{Spec}(\bar{\mathbb{F}}_p)$. The sheaf F is entirely determined by its fibre $F_{\bar{e}}$, regarded as a finite-dimensional Ω-vector space on which the Galois group

$$\pi_e = \mathrm{Gal}(\bar{\mathbb{F}}_p/\mathbb{F}_p)$$

acts continuously. Since π_e is topologically generated by the Frobenius element

$$f : \lambda \longmapsto \lambda^p \qquad (\lambda \in \bar{\mathbb{F}}_p),$$

the data of the sheaf F is equivalent to that of the vector space $F_{\bar{e}}$ endowed with an automorphism $f_{F_{\bar{e}}}$ which is "topologically unipotent", that is, whose k-th power tends to the identity in the analytic group $\mathrm{Aut}(F_{\bar{e}})$ as k tends "multiplicatively" to infinity. We set

$$L_F(t) = 1/\det(1 - f_{F_{\bar{e}}}^{-1} t) \in \Omega[[t]].$$

Now suppose that $X = \mathrm{Spec}(\mathbb{F}_q)$, with $q = p^d$ (d an integer ≥ 1). Let $\bar{x}$ be a geometric point of X, defined by an embedding of $\mathbb{F}_q$ into $\bar{\mathbb{F}}_p$; the Galois group

$$\pi_x = \mathrm{Gal}(\bar{\mathbb{F}}_p/\mathbb{F}_q)$$

is identified with the subgroup of π_e topologically generated by f^d. Thus the data of the sheaf F is equivalent to that of its fibre $F_{\bar{x}}$, a finite-dimensional vector space over Ω, endowed with a topologically unipotent automorphism $(f^d)_{F_{\bar{x}}}$, which we write as $f^d_{F_{\bar{x}}}$ for simplicity. Let g be the unique morphism from X to e; the direct image $g_*(F)$ is likewise defined by its fibre $(g_*F)_{\bar{e}}$ with the operations of π_e, which is computed as an "induced module"

$$(g_*F)_{\bar{e}} \simeq F_{\bar{x}} \otimes_{\pi_x} \pi_e.$$

We set

$$L_F(t) = L_{g_*F}(t) = 1/\det(1 - f^{-1}_{(g_*F)_{\bar{e}}} t);$$

an easy determinant calculation shows that this expression is equal to

$$L_F(t) = 1/\det(1 - f^{-d}_{F_{\bar{x}}} t^d).$$

In the general case of a scheme X of finite type over e, endowed with a constructible Ω-sheaf F, define

$$L_F = \prod_{x \in X^0} L_{F_x},$$

where X^0 denotes the set of closed points of X; we shall see that this product is multipliable in $\Omega[[t]]$. Indeed, let us make it explicit by introducing, for each $x \in X^0$, a geometric point $\bar{x}$ of X localized at x, defined by an embedding of the residue field $k(x)$ into $\bar{\mathbb{F}}_p$, and by setting

$$d(x) = [k(x) : \mathbb{F}_p]$$

(the degree of x). With this notation

$$L_{F_x}(t) = 1/\det(1 - f_{F_{\bar{x}}}^{-d(x)} t^{d(x)}) = 1 + \mathrm{Tr}(f_{F_{\bar{x}}}^{-d(x)}) t^{d(x)} + \cdots .$$

Since for every integer n the set of points $x \in X^0$ such that $d(x) \leq n$ is finite, it follows that the family $(L_{F_x})_{x \in X^0}$ is multipliable in $\Omega[[t]]$. Thus the L-function of (X, F) is

$$L_F(t) = \prod_{x \in X^0} 1/\det(1 - f_{F_{\bar{x}}}^{-d(x)} t^{d(x)}).$$

The first formal properties of the L-function are collected in the following statement.

Proposition 1.

a) Multiplicativity in F. Let

$$0 \longrightarrow F' \longrightarrow F \longrightarrow F'' \longrightarrow 0$$

be an exact sequence of constructible Ω-sheaves on X; then

$$L_F = L_{F'} L_{F''}.$$

b) Let Y be a closed subscheme of X and let $U = X - Y$ be its open complement. Then

$$L_F = L_{F|U}\, L_{F|Y}$$

for every constructible Ω-sheaf F.

c) Let $X \to S$ be a morphism of schemes of finite type over $\mathbb{F}_p$, and let F be a constructible Ω-sheaf on X; then

$$L_F = \prod_{s \in S^0} L_{F|X_s}.$$

Assertion a) is clear; b) follows from $X^0 = U^0 \cup Y^0$ as a disjoint union, and c) follows from

$$X^0 = \coprod_{s \in S^0} X_s^0$$

using associativity of multipliable infinite products. These formulas on closed points are valid because the image of a closed point under a morphism of preschemes of finite type over $\mathbb{F}_p$ is again a closed point.

2. Statement of the rationality theorem and reduction to the case of a curve

Theorem. Let X be a scheme of finite type over $\mathbb{F}_p$, of dimension n, let $g : X \to e$ be its structural morphism, and let F be a constructible Ω-sheaf on X. Then

$$L_F = \prod_{i=0}^{2n} (L_{R^i_! g(F)})^{(-1)^i}. \tag{1}$$

In this statement the $R^i_! g(F)$ are the higher direct images with proper support, in the sense of ℓ-adic cohomology. We put

$$H^i_!(\bar{X}, \bar{F}) = R^i_! \bar{g}(\bar{F}) = R^i_! g(F)_{\bar{e}}$$

(by the base-change theorem), where $\bar{X}$, $\bar{F}$, and $\bar{g}$ are obtained from X, F, and g by the base change $\bar{e} \to e$, with $\bar{e}$ the spectrum of an algebraic closure of $\mathbb{F}_p$. With this notation, by no. 1,

$$L_{R^i_! g(F)}(t) = 1/\det(1 - f^{-1}_{H^i_!(\bar{X},\bar{F})} t) = L_{f^{-1}_{H^i_!(\bar{X},\bar{F})}}(t),$$

where $L_u(t) = 1/\det(1-ut)$ for every endomorphism u of a finite-dimensional vector space, according to the formalism developed in an earlier exposé.

More generally, consider a morphism $u : X \to Y$ of schemes of finite type over $\mathbb{F}_p$ and a constructible Ω-sheaf F on X. Let $(P_{F,u})$ denote the following property:

$$(P_{F,u}): \qquad L_F = \prod_i (L_{R^i_! u(F)})^{(-1)^i}.$$

The theorem for the pair (X, F) is precisely $(P_{F,g})$, where $g : X \to e$ is the structural morphism of X. We shall reduce it to the case where X is the projective line by means of a few lemmas.

Lemma 1. Let $u : X \to Y$ be a morphism of schemes of finite type over $\mathbb{F}_p$, and let F be a constructible Ω-sheaf. If $(P_{F|X_y,u_y})$ is true for every $y \in Y^0$, then $(P_{F,u})$ is true.

Indeed,

$$L_F = \prod_{y \in Y^0} L_{F|X_y}$$

(no. 1, Proposition 1c), and hence

$$= \prod_{y \in Y^0} \prod_i (L_{R^i_! u_y(F|X_y)})^{(-1)^i}$$

using $(P_{F|X_y,u_y})$; but

$$R^i_! u_y(F|X_y) \simeq R^i_! u(F)_y$$

by the base-change theorem, which gives

$$L_F = \prod_i \left(\prod_{y \in Y^0} L_{(R^i_! u(F))_y} \right)^{(-1)^i} = \prod_i (L_{R^i_! u(F)})^{(-1)^i}$$

by the definition of the L-function on Y.

Corollary. Let $u : X \to Y$ be a finite morphism of schemes of finite type over $\mathbb{F}_p$, and let F be a constructible Ω-sheaf on X. The property $(P_{F,u})$ is true.

The lemma allows us to reduce to the case where Y is punctual: $Y = \mathrm{Spec}(\mathbb{F}_q)$. Then X is finite and

$$u_*(F) \simeq \bigoplus_{x \in X} u_*(F_x).$$

To establish the formula $(P_{F,u})$, namely $L_F = L_{u_*F}$, one is therefore reduced to the case where X itself is punctual: $X = \mathrm{Spec}(\mathbb{F}_{q'})$. Let $g : X \to e$ and $h : Y \to e$ be the structural morphisms. By definition (no. 1),

$$L_F = L_{g_*F} = L_{h_*u_*F} = L_{u_*F},$$

since $g = h \circ u$.

Lemma 2. Let $u : X \to Y$ and $v : Y \to Z$ be morphisms of schemes of finite type over $\mathbb{F}_p$, and let F be a constructible Ω-sheaf on X. If the properties $(P_{F,u})$ and $(P_{R^i_!u(F),v})$ for all i are true, then $(P_{F,v\circ u})$ is true.

Indeed,

$$L_F = \prod_i (L_{R^i_!u(F)})^{(-1)^i} = \prod_i \prod_j (L_{R^j_!v(R^i_!u(F))})^{(-1)^i(-1)^j}$$

$$= \prod_{i,j} (L_{R^j_!v(R^i_!u(F))})^{(-1)^{i+j}}$$

by $(P_{F,u})$ and $(P_{R^i_!u(F),v})$. The Leray spectral sequence

$$R^j_!v(R^i_!u(F)) \Longrightarrow R^k_!(v \circ u)(F)$$

and the multiplicativity of L_F with respect to F (no. 1, Proposition 1a) finally give

$$L_F = \prod_k (L_{R^k_!(v\circ u)(F)})^{(-1)^k},$$

as required.

Lemma 3. Let X be a scheme of finite type over $\mathbb{F}_p$, and let $g : X \to e$ be its structural morphism.

a) Let F be a constructible Ω-sheaf on X, let Y be a closed subscheme of X, and let $U = X - Y$ be the open complement. If the theorem is true for two of the three pairs (X, F), $(Y, F|Y)$, $(U, F|U)$, then it is true for the third.

b) Let

$$0 \longrightarrow F' \longrightarrow F \longrightarrow F'' \longrightarrow 0$$

be an exact sequence of constructible Ω-sheaves on X. If the theorem is true for two of the three pairs (X, F'), (X, F), (X, F''), then it is true for the third.

We shall use only a), but we also give b) for symmetry. The proofs of a) and b) are analogous; let us prove a), for example. The exact sequence

$$\cdots \longrightarrow R^i_!g_U(F|U) \longrightarrow R^i_!g(F) \longrightarrow R^i_!g_Y(F|Y) \longrightarrow R^{i+1}_!g_U(F|U) \longrightarrow \cdots$$

and Proposition 1a) (no. 1) give

$$\prod_i (L_{R^i_! g(F)})^{(-1)^i} = \prod_i (L_{R^i_! g_U(F|U)}\, L_{R^i_! g_Y(F|Y)})^{(-1)^i},$$

and Proposition 1b) (no. 1) then allows one to conclude.

The arguments of Lemmas 1, 2, and 3 may be summarized by saying that, by Proposition 1 of no. 1, the function L_F has formal properties analogous to those of cohomology with proper support.

We now use the preceding lemmas to reduce to the case where X is the projective line.

First reduction: by noetherian induction one may construct a partition $(U_j)_{1\leq j\leq r}$ of X by affine schemes such that U_{j+1} is open in $X - \bigcup_{i=1}^{j} U_i$ for $j = 1, \ldots, r-1$. Suppose that the theorem has been established for every pair (U, G), where U is an affine scheme of finite type over $\mathbb{F}_p$ and G is a constructible Ω-sheaf on U. It is then true for $(U_j, F|U_j)$, $j = 1, \ldots, r$; by Lemma 3a), descending induction on j shows that it is true for $(\bigcup_{i\geq j} U_i, F|\bigcup_{i\geq j} U_i)$, and hence for (X, F), since $X = \bigcup_{i\geq 1} U_i$. It is therefore enough to prove the theorem in the case where X is affine.

Second reduction: suppose X affine of dimension n. There exists a finite morphism $u : X \to \mathbb{E}^n$ from X into numerical space of dimension n. We reason by induction on n. For $n = 0$, X is finite over e and the theorem is true by the corollary to Lemma 1. If $n \geq 1$, suppose the theorem established for affine schemes of dimension $n-1$; let $u : X \to \mathbb{E}^n$ be a finite morphism and let $v : \mathbb{E}^n \to \mathbb{E}^1$ be a projection morphism, defined from an isomorphism $\mathbb{E}^n \simeq \mathbb{E}^1 \times \mathbb{E}^{n-1}$. Composing, one obtains a morphism $w = v \circ u : X \to \mathbb{E}^1$ whose fibres are affine schemes of dimension $n-1$. Lemma 1 then shows that the property $(P_{F,w})$ is true by the induction hypothesis. By Lemma 2, it is enough to establish the theorem for the pairs $(\mathbb{E}^1, R^i_! w(F))$. Thus one is reduced to the case where $X = \mathbb{E}^1$ is the affine line.

Third reduction: suppose $X = \mathbb{E}^1$. Let $i : \mathbb{E}^1 \to \mathbb{P}^1$ be the immersion of the affine line into the projective line $\mathbb{P}^1$, and let $Z = \mathbb{P}^1 - i(\mathbb{E}^1)$ be the reduced closed subscheme at the point at infinity of $\mathbb{P}^1$. Since the theorem is true for $(Z, i_!(F)|Z)$, it is equivalent, by Lemma 3a), to establish it for $(\mathbb{E}^1, F)$ or for $(\mathbb{P}^1, i_!(F))$; since i is an open immersion one has $F = i_!(F)|\mathbb{E}^1$.

3. Proof of the theorem

After these reductions, it remains to establish the theorem in the case where X is the projective line. We shall first transform formula (1) of the statement into a Lefschetz-type formula involving traces; this latter formula will be proved in the particular case where X is a projective smooth curve.

Return to formula (1):

$$L_F = \prod_i (L_{R^i_! g(F)})^{(-1)^i} = \frac{P_F^1 \cdots P_F^{2n-1}}{P_F^0 \cdots P_F^{2n}}, \quad \text{where} \quad P_F^i(t) = \det(1 - f^{-1}_{H^i_!(\bar{X},\bar{F})} t).$$

The logarithm of the left-hand side is

$$\sum_{x\in X^0} \sum_{n=1}^{\infty} \operatorname{Tr}(f_{F_{\bar{x}}}^{-nd(x)})\, t^{nd(x)}/n = \sum_{n=1}^{\infty} \left(\sum_{d(x)|n} d(x) \operatorname{Tr}(f_{F_{\bar{x}}}^{-n}) \right) t^n/n,$$

while that of the right-hand side is

$$\sum_{n\geq 1} \left(\sum_i (-1)^i \operatorname{Tr}(f^{-n}_{H^i_!(\bar{X},\bar{F})}) \right) t^n/n.$$

Comparing the coefficients of t^n/n, one sees that it is necessary to establish

$$\sum_{d(x)|n} d(x)\,\mathrm{Tr}(f_{F_{\bar{x}}}^{-n}) = \sum_i (-1)^i\,\mathrm{Tr}(f_{H_!^i(\bar{X},\bar{F})}^{-n}) \tag{2}$$

for all $n \geq 1$; these calculations are legitimate because the field Ω has characteristic zero.

Transform formula (2) further by supposing that X is proper, which allows us to write ordinary cohomology instead of cohomology with proper support. Recall that the category of $\mathbb{Q}_\ell$-sheaves on X is a category of fractions of the category of ℓ-adic sheaves. By abuse of notation, we shall henceforth denote by $F = (F_\nu)_{\nu\in\mathbb{N}}$ the ℓ-adic sheaf[31] on X corresponding to the $\mathbb{Q}_\ell$-sheaf underlying F. Then $\bar{F} = (\bar{F}_\nu)$ and the Frobenius morphisms $\overline{\mathrm{Fr}}^*_{F_\nu/X}$ define a morphism of ℓ-adic sheaves

$$\overline{\mathrm{Fr}}^*_{F/X} : \mathrm{fr}_X^*(\bar{F}) \longrightarrow \bar{F},$$

hence an ℓ-adic correspondence on $(\bar{X}, \bar{F})$. For every integer ν, the endomorphism $\mathrm{fr}_{R\Gamma_{\bar{X}}(\bar{F}_\nu)}$ defined by $(\bar{\mathrm{fr}}_X, \overline{\mathrm{Fr}}^*_{F_\nu/X})$ is the inverse of $f_{R\Gamma_{\bar{X}}(\bar{F})}$ (§2, no. 3, Corollary to Proposition 3). Using the definition of ℓ-adic cohomology, it follows that the endomorphism $\mathrm{fr}_{H^i(\bar{X},\bar{F})}$ of $H^i(\bar{X},\bar{F})$ defined by $(\bar{\mathrm{fr}}_X, \overline{\mathrm{Fr}}^*_{F/X})$ is the inverse of $f_{H^i(\bar{X},\bar{F})}$; thus

$$f_{H^i(\bar{X},\bar{F})}^{-n} = \mathrm{fr}_{H^i(\bar{X},\bar{F})}^n$$

for every $n \geq 1$ and every i.

Apply this result in the particular case where $X = x = \mathrm{Spec}(\mathbb{F}_q)$ $(q = p^d)$ is reduced to a point whose degree d divides n. We obtain

$$f_{F_{\bar{x}}}^{-n} = \mathrm{fr}_{F_{\bar{x}}}^n = (\mathrm{Fr}^*_{F_{\bar{x}}/\bar{x}})^n$$

($\bar{x}$ is the geometric point defined by an embedding of $\mathbb{F}_q$ into $\bar{\mathbb{F}}_p$).

On the other hand, $\bar{\mathrm{fr}}_X$ and f_X act in inverse ways on the points of $\bar{X}$. It follows that the projection $\bar{X} \to X$ establishes a bijective correspondence between the set of closed points of degree d of X and the set of d-element orbits of $\bar{\mathrm{fr}}_X$ acting on $\bar{X}$. Noting that the set $\bar{X}^{\bar{\mathrm{fr}}_X^n}$ of points of $\bar{X}$ fixed by $\bar{\mathrm{fr}}_X^n$ is the union of the orbits of $\bar{\mathrm{fr}}_X$ whose cardinality divides n, one can rewrite (2) in the "geometric" form

$$\sum_{\bar{x}\in\bar{X}^{\bar{\mathrm{fr}}_X^n}} \mathrm{Tr}(\mathrm{fr}_{F_{\bar{x}}}^n) = \sum_i (-1)^i\,\mathrm{Tr}(\mathrm{fr}_{H^i(\bar{X},\bar{F})}^n). \tag{2'}$$

This is a Lefschetz-type formula on the scheme $\bar{X}$ endowed with the sheaf $\bar{F}$ and the correspondence $(\bar{\mathrm{fr}}_X, \overline{\mathrm{Fr}}^*_{F/X})$.

To lighten notation, we shall henceforth write X, F, h, and h_F instead of $\bar{X}$, $\bar{F}$, $\bar{\mathrm{fr}}_X^n$, and $(\overline{\mathrm{Fr}}^*_{F/X})^n$; since X and F will no longer appear in their former sense, no confusion can arise. We shall suppose that X is a smooth projective curve over $k = \bar{\mathbb{F}}_p$. The fixed points of h on X all have multiplicity 1: indeed, h acts by $T \mapsto T^{p^n}$ on the completed local ring of a fixed point, where T is a uniformizer. The theorem will follow from the following result.

Proposition 2. Let X be a smooth projective curve over an algebraically closed field k of characteristic p, let F be a constructible ℓ-adic sheaf on X_{et} (with ℓ a prime number distinct from p),

[31] To simplify the notation, for the remainder of the proof we shall suppose that $\Omega = \mathbb{Q}_\ell$. In the general case, one would have to replace $\mathbb{Z}_\ell$ by the normal closure of $\mathbb{Z}_\ell$ in Ω. (Details left to the reader.)

let h be an endomorphism of X whose fixed points all have multiplicity 1, and let $h_F : h^*(F) \to F$ be a morphism of sheaves. The following formula, where $h_{H^i(X,F)}$ denotes the endomorphism of $H^i(X, F)$ defined by (h, h_F), is true:

$$\sum_{x \in X^h} \mathrm{Tr}((h_F)_x) = \sum_i (-1)^i \,\mathrm{Tr}(h_{H^i(X,F)}). \tag{2"}$$

In this seminar, an analogous Lefschetz formula has been established for a constructible torsion sheaf F_ν, annihilated by $\ell^{\nu+1}$ on the curve X, endowed with a morphism $h_{F_\nu} : h^*(F_\nu) \to F_\nu$. It is written

$$\sum_{x \in X^h} \mathrm{Tr}((h_{F_\nu})_x) = \mathrm{Tr}^*\, h_{R\Gamma_X(F_\nu)}, \tag{3}$$

where both sides belong to $\mathbb{Z}/\ell^{\nu+1}\mathbb{Z}$.

Suppose that the ℓ-adic sheaf in the statement is written as $F = (F_\nu)_{\nu \in \mathbb{N}}$, with F annihilated by $\ell^{\nu+1}$. For each ν we may write formula $(3)_\nu$, and one sees that the left-hand sides of these formulas, as ν varies, are the components of an ℓ-adic integer which is precisely the left-hand side of formula (2") to be proved. It remains to establish that the right-hand sides of the formulas $(3)_\nu$ define, as ν varies, an ℓ-adic integer equal to

$$\sum_i (-1)^i \,\mathrm{Tr}(h_{H^i(X,F)}), \quad \text{where} \quad H^i(X, F) = \varprojlim_\nu H^i(R\Gamma_X(F_\nu)).$$

This follows from purely algebraic lemmas that we shall now prove to finish.

Consider a projective system $(K_\nu)_{\nu \in \mathbb{N}}$ of perfect complexes, with $K_\nu \in D_{\mathrm{parf}}(\mathbb{Z}/\ell^{\nu+1}\mathbb{Z})$, such that for each ν the transition morphism $K_{\nu+1} \to K_\nu$ is isomorphic, in the sense of derived categories, to the canonical morphism

$$K_{\nu+1} \to K_{\nu+1}/\ell^{\nu+1} K_{\nu+1}.$$

Suppose each complex K_ν is endowed with an endomorphism $h_\nu \in \mathrm{Fl}(D_{\mathrm{parf}}(\mathbb{Z}/\ell^{\nu+1}\mathbb{Z}))$, so that $(h_\nu)_{\nu \in \mathbb{N}}$ is compatible with the transition morphisms, thereby defining an endomorphism of the projective system (K_ν). In the application to the proof of Proposition 2 one takes

$$K_\nu = R\Gamma_X(F_\nu), \qquad h_\nu = h_{R\Gamma_X(F_\nu)};$$

the condition on transition morphisms follows by the "Künneth formula" from the analogous condition verified by the transition morphisms of the ℓ-adic projective system (F_ν).

We propose to find a projective system $(K'_\nu)_{\nu \in \mathbb{N}}$, where K'_ν is a complex of free $(\mathbb{Z}/\ell^{\nu+1}\mathbb{Z})$-modules of finite type, zero outside an interval of degrees $[a, b]$ independent of ν, and endowed with an endomorphism of complexes $h'_\nu : K'_\nu \to K'_\nu$, such that the following conditions are satisfied:

1) the transition morphism $K'_{\nu+1} \to K'_\nu$ is isomorphic, as a morphism of complexes, to

$$K'_{\nu+1} \to K'_{\nu+1}/\ell^{\nu+1} K'_{\nu+1}$$

for every $\nu \in \mathbb{N}$;

2) $(h'_\nu)_{\nu \in \mathbb{N}}$ is compatible with the transition morphisms;

3) (K'_ν, h'_ν) is isomorphic to (K_ν, h_ν) in $D_{\mathrm{parf}}(\mathbb{Z}/\ell^{\nu+1}\mathbb{Z})$ for every ν, these isomorphisms being choosable so as to be compatible with the transition morphisms of (K'_ν) and (K_ν).

Assuming the construction of the systems (K'_ν) and (h'_ν), we may write

$$\operatorname{Tr}^*(h_\nu) = \operatorname{Tr}^*(h'_\nu) = \sum_i (-1)^i \operatorname{Tr}(h'^i_\nu)$$

for every $\nu \in \mathbb{N}$. Let

$$K' = \varprojlim_\nu K'_\nu, \qquad h' = \varprojlim_\nu h'_\nu$$

be the induced endomorphism of K'. Then $(\operatorname{Tr}^*(h_\nu))_\nu$ is an ℓ-adic integer equal to $\sum_i (-1)^i \operatorname{Tr}(h'^i)$. Moreover, the projective system (K'_ν) satisfies the Mittag-Leffler condition, and so does the system $(H^{i-1}(K'_\nu))_\nu$ for every i; it follows that

$$H^i(K') \simeq \varprojlim_\nu H^i(K'_\nu)$$

for every i (EGA 0_{III} 13.2.3). In the case of interest to us, where $K_\nu = R\Gamma_X(F_\nu)$ and $h_\nu = h_{R\Gamma_X(F_\nu)}$, $H^i(K')$ is identified with $H^i(X,F)$, and the endomorphism of $H^i(K')$ defined by h' is identified with $h_{H^i(X,F)}$. Consequently

$$\sum_i (-1)^i \operatorname{Tr}(h'^i) = \sum_i (-1)^i \operatorname{Tr}(h_{H^i(X,F)}),$$

and formula (2") in the statement is thereby proved.

The existence of the systems (K'_ν) and (h'_ν) rests on two lemmas, in which we consider a commutative ring A, an ideal I of A, and the functor

$$T : L \longmapsto L \otimes_A A_0$$

where L is a complex of A-modules bounded on the right, with $A_0 = A/I$.

Lemma 1. Suppose that the ideal I is nilpotent. Consider a complex $L \in D^-(A)$ flat in every degree, a complex $M \in D^-(A_0)$ projective in every degree, and an isomorphism

$$u : T(L) \xrightarrow{\sim} M$$

in $D^-(A_0)$. There exist a complex L' of A-modules, bounded on the right and projective in every degree, an isomorphism

$$v : L \xrightarrow{\sim} L'$$

in $D^-(A)$, and an isomorphism of complexes

$$w : T(L') \xrightarrow{\sim} M,$$

such that $u = w \circ T(v)$ in $D^-(A_0)$.

Remark. If M is assumed to be free, respectively of finite type, in every degree, then the complex L' is also free, respectively of finite type, in every degree. Indeed, if a flat A-module N is such that $T(N)$ is free, respectively of finite type, it is easy to show that N is free, respectively of finite type (Bourbaki, Commutative Algebra, Chap. II, §3, Prop. 5). Note the corollary: let $L \in \operatorname{ob} D^-(A)$ be such that $L \overset{\mathrm{L}}{\otimes}_A A_0$ is a pseudo-coherent, respectively perfect, complex of A_0-modules, that is, isomorphic in $D^-(A)$ to a complex bounded above, respectively bounded, and projective of finite type in every degree. Then L is a pseudo-coherent, respectively perfect, complex of A-modules.

Lemma 2. Consider a complex L of A-modules bounded on the right, projective in every degree, endowed with an endomorphism φ, and an endomorphism φ_0 of $M = T(L)$ coinciding with $T(\varphi)$ in the sense of the derived category $D^-(A_0)$. There exists an endomorphism φ' of L which coincides with φ in the sense of $D^-(A)$ and satisfies $T(\varphi') = \varphi_0$.

Before proving these lemmas, let us indicate how they are applied to prove the existence of the systems (K'_ν) and (h'_ν). We argue by induction on ν, supposing that $K'_0, h'_0, \ldots, K'_{\nu-1}, h'_{\nu-1}$ have already been constructed. Apply the lemmas with

$$A = \mathbb{Z}/\ell^{\nu+1}\mathbb{Z}, \qquad I = \ell^\nu\mathbb{Z}/\ell^{\nu+1}\mathbb{Z}$$

so that $I^2 = 0$, and

$$A_0 = \mathbb{Z}/\ell^\nu\mathbb{Z}.$$

First take $L = K_\nu$ and $M = K'_{\nu-1}$ in the first lemma. In view of the remark, this gives the existence of $K'_\nu = L'$ with transition morphism $K'_\nu \to K'_{\nu-1}$ given by w, so that condition 1) above is satisfied. The isomorphism v in $D^-(A)$ allows h_ν to be transported to an endomorphism of K' in the sense of $D^-(A)$. We may suppose that the latter comes from an endomorphism of complexes $h''_\nu : K'_\nu \to K'_\nu$. Applying the second lemma with $L = K'_\nu$, $\varphi = h''_\nu$, and $\varphi_0 = h'_{\nu-1}$, we obtain the existence of $h'_\nu : K'_\nu \to K'_\nu$ satisfying condition 2); condition 3) is also satisfied. Note that, with the notation of Lemma 1, if $M^i = 0$ for an index i, then $L'^i = 0$ follows from Nakayama's lemma; the complexes K'_ν are therefore indeed all zero outside one and the same interval of degrees.

To prove Lemmas 1 and 2 we shall need the following result.

Lemma 3.

(i) Let P and Q be A-modules. If P is projective, then for every A_0-linear map $f_0 : T(P) \to T(Q)$ there exists an A-linear map $f : P \to Q$ such that $T(f) = f_0$.

(ii) Suppose that the ideal I is nilpotent. For every projective A_0-module P_0 there exists a projective A-module P such that $T(P) \simeq P_0$. If moreover P' is a flat A-module such that $T(P') \simeq P_0$, then $P' \simeq P$.

Assertion (i) is clear: if u_P (resp. u_Q) denotes the canonical map from P onto $T(P)$ (resp. from Q onto $T(Q)$), then the composite $f_0 \circ u_P$ is an A-linear map from P to $T(Q)$, and u_Q is surjective. Since P is projective, there is a factorization of $f_0 \circ u_P$ through u_Q, namely $f_0 \circ u_P = u_Q \circ f$, where f is an A-linear map from P to Q; then $T(f) = f_0$.

To prove (ii), first observe that the case where P_0 is free is evident, with no hypothesis on the ideal I. The general case, where P_0 is projective, is reduced to this by introducing a free A_0-module L_0 of which P_0 is a direct factor, and a free A-module L such that $T(L) \simeq L_0$. The module P_0 is identified with the image of a projector $e_0 : L_0 \to L_0$, and it remains to see that there exists a projector $e : L \to L$ lifting e_0. This follows from Bourbaki, Commutative Algebra, Chap. III, §4, no. 6, Lemma 2, applied to the sub-A-algebra B of $\mathrm{End}(L)$ generated by an endomorphism of L lifting e_0 (whose existence is ensured by (i)) and to the nilpotent ideal which is the trace on B of the kernel of the canonical homomorphism $\mathrm{End}(L) \to \mathrm{End}(L_0)$. This proves the existence of P in (ii). If moreover P' is as in (ii), then the composite isomorphism $T(P) \simeq P_0 \simeq T(P')$ comes, by (i), from a homomorphism $f : P \to P'$. Since P and P' are flat over A and $T(f)$ is an isomorphism, it follows that $\mathrm{Gr}_I(f)$ is an isomorphism; hence f is an isomorphism, since I is nilpotent. This proves (ii).

Corollary. Suppose the ideal I is nilpotent. For every acyclic complex N_0 of projective A_0-modules, bounded on the right, there exists an acyclic complex N of projective A-modules, bounded on the right, such that $T(N) \simeq N_0$.

The complex N_0, being acyclic, decomposes into short exact sequences

$$0 \longrightarrow Z_0^i \longrightarrow N_0^i \longrightarrow Z_0^{i+1} \longrightarrow 0,$$

where Z_0^i denotes, for each i, the submodule of cycles of N_0^i; moreover $N_0^i = 0$ for all sufficiently large i. By descending induction on i, one sees that the preceding exact sequences are split and that Z_0^i is projective for all i. One lifts N_0 by lifting all these exact sequences step by step, by descending induction on i. It is therefore enough to show that if

$$S_0 : 0 \longrightarrow P_0 \longrightarrow Q_0 \longrightarrow R_0 \longrightarrow 0$$

is an exact sequence of A_0-modules with Q_0 projective, and if R is an A-module such that $T(R) \simeq R_0$, then there exists an exact sequence

$$S : 0 \longrightarrow P \longrightarrow Q \longrightarrow R \longrightarrow 0$$

of A-modules, with Q projective, such that $T(S) \simeq S_0$. Now Q_0 can be lifted to a projective A-module Q by Lemma 3(ii), and $Q_0 \to R_0$ can be lifted to an A-linear map $Q \to R$ by Lemma 3(i). This map is surjective by Nakayama's lemma; one sets $P = \ker(Q \to R)$ to complete the exact sequence S.

Proof of Lemma 2: since $M = T(L)$ is projective in every degree, the hypothesis of the lemma says that $T(\varphi)$ is homotopic to φ_0. Thus there exists a homotopy operator $k_0 = (k_0^i)_i$, with $k_0^i : M^i \to M^{i-1}$, such that

$$T(\varphi) - \varphi_0 = d_0 k_0 + k_0 d_0,$$

where d_0 is the differential of M. By Lemma 3(i), k_0^i lifts to a linear map $k^i : L^i \to L^{i-1}$. This gives a homotopy operator $k = (k^i)_i$ in L. It is enough to set

$$\varphi' = \varphi - kd - dk$$

where d is the differential of L, to verify Lemma 2.

Proof of Lemma 1: after replacing L by a quasi-isomorphic complex if necessary, we may suppose that the complex L, and hence also $T(L)$, is projective in every degree; we shall assume this henceforth. Thus we may suppose that the isomorphism u of $D^-(A_0)$ comes from a quasi-isomorphism $T(L) \to M$, again denoted by u. We shall first reduce to the case where u is surjective. The complex N_0 defined by

$$N_0^i = M^i \oplus M^{i-1}, \quad d^i(x, y) = (d^i x, x - d^{i-1} y)$$

($x \in M^i$, $y \in M^{i-1}$) is visibly acyclic and projective in every degree; an epimorphism of complexes $N_0 \to M$ is defined by the projection $N_0^i \to M^i$ in degree i. The corollary to Lemma 3 allows us to lift N_0 to an acyclic complex N, bounded on the right and projective in every degree. We may then replace L by $L \oplus N$, which is quasi-isomorphic to it, since N is acyclic, and projective in every degree. At the same time, replace u by the quasi-isomorphism

$$T(L \oplus N) = T(L) \oplus N_0 \longrightarrow M$$

defined by u on $T(L)$ and by the epimorphism $N_0 \to M$ on N_0; it is clear that this last quasi-isomorphism is surjective.

Suppose therefore that $u : T(L) \to M$ is a surjective quasi-isomorphism, and let R_0 be its kernel. The complex R_0 is acyclic because u is a quasi-isomorphism, and it is projective in every degree because the exact sequence

$$0 \longrightarrow R_0 \longrightarrow T(L) \longrightarrow M \longrightarrow 0$$

is split, since M is projective in every degree. Hence, by the corollary to Lemma 3, R_0 can be lifted to a complex R of A-modules, bounded on the right, acyclic, and projective in every degree. We now show that the morphism $f_0 : R_0 \to T(L)$ lifts to a morphism of complexes $f : R \to L$. For this, observe that R_0 is homotopically trivial, so that f_0 is homotopic to 0 and can be written

$$f_0 = h_0 d_{R_0} + d_{T(L)} h_0,$$

where $h_0 = (h_0^i)_i$, with $h_0^i : R_0^i \to T(L)^{i-1}$. Lemma 3(i) allows h_0 to be lifted to $h = (h^i)_i$, with $h^i : R^i \to L^{i-1}$, and one sees that

$$f = h d_R + d_L h$$

is a morphism of complexes lifting f_0. A standard lemma (compare SGA 60/61, IV 5.7) then implies that f is injective and that $\operatorname{coker} f = L'$ is flat in every degree. Since

$$T(L') \simeq \operatorname{coker} T(f) = \operatorname{coker} f_0 \simeq M$$

is projective in every degree, it follows, by Lemma 3(ii), that the same is true of L'. On the other hand, the canonical homomorphism $L \to L'$ is a quasi-isomorphism, being surjective with acyclic kernel R; thus L' satisfies the desired conclusion of Lemma 1, q.e.d.

Seminar on Algebraic Geometry of Bois Marie

1966–67

Intersection Theory and the Riemann–Roch Theorem

(SGA 6)

a seminar directed by

P. Berthelot, A. Grothendieck, L. Illusie

with the collaboration of

D. Ferrand, J.-P. Jouanolou, O. Jussila, S. Kleiman, M. Raynaud, J.-P. Serre

Preface

The present edition of *Séminaire de Géométrie Algébrique 6* reproduces, up to minor changes, the first edition, distributed by the I.H.E.S. in the form of mimeographed exposés. The corrections made concern essentially printing errors, except in Exposés I and III, where slight modifications were made by L. Illusie to a few statements which were incorrect in the primitive version. Footnotes have also been added, especially in Exposé XIV by A. Grothendieck, in order to point out recent progress on questions that were still open at the time of the seminar.

Finally, note that Exposé XI, by D. Ferrand, on determinant theory for perfect complexes, was not written up and therefore will not be published; to avoid errors in references, we have left unchanged the numbering of the following exposés.

June 1971

Introduction

The purpose of the present seminar is to develop a global theory of intersections, and a Riemann–Roch formula, for arbitrary schemes. The reader will find a description of the programme of the seminar in Exposé 0. The possibility in principle of proving a Riemann–Roch formula for general regular schemes, along the lines of the well-known Borel–Serre report of 1958, was already clear at that time, at least for a projective morphism. The extension to the general case is less evident; the programme in which it belongs, and which is partly carried out in this seminar, goes back to 1960. As was also the case for the duality theory of coherent sheaves, an essential tool for formulating a satisfactory theory is Verdier's theory of derived categories; familiarity with it is indispensable for understanding the seminar.

Apart from this theory, the study of the seminar requires little more than a general knowledge of the foundations of algebraic geometry as set out in EGA, chapters I, II, III. We shall only occasionally refer to EGA IV, for certain facts concerning flat or smooth morphisms, which for the most part also appear in the first exposés of SGA 1. Finally, to develop some results with the full generality desirable for applications, we sometimes use the notion of a ringed site and of a ringed topos, for which we refer to SGA 4, Exposés I to IV. A reader unfamiliar with the language of sites and topoi may everywhere replace these objects by ordinary topological spaces, the objects of the topos then being replaced by open subsets of these spaces; nevertheless,

we recommend that the reader assimilate the language of topoi, which provides an extremely convenient unifying principle.

The fundamental notion for the theory presented here is that of a perfect complex of modules, together with its various variants, developed in Exposés I, II, III. It seems clear that these notions, also important in other contexts in algebraic geometry, notably for formulas of Lefschetz–Verdier type in cohomology with discrete coefficients (SGA 5) or coherent coefficients, will also have a role to play outside algebraic geometry, especially in the formulation of a complex analytic variant of the Riemann–Roch theorem presented here, or of suitable variants of the Atiyah–Singer index theorem. Some indications in this direction will be given in Exposé II. Unfortunately, at present there is still no statement, even heuristic, which would encompass these two theorems, the first of which remains conjectural for the moment. A new idea seems to be missing, just as one is also missing in algebraic geometry for proving Riemann–Roch beyond projective hypotheses (cf. Exposé XIV, no. 2).

We shall make no use in this seminar of the local theory of intersections, set out in J.-P. Serre, *Algèbre locale. Multiplicités* (Lecture Notes in Mathematics no. 11, Springer), and merely point out here that Serre's course had an evident influence on the genesis of the theory in 1957. Nor shall we use the theory of the Chow ring developed in the Chevalley Seminar of 1958, Exposés 2 and 3 (École Normale Supérieure). That theory is essentially tied to nonsingularity hypotheses, whereas the aim of our seminar is, on the contrary, to develop a theory of intersections on general schemes, and even on general locally ringed topoi. On this matter see the comments in Exposé XIV, nos. 4 and 8, which give the relations between our theory and that of the Chow ring and raise the question of a generalization of the latter. Thus one may say that the seminar presents a coherent and self-contained theory of intersections, but one which is by no means exhaustive of the different points of view useful, indeed indispensable, in intersection theory; consequently it should be complemented by the cited exposés of Serre and Chevalley.

We have appended to the seminar, as an appendix to Exposé 0, Grothendieck's 1957 report, "Classes of sheaves and the Riemann–Roch theorem", which served as the basis for the Borel–Serre seminar at Princeton in the same year and for their already cited article. That report sketches two proofs of the Riemann–Roch theorem for nonsingular quasi-projective varieties. The first, valid for the time being only in characteristic zero but giving, in return, a slightly more precise result in the case of an immersion, has not yet appeared in the literature, apart from the work of Borel–Serre and the present seminar. The report presupposes, of course, none of the other exposés of the seminar, and can even serve, like Exposé 0, as an introduction to the study of the latter, especially for a reader not yet familiar with Borel–Serre. The proof just alluded to applies essentially unchanged to the case of a projective morphism of complex analytic spaces, and will doubtless also apply in arbitrary characteristic once the problem of the operations "exterior powers" in the derived category is solved (cf. Exposé XIV, nos. 1, 2, 3). The absence of a study of this question is no doubt the most serious gap in this seminar, from the point of view we have adopted.

One will notice the absence, in the table of contents of the present seminar, of two of the participants mentioned on the cover page. One of them, J.-P. Jouanolou, took an active part in the technical elaboration of the first part of the seminar, but was prevented from taking part in the oral exposés; in particular, he is responsible for the linear-independence assertion contained in the important statement VI 1.1, giving the structure of the ring K° of classes of locally free modules on a projective bundle, which had previously been proved only under the assumption that the base scheme has an ample invertible module. The other, J.-P. Serre, gave two oral exposés which were logically independent of the rest of the seminar, and therefore preferred to publish them in the form of a separate article (cf. J.-P. Serre, "Grothendieck groups of split reductive group schemes", to appear in *Publications Mathématiques*, no. 34).

As in the other parts of the *Séminaire de Géométrie Algébrique du Bois Marie*, the sigla SGA 1 to SGA 6 refer to the different parts of that seminar; the Roman numeral following the siglum indicates the number of the exposé, and the Arabic numerals following it correspond to the internal numbering of the exposé in question. For internal references within the present seminar the siglum SGA 6 is omitted, and references of the form I 4.9 are used, meaning: Exposé I, statement 4.9. The siglum EGA refers to the *Éléments de Géométrie Algébrique* of J. Dieudonné and A. Grothendieck.

Exposé 0

Outline of a programme for a theory of intersections on general schemes

by A. Grothendieck

The present exposé is introductory in nature, and its reading is not logically indispensable for the study of the seminar. It is addressed more particularly to readers familiar with the provisional version of the Riemann–Roch theorem, as it is presented in the Borel–Serre report or in Grothendieck's report already mentioned in the introduction, cited below as [RRR], and reproduced as an appendix at the end of the present exposé.

1. Reminder on the Riemann–Roch formula

Recall the Riemann–Roch formula for a proper morphism

$$f : X \longrightarrow Y$$

of quasi-projective smooth schemes over a field k, and a coherent sheaf F on X, whose class in the group $K(X)$ of classes of coherent sheaves on X is denoted by $\mathrm{cl}(F)$:

$$\mathrm{Todd}(T_Y)\ \mathrm{ch}_Y\big(f_!(\mathrm{cl}(F))\big) = f_*\big(\mathrm{Todd}(T_X)\ \mathrm{ch}_X(F)\big). \tag{1.1}$$

This formula is valid in $A(Y)\otimes\mathbb{Q}$, where $A(Y)$ is the Chow ring of Y. The f_* on the right hand side is obtained by tensoring with $\mathbb{Q}$ the homomorphism "direct image of cycles"

$$f_* : A(X) \longrightarrow A(Y),$$

while the term on the left is the Euler–Poincaré characteristic of F relative to f:

$$f_!(\mathrm{cl}(F)) = \sum_i (-1)^i\, \mathrm{cl}\big(R^i f_*(F)\big).$$

The symbols ch_X, ch_Y denote the Chern characters on X and on Y, and T_X, T_Y the tangent bundles of X and Y. As is known, $\mathrm{Todd}(-)$ and $\mathrm{ch}(-)$ are universal polynomials with coefficients in $\mathbb{Q}$ in the Chern classes of the argument. Since the constant term of $\mathrm{Todd}(-)$ is 1, it is an invertible element for every value of the argument. Thus, after multiplying by $\mathrm{Todd}(T_Y)^{-1}$, formula (1.1) takes the equivalent form, more convenient for our purposes,

$$\mathrm{ch}_Y\big(f_!(\mathrm{cl}(F))\big) = f_*\big(\mathrm{Todd}(T_f)\ \mathrm{ch}_X(F)\big), \tag{1.2}$$

where

$$T_f = T_X - f^*T_Y \in K(X). \tag{1.3}$$

Thus T_f plays the role of a virtual relative tangent bundle of X over Y. When f is smooth, one simply has $T_f = T_{X/Y}$, whereas when $f : X \to Y$ is an immersion, one obtains

$$T_f = -\check{N}_{X/Y},$$

where $N_{X/Y}$ denotes the normal sheaf of X in Y.

One of the main aims of the seminar is to generalize (1.2) simultaneously in two directions:

a) to get rid of the hypothesis that a base field k exists;

b) to replace the regularity hypotheses on Y, X by a hypothesis of "local regularity" on f.

Finally, along the way, we shall also deal with the following problem:

c) to eliminate the quasi-projectivity hypotheses which, in the absence of a base field, are expressed by the existence of ample invertible modules on X and Y.

2. Removing the base field

Let us first examine generalization a), while retaining the hypotheses of regularity and of the existence of ample invertible modules on X and on Y.

The definitions of $K(X)$, $K(Y)$ and of the homomorphism $f_! : K(X) \to K(Y)$ then present no new problem, thanks to the fact that X and Y are regular. The most natural way to give

a meaning to (1.2) would seem to consist in defining Chow rings $A(X), A(Y)$ and a group homomorphism

$$f_* : A(X) \longrightarrow A(Y),$$

in establishing a theory of Chern classes, giving maps

$$c_i : K(X) \longrightarrow A(X),$$

and similarly for Y, and finally in describing an element, the virtual relative tangent bundle,

$$T_f \in K(X).$$

2.1

For the latter, a definition presents itself rather evidently. One uses the fact that the morphism f, thanks to the hypothesis that ample invertible modules exist on X and on Y, may be factored as

$$X \xrightarrow{i} X' \xrightarrow{f'} Y,$$

where i is a closed immersion and f' is smooth; for example, one may take $X' = \mathbb{P}^r_Y$ for suitable r. One then sets

$$T_f = i^* T_{X'/Y} - \check{N}_{X/X'} \in K(X), \tag{2.1}$$

where $\Omega^1_{X'/Y}$ is the locally free module of relative 1-differentials of X' over Y, or the relative cotangent module of X' over Y, and $N_{X/X'}$ is the conormal module of X in X', by definition equal to J/J^2, where J is the ideal on X' defining X. The regularity hypotheses on X and X' also imply that $N_{X/X'}$ is locally free. Finally, $\check{N}$ denotes the dual of N. One verifies without difficulty, in Exposé VIII, that the element T_f defined by (2.1) is independent of the chosen factorization of f.

2.2

As for a definition, under the conditions considered, of a Chow ring and a corresponding theory of Chern classes, although it is plausible that such a theory should be developable on the model of smooth varieties over a field, it seems that this work has not been done at the present time. We shall therefore adopt another viewpoint, by directly defining a ring which replaces the Chow ring, and whose tensor product with $\mathbb{Q}$ is indeed isomorphic to $A(X) \otimes \mathbb{Q}$ in the classical case.

A first natural filtration of $K(X)$, the one considered in [RRR], is the topological filtration by the codimension of the support of coherent sheaves: $\mathrm{Fil}^i K(X)$ is generated by the $\mathrm{cl}(F)$ with F coherent and $\mathrm{codim}(\mathrm{Supp}\, F, X) \geq i$. A first question is the compatibility of this filtration with the multiplicative structure of $K(X)$. In [RRR], this compatibility is obtained, for X smooth over a field, by means of Chow's moving lemma. Assuming this assertion, one obtains a graded ring $\mathrm{Gr}_{\mathrm{top}}(X)$ and a canonical surjective homomorphism

$$\varphi : A(X) \longrightarrow \mathrm{Gr}_{\mathrm{top}}(X),$$

sending the class of a prime cycle Z to $\mathrm{cl}(\mathcal{O}_Z)$; it then turns out, Exposé XIV 4.2, that the kernel is a torsion subgroup. Moreover, [RRR] shows how the images in $\mathrm{Gr}_{\mathrm{top}}(X)$ of the Chern classes $c_i(F)$ can be computed directly in terms of $\mathrm{cl}(F) \in K(X)$ and the exterior-power operations λ^i in $K(X)$.

This shows that, for a noetherian regular scheme X endowed with an ample invertible module, the ring $\mathrm{Gr}_{\mathrm{top}}(X)$ is a convenient substitute for the hypothetical Chow ring $A(X)$. It also has

the advantage over the latter that certain computations of [RRR], leading to important formulas in this ring, are performed directly in it–formulas which, even for X projective and smooth over a field, have not at present been established in $A(X)$ itself (Exp. XIV, 4.3 and 6.4). To justify this viewpoint completely, however, one would have to solve the problem mentioned above of the compatibility of the topological filtration of $K(X)$ with its ring structure, a problem which seems essentially connected with Chow's moving lemma, itself the essential technical ingredient of the theory of the Chow ring which we have claimed to be able to avoid.

2.3

To avoid this problem, one endows $K(X)$ with a second filtration, finer than the topological filtration, and describable in purely algebraic terms from the structure of $K(X)$ as an augmented λ-ring. The definition of this filtration is suggested by the expression given in [RRR] for the Chern classes of an element $x \in K(X)$ in $\mathrm{Gr}_{\mathrm{top}}(X)$:

$$c_i(x) = \gamma^i(x - \epsilon(x)) \mod \mathrm{Fil}^{i+1} K(X), \tag{2.3}$$

where γ^i denotes a certain linear combination of the λ^j $(j \leq i)$, made explicit in loc. cit., and where ϵ is the augmentation. One shows that $\gamma^i(x - \epsilon(x))$ is indeed of topological filtration at least i, which gives meaning to formula (2.3). One then defines the λ-filtration of $K(X)$ by the ideals $\mathrm{Fil}^i_\lambda K(X)$, where $\mathrm{Fil}^i_\lambda K(X)$ consists of finite sums of expressions of the form

$$\gamma^{i_1}(x_1 - \epsilon(x_1)) \cdots \gamma^{i_r}(x_r - \epsilon(x_r)), \qquad i_1 + \cdots + i_r \geq i.$$

The associated graded ring for this filtration will be denoted $\mathrm{Gr}^\bullet(X)$; it is this ring which will replace the Chow ring of X in the seminar. In the case under consideration here, one can moreover show that the canonical homomorphism

$$\mathrm{Gr}^\bullet(X) \longrightarrow \mathrm{Gr}_{\mathrm{top}}(X) \tag{2.4}$$

is an isomorphism modulo torsion, justifying the viewpoint that, after tensoring with $\mathbb{Q}$, this ring can play exactly the same role as the Chow ring tensored with $\mathbb{Q}$. On the other hand, exactly what was needed has been done so that formula (2.3), with $\mathrm{Fil}_{\mathrm{top}}$ replaced by Fil_λ, defines a theory of Chern classes with values in $\mathrm{Gr}^\bullet(X)$; the Chern classes in $\mathrm{Gr}_{\mathrm{top}}(X)$ are then deduced by means of the homomorphism (2.4). It is shown in Exposé V, using the fact proved in Exposé VI that $K(X)$ is a special λ-ring in the sense of [RRR], that is, a λ-ring in the sense of Exposé V, that this notion of Chern class satisfies all the usual formal properties reviewed in [RRR].

2.4

One should note a very appreciable advantage of the definition of $\mathrm{Gr}^\bullet(X)$ over that of $A(X)$ and $\mathrm{Gr}_{\mathrm{top}}(X)$: it remains meaningful for an absolutely arbitrary scheme X, and more generally for an arbitrary locally ringed topos X. One then takes for $K(X)$ the group of classes constructed from locally free modules on X, which is again an augmented λ-ring, hence equipped with a corresponding filtration and an associated graded $\mathrm{Gr}^\bullet(X)$. The price of this generality, however, is that when one is not willing to neglect torsion phenomena, i.e. to tensor with $\mathbb{Q}$, the properties of $\mathrm{Gr}^\bullet(X)$ are in several respects less satisfactory than those of its two competitors (Exp. XIV no. 4). Thus, assuming again that $f : X \to Y$ is a proper morphism of noetherian regular schemes endowed with ample invertible modules, it is not true in general that the homomorphism

$$f_* : K(X) \longrightarrow K(Y)$$

maps $\mathrm{Fil}^i_\lambda K(X)$ into $\mathrm{Fil}^{i-d}_\lambda K(Y)$, where d is the relative dimension of X over Y, and hence defines, by passage to associated gradeds, a degree $-d$ homomorphism from $\mathrm{Gr}^\bullet(X)$ to $\mathrm{Gr}^\bullet(Y)$. However, Exposé VII proves that this is true after tensoring with $\mathbb{Q}$, so that one obtains a degree $-d$ homomorphism

$$f_* : \mathrm{Gr}^\bullet(X) \otimes \mathbb{Q} \longrightarrow \mathrm{Gr}^\bullet(Y) \otimes \mathbb{Q}, \tag{2.5}$$

which plays the role of the homomorphism "direct image of cycles" $A(X) \to A(Y)$.

Having said this, we see that we possess all the structural elements needed to give meaning to formula (1.2) when the existence of a base field is not postulated, with $f : X \to Y$ a proper morphism of noetherian regular schemes admitting ample invertible modules.

3. The case of general schemes

We now show how one can still give meaning to formula (1.2) when the regularity hypothesis on X, Y is abandoned and replaced by a local hypothesis on the morphism f, to be specified below.

3.1

A first difficulty comes from the fact that the observation which served as the starting point of the theory [RRR], namely that the group $K(X)$ of classes of sheaves on X is the same whether it is defined in terms of coherent sheaves or in terms of locally free sheaves, is essentially tied to the regularity hypothesis on X. For a general scheme X, say noetherian for simplicity, one must distinguish between these two groups; we shall denote them respectively by $K_\bullet(X)$ and $K^\bullet(X)$. The first is covariant in X for proper morphisms, the second contravariant in X for arbitrary morphisms. Notice that $K^\bullet(X)$ is naturally endowed with a ring structure, indeed with an augmented λ-ring structure, whereas $K_\bullet(X)$ no longer has, in general, a ring structure, but only a module structure over $K^\bullet(X)$. The homomorphism $x \mapsto x \cdot \mathrm{cl}(\mathcal{O}_X)$ from $K^\bullet(X)$ to $K_\bullet(X)$ is no longer an isomorphism in general. For our formulation of the generalized Riemann–Roch theorem, we shall work exclusively with $K^\bullet(X)$ and $K^\bullet(Y)$, to the exclusion of $K_\bullet(X)$ and $K_\bullet(Y)$. As noted in 2.3, these augmented λ-rings, equipped with their natural λ-filtration, give rise to graded rings $\mathrm{Gr}^\bullet(X)$, $\mathrm{Gr}^\bullet(Y)$, and to Chern-class homomorphisms

$$c_i : K^\bullet(X) \longrightarrow \mathrm{Gr}^\bullet(X),$$

and similarly for Y. The difficulty, however, lies in defining a direct-image homomorphism

$$f_* : K^\bullet(X) \longrightarrow K^\bullet(Y), \tag{3.1}$$

which can no longer be defined by the naive formula

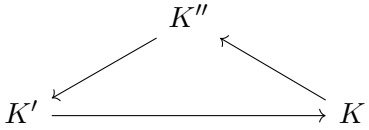
$$f_*(\mathrm{cl}(F)) = \sum_i (-1)^i \,\mathrm{cl}(R^i f_*(F)),$$

because even if F is locally free, the modules $R^i f_*(F)$ are in general no longer locally free, nor even of finite Tor-dimension, and the preceding formula loses its meaning. A solution to this difficulty is furnished by the viewpoint of derived categories. Indeed, whereas the $R^i f_*(F)$ are in general "bad" sheaves, say of infinite Tor-dimension, to which one would not know how to associate a class in $K^\bullet(Y)$, the complex $Rf_*(F)$ on Y, the direct image of F in the sense of derived categories, whose cohomology sheaves are the $R^i f_*(F)$, tends to be excellent. More precisely, suppose that F has finite Tor-dimension over $\mathcal{O}_Y$; this is the case if $\mathcal{O}_X$ has finite Tor-dimension over $\mathcal{O}_Y$ and, in addition, F is locally free. Then one proves (Exp. III) that the complex $Rf_*(F)$ is "perfect", by which we mean here that it has coherent cohomology

sheaves (as was already known in any case) and globally finite Tor-dimension; equivalently, on every affine open U of Y, this complex is isomorphic, in the derived category $D(U)$, to a bounded complex of locally free modules of finite type. From the viewpoint of homological algebra, perfect complexes are "as good as" locally free modules, of which they are the natural generalization. They moreover form a "triangulated subcategory" of the derived category $D(Y)$, i.e. a subcategory stable under the cones (or "mapping cylinders") of morphisms. On the other hand, to every triangulated category C one associates a group $K(C)$ of classes, a natural variant of the construction of the group of classes of an abelian category, by taking the free group generated by the objects of C, modulo the relations

$$\mathrm{cl}(K) - \mathrm{cl}(K') - \mathrm{cl}(K'')$$

for every distinguished triangle



What then replaces the fundamental observation of [RRR] in the present case is the fact that, when the scheme Y admits an ample invertible module, every perfect complex $L_\bullet$ on Y is globally (and not merely locally) isomorphic in $D(Y)$ to a bounded complex L' of locally free modules of finite type (Exp. II). It follows easily (Exp. IV) that the canonical homomorphism

$$K^\bullet(Y) \longrightarrow K(\mathrm{Parf}(Y))$$

is an isomorphism, where $\mathrm{Parf}(Y)$ is the triangulated category of perfect complexes on Y. Thus to every perfect complex $L_\bullet$ on Y one can associate a class

$$\mathrm{cl}(L_\bullet) \in K^\bullet(Y),$$

which is none other than

$$\mathrm{cl}(L_\bullet) = \sum_i (-1)^i \,\mathrm{cl}(L'_i),$$

where L' is as above, so that the L'_i are indeed locally free modules on Y whose classes may be taken in $K^\bullet(Y)$.

3.2

To give a meaning to (1.2), it remains to impose on f a hypothesis making it possible to give a meaning to the homomorphism (2.5), i.e. ensuring that the homomorphism (3.1) just defined is, up to a shift and modulo torsion, compatible with the filtrations of these rings; and finally one must again define an element, the "virtual relative tangent bundle",

$$T_f \in K^\bullet(X).$$

For the latter, returning to the definition proposed in 2.1, one sees that a hypothesis is needed ensuring that, with the notation of loc. cit., the conormal module $N_{X/X'}$ is locally free. The most natural hypothesis to this end is that i be a "regular immersion", i.e. identify X with a subscheme of X' defined by an ideal which locally can be defined by an $\mathcal{O}_{X'}$-regular sequence of sections of $\mathcal{O}_{X'}$. This hypothesis, purely local in nature, in fact does not depend on the choice of the factorization of f into an immersion followed by a smooth morphism (Exp. VIII), and, as above, the same is true for the class T_f defined by formula (2.1). When the hypothesis just

considered is satisfied, the morphism f is called a "locally complete intersection" morphism. Such a morphism is also locally of finite Tor-dimension.

We shall also allow ourselves to omit the word "locally" in this terminology, which cannot cause any confusion.

If f is a locally complete intersection morphism, one introduces a natural notion of "virtual relative dimension" $d(f)$ by the formula

$$d(f)(x) = \dim_x(f^{-1}(f(x))) - \operatorname{codim}_x(X, X').$$

It is an integer-valued function, locally constant at the point $x \in X$, hence constant if X is connected; moreover it does not depend on the choice of the factorization (2.1). When this virtual relative dimension d is constant, when f is proper, and when X and Y admit ample invertible modules, one can prove (Exposé VIII), although this is far from a trivial result, that

$$f_*(\mathrm{Fil}^i K^\bullet(X)_\mathbb{Q}) \subset \mathrm{Fil}^{i-d} K^\bullet(Y)_\mathbb{Q}, \tag{3.4}$$

whence a homomorphism (3.3) of degree $-d$.

3.3

We have therefore assembled all the structural elements needed to give a meaning to formula (1.2) in the case of a proper locally complete intersection morphism of noetherian schemes X, Y, both admitting ample invertible modules. With a little additional care, this formulation in fact retains a meaning independently of any noetherian hypothesis.

In this general form, this Riemann–Roch formula will be proved in Exposé VIII. The reader will observe that the proof given in this seminar combines elements of the two proofs which appear in [RRR] and which were discussed in the Introduction. The need to resort to the methods of the first of these proofs, involving more K-formalism than the second, followed in Borel–Serre, is due to the need for a proof of the inclusion (3.4), a question which did not arise in the more restricted framework of [RRR] and Borel–Serre [2], where one could work with the Chow ring or the ring $\mathrm{Gr}^\bullet_{\mathrm{top}}$. From the second proof, we retain the introduction of the scheme obtained by blowing up Y along X in the case where f is an immersion. This technical artifice will no doubt disappear, and the proof in the case of an immersion will extend to the case where one no longer postulates the existence of an ample invertible module on Y, once the question raised in Exposé XIV, no. 1, concerning the introduction of exterior-power operations in the derived category $D^-(Y)$ has been resolved.

4. Removing the ample invertible module hypothesis

We must finally give a few indications of how one can still give a meaning to (1.2) in the absence of a hypothesis asserting the existence of ample invertible modules on X and Y.

4.1

First note that for an arbitrary scheme X, or more generally an arbitrary locally ringed topos, it seems beyond doubt that the "right" invariant which should replace the ring $K(X)$ of [RRR] is not the ring $K^\bullet(X)$ considered above, defined in terms of locally free modules on X, but rather the group $K(\mathrm{Parf}(X))$ considered in 3.1, defined in terms of perfect complexes on X. We shall denote this group here by $K^\bullet(X)$, and distinguish it from the "naive" group of 3.1, denoted

$K^\bullet_{\text{naive}}(X)$. This point of view is forced by the need to define a direct-image homomorphism (3.1) for a proper morphism

$$f : X \longrightarrow Y$$

of finite Tor-dimension, say between noetherian schemes; the non-noetherian case requires somewhat stronger local finiteness properties on f, cf. Exposé III. With the definition of $K^\bullet(X)$ now adopted, this homomorphism f_* is indeed defined in a trivial way by formula (3.2), where now F is an arbitrary perfect complex on X, which implies that $Rf_*(F)$ is also perfect.

4.2

This new definition of $K^\bullet(X)$ raises, however, a new problem in homological algebra: that of defining a λ-structure on $K^\bullet(X)$ compatible with its natural ring structure coming from tensor product in the derived category. If L and L' are two perfect complexes, then so is their total tensor product $L \otimes^{\mathbf{L}} L'$. More precisely, one would need to define "exterior-power" operations in the derived category $D^-(X)$, transforming perfect complexes into perfect complexes. This question has not yet been clarified at present, and, as was said in the Introduction, it constitutes the most serious gap in the seminar. Once this question is solved, and proceeding as in 2.3, one obtains a natural filtration on $K^\bullet(X)$, allowing one to form the associated graded ring $\mathrm{Gr}^\bullet(X)$, which will play the role of the Chow ring, and to define a theory of Chern classes

$$c_i : K^\bullet(X) \longrightarrow \mathrm{Gr}^i(X).$$

4.3

To give a meaning to formula (1.2) for a proper locally complete intersection morphism

$$f : X \longrightarrow Y$$

of noetherian schemes, one must still include in the statement of this formula the nontrivial inclusions (3.4), where d is the virtual relative dimension, in order to be able to define (3.3); and finally one must define the virtual relative tangent class

$$T_f \in K^\bullet(X).$$

When f admits a factorization (2.1) through an immersion into a relative smooth scheme, the definition of T_f presents no new difficulty. It can moreover be reformulated in that case, in a way more consonant with the spirit of derived categories, by considering the well-known canonical homomorphism

$$N_{X/X'} \longrightarrow \Omega^1_{X'/Y} \otimes_{\mathcal{O}_{X'}} \mathcal{O}_X \tag{4.1}$$

induced by the exterior differential, and the chain complex $L_{X/Y}$ defined from (4.1) by "extending by zeros", with the complex equal in degree 1, respectively 0, to the source, respectively the target, of the homomorphism (4.1). Formula (2.2) then takes the more satisfactory form

$$T_f = \mathrm{cl}(L^\vee_{X/Y}), \tag{4.2}$$

a formula which makes sense in $K^\bullet(X)$ when f is a locally complete intersection morphism, since in that case the complex $L_{X/Y}$ is manifestly perfect. The assertion that T_f is invariant relative to the chosen factorization of f can then be made precise as an invariance assertion for the complex $L_{X/Y}$: up to canonical isomorphism in the derived category $D(X)$, this complex is likewise independent of the chosen factorization (Exposé VIII).

4.4

When $f : X \to Y$ is an arbitrary morphism of schemes, one can still construct a canonical object $L_{X/Y}$ of the derived category $D(X)$, defined up to unique isomorphism, which on each affine open of X lying above an affine open of Y is isomorphic to the complex constructed according to the principle explained in the preceding paragraph. In the general case, however, "smooth" should be replaced by "formally smooth", so that every algebra B over a ring A occurs as a quotient of a formally smooth algebra, for example a polynomial algebra. For such a definition it is not possible to proceed by simple gluing from the affine constructions, since the objects of the derived category $D(X)$ are, essentially, not glueable.

Here is a general construction of $L_{X/Y}$, valid more generally for every morphism

$$f : X \longrightarrow Y$$

of commutatively ringed topoi. Let $B = \mathcal{O}_X$ and $A = f^{-1}\mathcal{O}_Y$, so that A is a ring on the space X and B is an A-algebra. Let $T \to B$ be a homomorphism of sheaves of sets which generates B as an A-algebra, i.e. such that the corresponding homomorphism of A-algebras

$$C = A[T] \longrightarrow B$$

is an epimorphism of sheaves of sets; here $A[T]$ denotes the commutative A-algebra freely generated by T, that is, the sheaf associated with the presheaf

$$U \longmapsto A(U)[T(U)].$$

Let J be the kernel of $C \to B$, and consider, as in 4.3, the chain complex of length 1 defined by the natural homomorphism

$$J/J^2 \longrightarrow \Omega^1_{C/A} \otimes_C B.$$

It is not difficult to see that, up to canonical isomorphism in the category $D(X)$, the complex so constructed is independent of the choice of T and of $T \to B$, so that it deserves the designation of the relative cotangent complex $L_{X/Y}$ of X over Y. One also verifies that, on every affine open of X over an affine open of Y, it is given, up to canonical isomorphism, by the procedure of 4.3.

In the case where f is locally complete intersection, one sees moreover that the result is a perfect complex, which makes it possible again to define an element T_f of $K^\bullet(X)$ by formula (4.2). Here again, in general, it would not have been possible to define T_f as an element of $K^\bullet_{\text{naive}}(X)$, and nothing permits one to suppose that T_f is globally isomorphic in $D(X)$ to a bounded complex with locally free components of finite type. This is therefore an additional justification for the point of view advanced in 4.1 in favour of the "sophisticated" $K^\bullet(X)$, in preference to $K^\bullet_{\text{naive}}(X)$.

4.5

Subject to the question raised in 4.2, we have therefore again assembled all the structural elements needed to give a meaning to (1.2) for a proper locally complete intersection morphism of arbitrary schemes; the noetherian hypothesis implicitly made in the preceding sections can in fact be eliminated without any essential difficulty. Unfortunately, this does not mean that, even subject to this reservation, the formula in question is established, even in the case where Y is the spectrum of an algebraically closed field of characteristic $p > 0$ and X is, say, a proper smooth algebraic scheme of dimension 3. See the comments in Exposé XIV, no. 2.

5. Analytic variant

In the form presented in no. 4, the Riemann–Roch formula (1.2) also has a meaning for a proper locally complete intersection morphism of complex analytic spaces, or of rigid analytic spaces in the sense of Tate. But of course the proof given in [RRR] applies to this case only when one assumes in addition that the morphism f is projective; and, as in the algebraic case, it seems that an essentially new idea is needed to treat the general case. The formula we have in view here is a formula with values in an "analytic Chow ring" $\mathrm{Gr}^\bullet(X)$, or rather $\mathrm{Gr}^\bullet(X)_{\mathbb{Q}}$, constructed according to the principle explained in 4.2, the difficulty encountered there disappearing, moreover, because one is in characteristic zero, as is noted in Exposé XIV, no. 1.

When X and Y are nonsingular, it is possible to give another version of the Riemann–Roch formula by proceeding as follows. First let X be an arbitrary complex analytic space, and let X^{top} be the same space equipped with the sheaf of rings of continuous complex-valued functions. We therefore have a canonical morphism of ringed spaces

$$X^{\mathrm{top}} \longrightarrow X,$$

which, by the evident contravariant nature of the functor $K^\bullet(X)$ in the variable ringed space X, defines a homomorphism of rings

$$K^\bullet(X) \longrightarrow K^\bullet(X^{\mathrm{top}}). \tag{5.1}$$

For simplicity suppose that X^{top} is compact; then, as in the case of a scheme admitting an ample invertible module, one proves (Exposé II) that every perfect complex on X^{top} is globally isomorphic to a bounded complex, locally free in each degree, i.e. to a complex of complex vector bundles on X^{top}, and hence that $K^\bullet(X^{\mathrm{top}})$ is canonically isomorphic to the well-known group $K(X^{\mathrm{top}})$ of topologists [1], defined in terms of complex vector bundles on the compact space X^{top}. Thus one may interpret (5.1) as a homomorphism from the $K^\bullet(X)$ defined in terms of the analytic structure to the well-known ring $K(X^{\mathrm{top}})$ of topologists. If now

$$f : X \longrightarrow Y$$

is a morphism of compact nonsingular analytic spaces, one knows how to associate to it, thanks to Atiyah–Hirzebruch [1], a group homomorphism

$$f_*^{\mathrm{top}} : K^\bullet(X^{\mathrm{top}}) \longrightarrow K^\bullet(Y^{\mathrm{top}}). \tag{5.2}$$

Using likewise the homomorphism f_* of (3.1), defined by formula (3.2), which here implicitly uses Grauert's finiteness theorem [4] for a proper morphism of analytic spaces, one obtains a square of natural homomorphisms involving only groups of type $K^\bullet$, to the exclusion of rings of Chow-ring or cohomology type:

$$\begin{array}{ccc} K^\bullet(X) & \longrightarrow & K^\bullet(X^{\mathrm{top}}) \\ \downarrow f_* & & \downarrow f_*^{\mathrm{top}} \\ K^\bullet(Y) & \longrightarrow & K^\bullet(Y^{\mathrm{top}}). \end{array} \tag{5.3}$$

The Riemann–Roch type formula to which we are alluding consists in asserting the commutativity of this square. Note the difference in nature between this assertion, which does not neglect torsion phenomena and is situated in a group $K^\bullet(Y^{\mathrm{top}})$ of an essentially discrete nature, and the Riemann–Roch formula of the type considered in no. 4, which is situated in a group of "Chow" type no longer of a discrete nature, but which, on the other hand, must be tensored with $\mathbb{Q}$. Let us note that formula (5.3) is proved at any rate when X and Y are nonsingular projective varieties [7], as is the formula of the type considered in no. 4, proved in this case in

[RRR]. What is involved here is a plausible variant of the Atiyah–Singer index theorem, and of its generalizations due to Shih [7] and Atiyah, which obviously calls for a common generalization. Once the commutativity of (5.3) is proved, one would immediately deduce from it, using the "differentiable Riemann–Roch theorem" of Atiyah–Hirzebruch [1], a cohomological variant of the complex analytic Riemann–Roch formula, namely the commutativity of the diagram

$$\begin{array}{ccc} K^\bullet(X) & \xrightarrow{x\mapsto \mathrm{ch}(x)\,\mathrm{Todd}(T_X)} & H^{2\bullet}(X,\mathbb{Q}) \\ \downarrow f_* & & \downarrow f_* \\ K^\bullet(Y) & \xrightarrow{y\mapsto \mathrm{ch}(y)\,\mathrm{Todd}(T_Y)} & H^{2\bullet}(Y,\mathbb{Q}), \end{array} \tag{5.4}$$

where the horizontal arrows are deduced from cohomological Chern classes, themselves deduced from the homomorphism (5.1) and from the ordinary Chern-class homomorphism

$$K^\bullet(X^{\mathrm{top}}) \longrightarrow H^{2\bullet}(X,\mathbb{Z}),$$

the first vertical arrow is the same as in (5.3), and the second is the Gysin homomorphism in rational cohomology.

6. The covariant invariant $K_\bullet(X)$

In all that precedes, scarcely anything has been said except about the contravariant invariant $K^\bullet(X)$, to the exclusion of the covariant invariant $K_\bullet(X)$ whose existence was indicated in 3.1. If one regards $K^\bullet(X)$ as giving an analogue of the integral cohomology ring of a topological space, one should regard $K_\bullet(X)$ as giving an analogue of integral homology. The module structure of $K_\bullet(X)$ over $K^\bullet(X)$ then corresponds to the cap-product operation. The fact that, when X is regular, the natural homomorphism $K^\bullet(X) \to K_\bullet(X)$ is an isomorphism should be regarded as the analogue of the Poincaré duality theorem for oriented topological varieties, asserting that cap product with the fundamental homology class defines an isomorphism from cohomology to homology. These analogies moreover suggest the usefulness of also defining, for a finite polyhedron X, say, a covariant invariant $K_\bullet(X)$ whose relations to integral homology – spectral sequence, Chern homomorphism, and so on – would be analogous to those existing between $K^\bullet(X)$ and integral cohomology. Nor does it seem excluded that there might exist, in terms of these groups $K_\bullet(X)$, variants of the differentiable Riemann–Roch theorem valid for spaces more general than compact differentiable manifolds.

Returning to the case where X is an arbitrary noetherian scheme, one should endow $K_\bullet(X)$ with an increasing filtration, $\mathrm{Fil}_i\, K_\bullet(X)$ being generated by classes $\mathrm{cl}_\bullet(F)$, with F a coherent sheaf on X such that $\dim \mathrm{Supp}\, F \leq i$. One will prove (Exposé X) the compatibility of this filtration with the module structure and with the filtration of $K^\bullet(X)$, i.e. the formula

$$\mathrm{Fil}^i\, K^\bullet(X) \cdot \mathrm{Fil}_j\, K_\bullet(X) \subset \mathrm{Fil}_{j-i}\, K_\bullet(X), \tag{6.1}$$

which allows the graded group associated with the filtered module $K_\bullet(X)$, denoted $\mathrm{Gr}_\bullet(X)$, to be endowed with a module structure over $\mathrm{Gr}^\bullet(X)$. Its elements may in fact be interpreted as classes of algebraic cycles on X, for an equivalence relation less fine than rational equivalence when X is of finite type over a base field k. If

$$f : X \longrightarrow Y$$

is a proper morphism of noetherian schemes, then

$$f_* : K_\bullet(X) \longrightarrow K_\bullet(Y) \tag{6.2}$$

is compatible with the filtrations and defines a homomorphism of graded groups

$$f_* : \mathrm{Gr}_\bullet(X) \longrightarrow \mathrm{Gr}_\bullet(Y), \tag{6.3}$$

giving rise to a "projection formula", i.e. a formula which says that it is $\mathrm{Gr}^\bullet(Y)$-linear; this formula is obtained by passage to associated gradeds from the analogous projection formula for the homomorphism (6.2), which is $K^\bullet(Y)$-linear.

From the point of view proposed in the seminar, a manageable theory of intersections on noetherian schemes X, not necessarily regular, should consist in the combined study of the contravariant invariants $K^\bullet(X), \mathrm{Gr}^\bullet(X)$ and the covariant invariants $K_\bullet(X), \mathrm{Gr}_\bullet(X)$. These play roles of essentially different nature, and their properties complement each other. Thus the covariant groups $K_\bullet(X), \mathrm{Gr}_\bullet(X)$ are easier to compute for certain nonproper fibrations, thanks to the "homotopy exact sequence" which one can establish for them ([RRR] and Exposé IX). For example, one proves (Exposé IX) canonical isomorphisms such as

$$K_\bullet(X[t]) \simeq K_\bullet(X), \qquad \mathrm{Gr}_\bullet(X[t]) \simeq \mathrm{Gr}_\bullet(X),$$

which fail in general for $K^\bullet$ when X is a nonregular scheme. On the other hand, $K^\bullet(X)$ and $\mathrm{Gr}^\bullet(X)$ lend themselves well to computations, thanks to their ring structures.

When one considers schemes X proper over a field, the projection

$$\pi_X : X \longrightarrow (\text{point})$$

defines a homomorphism, the "Euler–Poincaré characteristic",

$$\chi_X = \pi_{X*} : K_\bullet(X) \longrightarrow K_\bullet(\text{point}) = \mathbb{Z}, \tag{6.4}$$

which induces on the subgroup $\mathrm{Gr}_0(X) = \mathrm{Fil}_0 K_\bullet(X)$ the homomorphism "degree of zero-cycles"

$$\deg_X : \mathrm{Gr}_0(X) \longrightarrow \mathbb{Z}. \tag{6.5}$$

The multiplication homomorphism

$$\mathrm{Gr}^i(X) \times \mathrm{Gr}_i(X) \longrightarrow \mathrm{Gr}_0(X),$$

composed with the degree homomorphism (6.5), then furnishes a pairing

$$\mathrm{Gr}^i(X) \times \mathrm{Gr}_i(X) \longrightarrow \mathbb{Z}, \tag{6.6}$$

which explains that, in certain respects, $\mathrm{Gr}^\bullet(X)$ and $\mathrm{Gr}_\bullet(X)$ play dual roles, just as cohomology and homology do. Thus, if $f : X \to Y$ is a morphism of proper algebraic schemes, the two homomorphisms

$$f^* : \mathrm{Gr}^\bullet(Y) \longrightarrow \mathrm{Gr}^\bullet(X), \qquad f_* : \mathrm{Gr}_\bullet(X) \longrightarrow \mathrm{Gr}_\bullet(Y)$$

are formally transposes of one another, in the sense of the pairings (6.6).

The homomorphisms (6.4) and (6.5), and the pairing (6.6) deduced from them, may be regarded as the source of numerical relations in intersection theory on proper algebraic schemes over a given field k. This point of view will be developed in some detail in Exposé X, which is essentially independent of Exposés VI, VII, VIII, centred on the proof of the Riemann–Roch theorem, and of Exposé IX. Some notions concerning the behaviour of $K^\bullet(X)$ and $\mathrm{Gr}^\bullet(X)$ under specialization will also be given there.

7. Picard groups and the determinant functor

As in every intersection theory, it is important to specify the place occupied in the theory by the Picard group, or group of classes of divisors in the classical terminology. Subject to a slight restriction, automatically satisfied when X is for instance quasi-compact, one establishes in Exposé X a canonical isomorphism

$$c_1 : \mathrm{Pic}(X) \xrightarrow{\sim} \mathrm{Gr}^1(X), \tag{7.1}$$

which shows the exact role of the Picard group in the theory we are proposing. This role justifies a more detailed study of the Picard group in Exposés XII and XIII, which are logically independent of the text of the seminar. Kleiman, in Exposé XIII, studies numerical equivalence and certain finiteness theorems for the Picard group, announced without proof in [6], using purely numerical techniques, not relying on the theory of the Picard functor and its representability, due to himself and Mumford, and markedly simpler than Grothendieck's initial proofs. The only result refractory to Kleiman's methods, and which he is obliged to use, is [6, C-07 (i)]; its proof and certain refinements, including certain representability theorems for the Picard functor, occupy Exposé XII. The latter is moreover of a spirit and technique entirely foreign to the rest of the seminar, and is connected with [5]; this exposé is logically independent of all the others.

Finally, in Exposé XI, of a nature appreciably more general than XII and XIII and closer to the general spirit of the seminar, one studies, on an arbitrary locally ringed topos, a remarkable functor called the "determinant functor":

$$\overset{\bullet}{\det} : \mathrm{Parf}_{\mathrm{is}}(X) \longrightarrow \mathrm{Inv}(X) \tag{7.2}$$

from the category of perfect complexes on X, whose morphisms are only the isomorphisms in the sense of the derived category $D(X)$, to the category of invertible modules on X. This functor is described, up to very little, by the requirement that it be of "local nature" and that it be given, for a bounded complex L with locally free components, by the formula

$$\overset{\bullet}{\det}(L) = \bigotimes_i \det(L_i)^{(-1)^i}, \tag{7.3}$$

where $\det(L_i)$ denotes the exterior power of maximal degree of the locally free module L_i. Although this exposé is also logically independent of the rest of the seminar, except for Exposé I, it nevertheless constitutes an important element of the general "yoga" proposed in the seminar and developed essentially in Exposés I to XI.

Chapter I. λ-rings (formal preliminaries)

1. Definitions

A λ-*ring*[2] means a commutative ring K with unit, provided with a family of maps

$$\lambda^i : K \longrightarrow K \qquad (i \text{ an integer } \geq 0) \tag{1.1}$$

satisfying the following conditions:

$$\lambda_x^0 = 1, \qquad \lambda_x^1 = x, \qquad \lambda^n(x+y) = \sum_{i=0}^{n} \lambda_x^i \lambda_y^{n-i}. \tag{1.2}$$

For every $x \in K$ put

$$\lambda_t(x) = \sum_{n \geq 0} \lambda^n(x) t^n \in K[[t]]. \tag{1.3}$$

[1]This is the literal reproduction of the report cited in the Introduction to the present seminar. The footnotes indicated by the signs (*), (**) were added in October 1967.

[2]In this seminar we rather say *pre-*λ*-ring* (V 2.1), reserving the name λ-ring for those satisfying the supplementary condition of page 3 (cf. V 2.4).

The preceding relations then say that $x \mapsto \lambda_t(x)$ is a homomorphism from the additive group K to the multiplicative group $1 + K[[t]]^+$ of formal series over K with augmentation 1, lifting the canonical homomorphism

$$1 + \sum_{i>0} x_i t^i \longmapsto x_1.$$

Thus on the ring $\mathbb{Z}$ there exists a unique λ-structure compatible with its ring structure and such that

$$\lambda_t(1) = 1 + t. \tag{1.4}$$

One then has

$$\lambda_t(n) = (1 + t)^n, \tag{1.5}$$

whence

$$\lambda^i(n) = \binom{n}{i}.$$

The notion of a λ-homomorphism of λ-rings is clear; an *augmented* λ*-ring* is a λ-ring provided with a λ-homomorphism to $\mathbb{Z}$.

To define the notion of a *special* λ-ring, the following considerations are useful. Let k be a commutative ring with unit and let

$$K = 1 + k[[t]]^+$$

be the group of formal series with coefficients in k and augmentation 1. We shall introduce on it a λ-ring law whose additive structure is the multiplication of formal series. The multiplication of this ring will be denoted $f \circ g$. It is entirely determined by the condition that the coefficients $c_n = c_n(f \circ g)$ of $f \circ g$ are given by universal polynomials with integral coefficients in the coefficients $a_i = c_i(f)$ and $b_i = c_i(g)$ of f and g, respectively:

$$c_n = P_n(a_1, \ldots, a_n; b_1, \ldots, b_n), \tag{1.6}$$

that it be distributive with respect to the "addition" fg, and be given for linear factors by

$$(1 + at) \circ (1 + bt) = 1 + abt. \tag{1.7}$$

The P_n are computed by calculations with symmetric functions; P_n is isobaric of weight n in the a_i and isobaric of weight n in the b_i (where a_i and b_i have weight i), and moreover is symmetric in $a = (a_i)$ and $b = (b_i)$.

Similarly, the $\lambda^i(f)$ are determined without ambiguity by the condition that the coefficients

$$c_n(\lambda^i(f)) = c_n(\lambda^i(f))$$

of $\lambda^i(f)$ be calculated by universal polynomials with integral coefficients in the coefficients $c_n(f) = a_n$ of f:

$$c_n = P_{i,n}(a_1, \ldots, a_{in}), \tag{1.8}$$

that the relations (1.2) be satisfied, and that, for $i > 1$, one have

$$\lambda^i(1 + at) = 1 \tag{1.9}$$

(1 is the zero element of the ring $K = 1 + k[[t]]^+$). The $P_{i,n}$ are again computed by calculations with symmetric functions, and one observes that $P_{i,n}$ is an isobaric polynomial of weight in in the a_i. Provided with the preceding operations, K becomes a λ-ring; its zero element is 1 and its unit element is $1 + t$. Also note the relation

$$(1 + at) \circ f = f(at). \tag{1.7 bis}$$

Let now K be an arbitrary λ-ring. We say that K is *special* if the additive homomorphism λ_t from K to $1 + K[[t]]^+$ is a λ-homomorphism. Thus this means that one has the formulas

$$\lambda_t(1) = 1 + t, \quad \lambda_t(xy) = \lambda_t(x) \circ \lambda_t(y), \quad \lambda_t(\lambda^i(x)) = \lambda^i(\lambda_t(x)), \tag{1.10}$$

or, more explicitly,

$$\begin{cases} \lambda^i(1) = 0 & \text{if } i > 1, \\ \lambda^n(xy) = P_n(\lambda^1 x, \dots, \lambda^n x; \lambda^1 y, \dots, \lambda^n y), & \\ \lambda^n(\lambda^i(x)) = P_{i,n}(\lambda^1 x, \dots, \lambda^{in} x), & \end{cases} \tag{1.11}$$

where the P_n and $P_{i,n}$ are the universal polynomials considered above. In particular the formulas (1.5) follow. One may show that the λ-ring $1 + k[[t]]^+$ constructed from a commutative ring k is special, but we shall not need this fact.

2. Examples

1) Let G be a group and k a commutative ring. Consider the group $K(G)$, the quotient of the free group generated by the classes of representations of G in finite-type k-modules by the subgroup generated by elements of the form

$$(\rho \oplus \rho') - (\rho) - (\rho')$$

(where $\oplus$ denotes the direct sum). Tensor product and exterior powers define on $K(G)$ a λ-ring structure. One may also pass to the quotient by elements of the form

$$(\rho) - (\rho') - (\rho''),$$

where ρ is a representation which is an extension of ρ' by ρ'', trivial as an extension of k-modules. One obtains the group $K_r(G)$ of reduced classes of representations of G, and one checks that the λ-ring law passes to the quotient.

When k is an algebraically closed field of characteristic 0,[3] one can show that $K(G)$, and a fortiori $K_r(G)$, is a special λ-ring. This is no longer true if the characteristic is not 0; however, if k is algebraically closed, $K_r(G)$ is still a special λ-ring. To prove this one is reduced to the case where G is a product $\mathrm{Gl}(m,k) \times \mathrm{Gl}(n,k)$ and where only rational representations of G are considered; our assertion follows from the explicit determination of $K_r(G)$ to be made below (Example 3). Finally, when k has characteristic 0, complete reducibility of rational representations of G shows that $K(G) = K_r(G)$.

Variants of the preceding example: G is an algebraic group defined over k and one considers only rational representations of G defined over k; one may consider the case of a topological group, or of a Lie group, and continuous representations, etc.[4]

2) Let X be an algebraic variety, irreducible or not, defined over the field k. We may consider the quotient group of the free group generated by the classes of vector bundles on X (defined over k) by the subgroup generated by the elements of the form

$$(E \oplus E') - (E) - (E'),$$

[3] It is unnecessary for k to be algebraically closed; cf. VI 3.3 for a still more general result, encompassing all those that will be used in the present report.

[4] One could build other examples of λ-rings; for example, the set of equivalence classes of quadratic forms, the set of representation classes of a Lie algebra, etc. We promise that we shall not need all these examples in order to treat the Riemann–Roch theorem.

on which the λ-ring operations are defined by tensor product and exterior powers. If X is complete, this is a free group generated by the indecomposable vector bundles on X (thanks to Krull–Remak–Schmidt); knowledge of this ring and of its basis is equivalent to the complete classification of vector bundles on X and to knowledge of the elementary tensor operations on these bundles. If k is algebraically closed of characteristic 0, all other tensor operations on classes of vector bundles are then known by means of what follows in 3). One may make a more drastic passage to the quotient by the group generated by the elements

$$(E) - (E') - (E''),$$

where E is a vector bundle extension of E' by E''. One then obtains a λ-ring, denoted $K(\xi(X))$, where $\xi(X)$ denotes the additive category of vector bundles on X defined over k. Using the results of Example 1), one shows that, if k is algebraically closed,[5] the λ-ring $K(\xi(X))$ is special, and that the same is true of the first λ-ring defined here if the characteristic of k is 0, but not in the general case.

3) Determination of $K(G)$ and of $K_r(G)$ in some important cases. Suppose the field k is algebraically closed and that the group G is affine algebraic, connected, and "globally reductive" (the radical of G is isomorphic to $(k^*)^s$), and consider only rational linear representations. In characteristic 0, complete reducibility of rational linear representations of G shows that $K(G) = K_r(G)$ is the free group generated by the classes of irreducible rational representations. If T is a maximal torus of G, then

$$K(T) = K_r(T) = \mathbb{Z}(\widehat{T}),$$

the algebra of the group $\widehat{T}$ of rational characters of T; one has $\widehat{T} \simeq \mathbb{Z}^r$ if r is the rank of G (this is independent of the characteristic). The Weyl group W operates on T, hence on $K(T)$, in a way which depends only on the operations of W on the free group $\widehat{T}$. There is an evident homomorphism of λ-rings, deduced from the injection of T into G:

$$K_r(G) \longrightarrow K_r(T)^W = K(T)^W, \tag{1.13}$$

where $K(T)^W$ denotes the set of fixed points of W in $K(T)$. The theory of linear representations of G[6] then proves the following theorem.

Theorem 1.1. The homomorphism (1.13) is an isomorphism.

Thus one sees that $K_r(G)$, once the "type" of G is known (characterized by W operating on a group $\mathbb{Z}^r$), does not depend on the characteristic, and that it is a special λ-ring. There is a canonical basis of $K_r(G)$ corresponding to the orbits of W in $\widehat{T}$; another basis is obtained as follows. Let $(\rho_i)_{1\leq i\leq r'}$ be the classes of representations of G corresponding to the fundamental representations of $G/\operatorname{rad} G$, and let $(\sigma_j)_{1\leq j\leq r''}$ be a basis of the group of rational homomorphisms from G to k^*. Thus $r' + r'' = r$ (the rank of G).

Corollary. The ring $K_r(G)$ is identified with the subring

$$\mathbb{Z}[\rho_1, \ldots, \rho_{r'}; \sigma_1, \ldots, \sigma_{r''}, \sigma_1^{-1}, \ldots, \sigma_{r''}^{-1}]$$

of the field of rational functions in the ρ_i and the σ_j with coefficients in $\mathbb{Q}$.[7]

In particular, $K_r(G)$ has no zero divisors. If $G = \prod_i \mathrm{Gl}(n_i, k)$, the ring $K_r(G)$ is made explicit as follows. Let ρ_i be the representation of G deduced from the identical representation of $\mathrm{Gl}(n_i, k)$. If one then considers the field of rational functions over $\mathbb{Q}$ in the indeterminates

[5] Unnecessary condition; cf. the preceding footnote.

[6] Cf. Chevalley Seminar 1956/58, *Groupes de Lie algébriques* (École Normale Supérieure).

[7] The derived group G' of G must be supposed simply connected for this statement to be correct.

$\lambda^j(\rho_i)$, $1 \leq j \leq n_i$, then $K_r(G)$ is identified with the subring generated by these indeterminates and the inverses of the $\lambda^{n_i}(\rho_i)$. This justifies our assertion that, at least in characteristic 0, the operations λ^i make it possible to reconstruct all tensor operations on vector bundles; this remains true over an algebraically closed field of arbitrary characteristic, provided one takes reduced classes.

Remarks. a) In Example 1), the ring $K(G)$ is augmented, the augmentation being defined by the degree of representations; by passage to the quotient, this augmentation defines an augmentation on $K_r(G)$. Likewise, the λ-rings considered in Example 2) are augmented when X is k-irreducible; in $K(\xi(X))$, the augmentation is defined by the rank of a vector bundle, that is, the dimension of its fibres.

b) When the field k is not algebraically closed, it is plausible that $K(G)$ is a special λ-ring in characteristic 0, and likewise for $K_r(G)$ in all characteristics.

c) In non-zero characteristic, Theorem 1.1 was graciously supplied by Chevalley.

3. The λ-ring defined by a graded ring

Let A be a graded commutative ring with unit. To simplify, assume that the degrees of A are positive and that $A^0 = \mathbb{Z}$. Denote by $\widehat{A}$ the product of the A^i (this is a commutative ring with unit), and by $\widehat{A}^+$ the kernel of the evident augmentation $\widehat{A} \to A^0 = \mathbb{Z}$. Then $1 + \widehat{A}^+$ is a subgroup of the multiplicative group of invertible elements of $\widehat{A}$. Consider the abelian group

$$\widetilde{A} = \mathbb{Z} \times (1 + \widehat{A}^+), \tag{1.14}$$

whose elements will be denoted $[n, x]$, with $n \in \mathbb{Z}$ and

$$x = 1 + \sum_{i \geq 1} x^i \in 1 + \widehat{A}^+ \qquad (x^i \in A^i).$$

We write this group additively, thus:

$$[n, x] + [n', x'] = [n + n', xx']. \tag{1.15}$$

The zero element of this group is $[0, 1]$. We shall introduce on it an augmented λ-ring structure, compatible with its additive structure, the augmentation being $\varepsilon : [n, x] \mapsto n$. The product $[m, x][n, y]$ is completely characterized by the fact that it is written

$$[mn, x^n y^m (x * y)],$$

where $x * y$ is an element of $1 + \widehat{A}^+$ whose components are expressed as universal polynomials with integral coefficients in the x^i and the y^i:

$$(x * y)^i = Q_i(x^1, \ldots, x^i; y^1, \ldots, y^i) \qquad (i \geq 1), \tag{1.16}$$

the polynomial Q_i being isobaric of weight i. Moreover, $x * y$ must be distributive with respect to the "addition" xy and, for "linear" factors, must reduce to

$$[1, 1 + x^1][1, 1 + y^1] = [1, 1 + x^1 + y^1]. \tag{1.17}$$

The polynomials Q_i are evaluated by calculations with elementary symmetric functions. This is the calculation of the Chern classes of a tensor product of vector bundles by means of the Chern classes x^i and y^i of the factors and of their respective dimensions m and n. From (1.17) one deduces

$$(1 + x^1) * (1 + y^1) = \frac{1 + x^1 + y^1}{(1 + x^1)(1 + y^1)}, \tag{1.17 bis}$$

and an arbitrary product $x * y$ is computed term by term by decomposing formally

$$x = \prod_{i=1}^{n}(1+\alpha_i), \qquad y = \prod_{i=1}^{n}(1+\beta_i),$$

where the α_i and β_i have degree 1.

In this way $\widetilde{A}$ becomes a commutative augmented ring with unit $[1,1]$; it may be interpreted as the ring obtained by adjoining a unit to the ring $1+\widehat{A}^+$. Moreover, on $\widetilde{A}$ one defines a filtration by putting $\widetilde{A}^0 = \widetilde{A}$ and denoting by $\widetilde{A}^n$ the set of the $[0,x]$ with $x^i = 0$ for $1 \leq i < n$. This filtration is compatible with the product, for

$$\left(1+\sum_{i\geq m} x^i\right) * \left(1+\sum_{j\geq n} y^j\right) = 1 - \frac{(m+n-1)!}{(m-1)!(n-1)!}x^m y^n + \cdots, \tag{1.18}$$

the omitted terms having degree $> m+n$. This formula shows that the graded ring $G(\widetilde{A})$ associated with $\widetilde{A}$ is identified with A from the additive point of view, but not from the multiplicative point of view. One can only say that the map η' from A to $G(\widetilde{A})$ defined by

$$\eta'(x^i) = (-1)^{i-1}(i-1)!\,x^i \qquad (x^i \in A^i) \tag{1.19}$$

is a ring homomorphism.

On $\widetilde{A}$ introduce operations λ^i satisfying the axioms of λ-rings (Section 1, formulas (1.2)), well determined by the condition that the components of $\lambda^i[0,x]$ be deduced from the components x^i of x by universal polynomials with integral coefficients:

$$\lambda^i[0,x] = [0,\lambda^i x], \qquad (\lambda^i x)^{(n)} = Q_{i,n}(x^1,\ldots,x^n), \tag{1.20}$$

where $Q_{i,n}$ is isobaric of weight n, and such that

$$\lambda^i[1,1+x^1] = 0 \qquad \text{for } i > 1. \tag{1.21}$$

The polynomials $Q_{i,n}$ are evaluated by a calculation with elementary symmetric functions: it is the calculation of the Chern classes of the exterior powers of a vector bundle by means of the Chern classes and the rank of that bundle. One then observes that $\widetilde{A}$ is a special augmented λ-ring and that the $\widetilde{A}^i$ are stable under the operations λ^j.

The augmented λ-ring $\widetilde{A}$ may be considered as a functor in A. Consequently, the principal automorphism

$$x = \sum_{i\geq 0} x^i \longmapsto \check{x} = \sum_{i\geq 0}(-1)^i x^i$$

of A defines an automorphism of $\widetilde{A}$, denoted by the same symbol $\check{}$.

Proposition 1.2. Let $x \in \widetilde{A}$ be of the form

$$x = [n, 1 + x^1 + \cdots + x^n]$$

(so $x^i = 0$ for $i > n$). Then $\lambda^i(x) = 0$ for $i > n$, one has $\lambda^n(x) = [1, 1+x^1]$, and finally

$$\sum_{i=0}^{n}(-1)^i\lambda^i(x) = [0, 1-(n-1)!x^n + \cdots]. \tag{1.22}$$

From this proposition, and from the fact that the $\widetilde{A}^i$ are stable under the operations λ^j, it follows that formula (1.22) is valid whenever $\varepsilon(x) = n$, whether or not $x^i = 0$ for $i > n$.

Formula (1.22) admits the following generalizations. Let K be any λ-ring, and let n be arbitrary. For $x \in K$, put

$$\gamma^n(x) = (-1)^n \sum_{i=0}^{n} (-1)^i \lambda^i(x+n) = \lambda^n(x+n-1) \tag{1.23}$$

(the identity of the last two members follows from an immediate induction). In particular $\gamma^0(x) = 1$ and $\gamma^1(x) = x$. Next put

$$\gamma_t(x) = \sum_{n \geq 0} \gamma^n(x) t^n \in K[[t]]. \tag{1.24}$$

One deduces the formula

$$\gamma_t(x) = \lambda_{t/(1-t)}(x), \tag{1.25}$$

which is equivalent to

$$\lambda_s(x) = \gamma_{s/(1+s)}(x). \tag{1.25 bis}$$

This proves that the λ^i are expressed in terms of the γ^i, and that

$$\gamma_t(x+y) = \gamma_t(x)\gamma_t(y).$$

Consequently the maps γ^i define a new λ-ring structure on K. Formula (1.22) then shows that, for $K = \widetilde{A}$ and every $x \in \widetilde{A}$, one has

$$\gamma^n(x - \varepsilon(x)) = [0, 1 + (-1)^{n-1}(n-1)! x^n + \cdots], \tag{1.22 bis}$$

and hence the component x^n is obtained, up to the factor $(-1)^{n-1}(n-1)!$, by reducing modulo $\widetilde{A}^{n+1}$ the element $\gamma^n(x - \varepsilon(x))$ of $\widetilde{A}^n$.

The Chern homomorphism. For every graded ring A satisfying the preceding conditions, we shall define a homomorphism of augmented rings

$$\mathrm{ch} : \widetilde{A} \longrightarrow \widehat{A} \otimes \mathbb{Q}. \tag{1.26}$$

This homomorphism is defined without ambiguity by the condition that it be an additive homomorphism, send 1 to 1, and be such that the components of $\mathrm{ch}(x)$ in degree > 0 are given by universal isobaric polynomials with rational coefficients in the components of x, and that

$$\mathrm{ch}([1, 1 + x^1]) = \exp x^1 = \sum_{n \geq 0} (x^1)^n / n!. \tag{1.27}$$

One immediately obtains the explicit expression of ch. Let η be the additive endomorphism of $\widehat{A} \otimes \mathbb{Q}$ defined, for x^i of degree i, by

$$\eta(x^i) = \frac{1}{(-1)^{i-1}(i-1)!} x^i. \tag{1.28}$$

Then

$$\mathrm{ch}\left([n, 1 + \sum_{i \geq 1} x^i]\right) = n + \eta\left(\log\left(1 + \sum_{i \geq 1} x^i\right)\right). \tag{1.29}$$

Since this formula can be inverted, at least if A has only finitely many homogeneous components, one sees that in this case one has an isomorphism ch from the ring $\widetilde{A} \otimes \mathbb{Q}$ onto the ring $\widehat{A} \otimes \mathbb{Q}$, which completely elucidates the structure of $\widetilde{A} \otimes \mathbb{Q}$.

Recall that, according to Hirzebruch [1], a formal series $f \in \mathbb{Q}[[t]]$ defines by universal polynomial formulas an additive homomorphism

$$1 + \widehat{A}^+ \longrightarrow 1 + (\widehat{A} \otimes \mathbb{Q})^+,$$

denoted $\mathfrak{C}_f$. When $f(t) = t/(1-\exp(-t))$, we write simply $\mathfrak{C}_f = \mathfrak{C}$ (the initial of Todd). We extend the definition of $\mathfrak{C}(x)$ to $x \in \widetilde{A}$. This said, we have the following result.

Proposition 1.3. Let $N \in \widetilde{A}$ be of the form

$$N = [q, 1 + N^1 + \cdots + N^q]$$

(so $N^i = 0$ for $i > q$). If one puts

$$\lambda_{-1}(N) = \sum_{i \geq 0} (-1)^i \lambda^i(N) = \sum_{i=0}^{n} (-1)^i \lambda^i(N),$$

then

$$\mathrm{ch}(\lambda_{-1}(N)) = (-1)^q N^q \mathfrak{C}(\check{N})^{-1}, \tag{1.30}$$

which is equivalent to

$$\mathrm{ch}(\lambda_{-1}(\check{N})) = N^q \mathfrak{C}(N)^{-1}. \tag{1.30 bis}$$

4. The operations $\lambda^p(N, x)$

Let A be the ring of formal series, with coefficients in $\mathbb{Z}$, in two infinite sequences of indeterminates denoted $\lambda^i N$ and $\lambda^i x$ $(i \geq 1)$. Put $\lambda^1 N = N$ and $\lambda^1 x = x$, and introduce on A the unique special λ-ring structure for which

$$\lambda^i(N) = \lambda^i N, \qquad \lambda^i(x) = \lambda^i x,$$

and for which the operations λ^i are continuous. If one restricted oneself to polynomials in the indeterminates $\lambda^i N$ and $\lambda^i x$, one would have the λ-ring freely generated by N and x; our ring A is its completion. One may then form

$$\lambda_{-1}(N) = \sum_{i \geq 0} (-1)^i \lambda^i N, \tag{1.31}$$

which is a formal series with constant term 1, hence invertible. Thus an element $\lambda^p(N, x)$ of A can be defined without ambiguity by putting

$$\lambda^p(N, x)\lambda_{-1}(N) = \lambda^p(x\lambda_{-1}(N)). \tag{1.32}$$

Theorem 1.4. Let J_q be the closed ideal of A generated by the $\lambda^i N$ with $i > q$. Identify A/J_q with the ring of formal series in the $\lambda^i x$ and the $\lambda^j N$ $(1 \leq j \leq q)$. Then $\lambda^p(N, x)$ reduced modulo J_q is a polynomial, isobaric of weight p with respect to the variables $\lambda^i x$.

Let N and F be two vector spaces of finite dimensions q, q' over an algebraically closed field k of characteristic 0. Let $N^{(p)}$ be the kernel of the map

$$(a_1, \ldots, a_p) \longmapsto a_1 + \cdots + a_p$$

from N^p to N. We make the symmetric group $\mathfrak{S}_p$ operate on N^p, hence on $N^{(p)}$, hence on $\Lambda(N^{(p)})$, and then on

$$\Lambda(N^{(p)}) \otimes \bigotimes^p F.$$

Consider this vector space as a graded module over $\mathfrak{S}_p \times \mathrm{Gl}(N) \times \mathrm{Gl}(F)$, and take its "alternating part", which is a graded module over $\mathrm{Gl}(N) \times \mathrm{Gl}(F) = G$. Then

$$\lambda^p(N, F) = E_G \left(\left(\Lambda(N^{(p)}) \otimes \bigotimes^p F \right)^{\mathrm{alt}} \right). \tag{1.33}$$

N.B. If M is a complex of G-modules, $E_G(M)$ denotes the alternating sum in $K(G)$ of the classes of the components of M, that is, the Euler–Poincaré characteristic of M. In formula (1.33), the first member $\lambda^p(N,F)$ denotes the element of the ring $K(G)$ obtained by substituting, for the variables λ^i_N and λ^i_F, the classes in $K(G)$ of the G-modules $\lambda^i(N)$ and $\lambda^i(F)$, respectively.

Proof. Expanding the second member of (1.32) by the second formula (1.11), one sees that the first assertion is proved if one proves the analogous assertion obtained by setting $x = 1$, i.e. if one proves that in the λ-ring $\mathbb{Z}[\lambda^1 N, \ldots, \lambda^q N]$, where $\lambda^i N = 0$ for $i > q$, the element $\lambda^p(\lambda_{-1}(N))$ is divisible by $\lambda_{-1}(N)$. A priori, the quotient

$$\lambda^p(N,1) = \lambda^p(\lambda_{-1}(N))/\lambda_{-1}(N)$$

is a formal series contained in the quotient field K of the ring of formal series in the $\lambda^i N$ for $1 \leq i \leq q$. On the other hand, also denote by N a vector space of dimension q over an algebraically closed field k of characteristic 0, and consider the element

$$\mathscr{L}^p(N) = E_G((\Lambda(N^{(p)}))^{\mathrm{alt}}) \in K(G),$$

where now $G = \mathrm{Gl}(N)$. We know (Section 2, Theorem 1.3) that $K(G)$ is identified with the subring of K generated by the λ^i_N for $1 \leq i \leq q$ and by the inverse of λ^q_N. Moreover, in this ring one verifies easily that

$$\mathscr{L}^p(N)\lambda_{-1}(N) = \lambda^p(\lambda_{-1}(N)).$$

Since we are in a large field K and $\lambda_{-1}(N) \neq 0$, it follows that $\mathscr{L}^p(N) = \lambda^p(N,1)$. Both members lie in the intersection of $K(G)$ with the ring of formal series in the λ^i_N, hence are polynomials in the λ^i_N.

To prove (1.33) in the general case, one verifies that the second member satisfies in $K(G)$ the formula analogous to (1.32), that is, that its product by $\lambda_{-1}(N)$ is $\lambda^p(F\lambda_{-1}(N))$. Likewise, the product of $\lambda^p(N,F) \in K(G)$ by $\lambda_{-1}(N)$ is $\lambda^p(F\lambda_{-1}(N))$, as follows from the fact that $K(G)$ is special. Since $K(G)$ is integral (cf. Section 2), and $\lambda_{-1}(N) \neq 0$ (same reference), formula (1.33) is proved. QED.

Remarks. a) When the dimension q' of F is at least p, formula (1.33) characterizes the polynomial $\lambda^p(N,x)$ in the λ^i_N $(1 \leq i \leq q)$ and the λ^j_x $(1 \leq j \leq p)$.

b) It is plausible that (1.33) remains valid if the field k is not algebraically closed.[8] One would have to resolve this question if one wanted to prove the Riemann–Roch theorem over a non-algebraically-closed field of characteristic 0 by the method to be explained. The passage from an $\mathfrak{S}_p$-module to its alternating part has reasonable meaning only when the base field has characteristic 0.

Let now K be any special λ-ring and let N be an element of K such that $\lambda^i N = 0$ for all sufficiently large i. Then for every $x \in K$ and every integer $p \geq 1$ one can consider the elements $\lambda^p(N,x)$, which are expressed by universal polynomials with integral coefficients in the λ^i_N and the λ^j_x. One has $\lambda^1(N,x) = x$ and formula (1.32) in K. To express the properties of the operations $x \mapsto \lambda^p(N,x)$, it is convenient to introduce a new λ-ring, denoted K_N. As a commutative ring, K_N is obtained by adjoining a unit to the ring whose underlying additive group is K and whose multiplication is given by

$$x_N y = xy\mu \qquad (\mu = \lambda_{-1}(N)). \tag{1.34}$$

The map λ_t from K_N to $K_N[[t]]$ is defined by

$$\lambda_t(n,x) = (1+t)^n \sum_{p \geq 0} \lambda^p(N,x)t^p, \tag{1.35}$$

[8] This is in fact proved by the same method.

where $\lambda^0(N,x) = (1,0)$ (the unit element of K_N). I say that, with these operations, K_N is a special λ-ring. Thus one has to verify the formulas

$$\lambda_t(X+Y) = \lambda_t(X)\lambda_t(Y), \qquad \lambda_t(XY) = \lambda_t(X)\lambda_t(Y), \qquad \lambda_t(\lambda^i(X)) = \lambda^i(\lambda_t(X))$$

for $X, Y \in K_N$. One may restrict oneself to verifying these formulas when X and Y lie in K, and one checks that it suffices to verify them when K is the free special λ-ring generated by X, Y and N subject to the relations $\lambda^i N = 0$ for $i > q$. But the group homomorphism

$$K_N \longrightarrow K, \tag{1.36}$$

which sends unit to unit and on K reduces to the homomorphism $x \mapsto x\mu$, is a homomorphism compatible with the ring structures and the maps λ^i, as one verifies immediately. In the present case, its restriction to K is injective. Since K is a special λ-ring, it follows easily that the above relations are indeed verified for $X, Y \in K$, completing the proof of our assertion.

According to formula (1.23), it is natural, for $x \in K$ and $n \geq 1$, to put

$$\gamma^n(N,x) = \sum_{i=0}^{n-1} \binom{n-1}{i} \lambda^i(N,x), \tag{1.37}$$

in other words, $\gamma^n(N,x) = \gamma^n(x_N)$, where x_N denotes x considered as an element of the λ-ring K_N.

Proposition 1.5. Let A be a graded commutative ring with unit, let N be an element of $\widetilde{A}$ of the form

$$N = [q, 1 + N^1 + \cdots + N^q],$$

and let x be an arbitrary element of $\widetilde{A}$:

$$x = [\nu, 1 + \sum_{i \geq 1} x^i].$$

Then, for every integer $j \geq 0$, one has $\gamma^{q+j}(N,x) \in \widetilde{A}^j$, and the component of degree j of $\gamma^{q+j}(N,x)$ is of the form

$$\left(\gamma^{q+j}(N,x)\right)^{(j)} = (-1)^{j-1}(j-1)!\, G_{q,j}(\nu, x^1, \ldots, x^j; N^1, \ldots, N^j), \tag{1.38}$$

where $G_{q,j}$ is a universal polynomial with integral coefficients characterized by the condition

$$G_{q,j}(\nu, x^1, \ldots, N^j)\,(N^q) = (-1)^q (x * \lambda_{-1}(N))^{(q+j)}. \tag{1.39}$$

Proof. We may suppose that A is the ring of polynomials with integral coefficients in indeterminates x^i and N^j $(1 \leq j \leq q)$. Since, combining (1.32) and (1.37), one has

$$\gamma^n(N,x)\lambda_{-1}(N) = \gamma^n(x\lambda_{-1}(N)), \tag{1.40}$$

and, for $n = q + j$, the second member has filtration $\geq q + j$ (use formula (1.22 bis), taking account of the fact that $x\lambda_{-1}(N)$ has zero augmentation), while $\lambda_{-1}(N)$ has filtration q (formula (1.22)), it follows that $\gamma^n(N,x)$ has filtration j, since by (1.18) the associated graded of A is integral here. Using the preceding formulas, one immediately obtains the indicated form for $(\gamma^{q+j}(N,x))^{(j)}$. QED.

Chapter II. Classes of coherent algebraic sheaves and Chern classes

1. The theory of Chow

Throughout this chapter, a base field k is fixed; for simplicity it will be assumed algebraically closed. A large part of what follows, perhaps all of it, is nevertheless valid without this restriction. The algebraic spaces and the regular maps considered will be defined over k.

An algebraic space is called *quasi-projective* if it is isomorphic to a locally closed subset of a projective space.

Let X be a nonsingular connected quasi-projective variety of dimension n. Denote by $A(X)$, and call the *Chow ring* of X, the graded ring of classes of cycles on X modulo rational equivalence. Thus $A^i(X)$ is formed from the classes of cycles of dimension $n-i$. The fact that $A(X)$ is indeed a graded ring follows from the following theorem of Chow.

Theorem 2.1.[9] Every cycle on X is rationally equivalent to a nonsingular cycle. Given elements of $A^i(X)$ and $A^j(X)$, one can find nonsingular representatives of these elements, say Y^{n-i} and Z^{n-j}, which meet everywhere transversely.

A cycle is called nonsingular if its components are nonsingular subvarieties. Two cycles are said to meet everywhere transversely if every component of one cuts every component of the other transversely, i.e. if the two secant varieties are nonsingular at their intersection points and their tangent varieties there are in general position.

Let f be a morphism, i.e. a regular map, from X to Y (where X and Y are quasi-projective and nonsingular). Then f defines, using the preceding theorem, a homomorphism of graded rings

$$f^* : A(Y) \longrightarrow A(X), \tag{2.1}$$

namely inverse image of cycle classes. Thus $A(X)$ becomes a contravariant functor in X.

Let f be a proper morphism from X^n to Y^m (i.e. in Weil's terminology, the graph of f is complete over Y, cf. [3]). Then f also defines an additive homomorphism

$$f_* : A(X^n) \longrightarrow A(Y^m), \tag{2.2}$$

preserving the dimension of cycles, hence increasing the degree by $m-n$.

Thus, relative to proper morphisms, and ignoring multiplicative structures and gradings, $A(X)$ is a covariant functor in X. Let us record the classical formula

$$f_*(x \cdot f^*(y)) = f_*(x) \cdot y. \tag{2.3}$$

We shall also use Chow's theory of Chern classes. It consists in attaching to every vector bundle E on X (still assumed quasi-projective and nonsingular) Chern classes

$$c^i(E) \in A^i(X) \qquad (i \geq 1),$$

in such a way as to satisfy the following conditions. Put $c^0(E) = 1$ and

$$\widetilde{C}(E) = \left[\operatorname{rank} E, \sum_{i \geq 0} c^i(E)\right] \in \widetilde{A}(X) \tag{2.4}$$

[9] As a result of a misunderstanding on the author's part, the stated theorem is more than is presently known. In fact, one uses only the "moving lemma" of Chow, saying that two cycles can be moved in their classes so that their intersection is not excessive; cf. Chevalley Seminar 1958, *Anneau de Chow et applications.*

(see Chapter I, §3 for the definition of $\widetilde{A}(X)$). The conditions to be verified by a theory of Chern classes are then expressed as follows:

$$\widetilde{C}(E) = \widetilde{C}(E') + \widetilde{C}(E'') \tag{2.5}$$

if the vector bundle E is an extension of E' by E''. If one puts

$$C(E) = \sum_i c^i(E),$$

this condition is expressed by $C(E) = C(E')C(E'')$. Formula (2.5) permits one to extend $\widetilde{C}$ to an additive homomorphism from $K(\xi(X))$ (cf. Chapter I, §2, Example 2) to $\widetilde{A}(X)$:

$$\widetilde{C} : K(\xi(X)) \longrightarrow \widetilde{A}(X), \tag{2.6}$$

and one wants $\widetilde{C}$ to be a λ-homomorphism of λ-rings. This last condition may also be written

$$\widetilde{C}(E \otimes F) = \widetilde{C}(E)\widetilde{C}(F), \qquad \widetilde{C}(\lambda^i E) = \lambda^i \widetilde{C}(E), \tag{2.7}$$

for two vector bundles E and F; of course $\widetilde{C}$ is automatically compatible with augmentations. Let D be a divisor on X and let $L(D)$ be the vector bundle it defines. One wants

$$c^1(L(D)) = \ell(D), \qquad c^i(L(D)) = 0 \quad (i > 1), \tag{2.8}$$

where, for any cycle Z, $\ell(Z)$ denotes its class in $A(X)$. Finally, one imposes that the c^i be functorial, i.e. that if f is a morphism from X to Y and E is a vector bundle on Y, then

$$c^i(f^!(E)) = f^*(c^i(E)), \tag{2.9}$$

where $f^!(E)$ is the inverse image of E on X. One may also write (2.9) in the following form: the notion of inverse image of vector bundles defines a λ-homomorphism of augmented λ-rings

$$f^! : K(Y) \longrightarrow K(X),^{10} \tag{2.10}$$

where here one writes $K(X)$ instead of $K(\xi(X))$, and (2.9) means that there is commutativity in the diagram

$$\begin{array}{ccc} K(Y) & \xrightarrow{f^!} & K(X) \\ \Big\downarrow{\scriptstyle \widetilde{C}_Y} & & \Big\downarrow{\scriptstyle \widetilde{C}_X} \\ A(Y) & \xrightarrow[f^*]{} & A(X). \end{array}$$

Here the space on which $\widetilde{C}$ is considered has been put as a subscript.

Theorem 2.2. There exists a theory of Chern classes satisfying conditions (2.5), (2.7), (2.8), and (2.9).

We shall also admit the following proposition.

Proposition 2.3. Let Y be a closed subset of X and let U be its complement. If x is an element of $A(X)$ inducing 0 on U, then there exists a representative of x which is a cycle carried by Y.

Corollary. Let $p = \dim X - \dim Y$. Then, if $i < p$, the homomorphism

$$A^i(X) \longrightarrow A^i(U)$$

is bijective. Every element of the kernel of $A^p(X) \to A^p(U)$ is a linear combination of components of dimension $n - p$ of Y; hence it is proportional to $\ell(Y)$ if Y is irreducible.

[10] The notation $f^!$ used here is in conflict with that used in duality theory (cf., for example, R. Hartshorne, *Residues and Duality*, Lecture Notes in Mathematics, no. 20, Springer, 1966). This is why in this seminar we replace it by the notation f^*.

2. Definition of the Chern classes of coherent algebraic sheaves

Let $\mathcal{C}$ be an abelian category, and let $\mathcal{C}_0$ be a subclass of $\mathcal{C}$. Denote by $K(\mathcal{C}_0)$ the quotient group of the free group generated by the isomorphism classes of elements of $\mathcal{C}_0$ by the subgroup generated by the elements of the form

$$(E) - (E') - (E''),$$

where E is an extension of E' by E'' and $E, E', E'' \in \mathcal{C}_0$. We must suppose that the classes of elements of $\mathcal{C}_0$, for the isomorphism relation, form a set. Denote by $\gamma_{\mathcal{C}_0}(E)$ the class of an object $E \in \mathcal{C}_0$ in $K(\mathcal{C}_0)$, and omit the subscript $\mathcal{C}_0$ when there is no danger of confusion. The group $K(\mathcal{C}_0)$ is the solution of a universal problem relative to functions

$$E \longmapsto f(E)$$

defined on $\mathcal{C}_0$, with values in an arbitrary abelian group A, which are additive in the sense that $f(E) = f(E') + f(E'')$ whenever E is an extension of E' by E''.

Let F be an additive functor from $\mathcal{C}$ to $\mathcal{C}'$ and let $\mathcal{C}'_0$ be a subclass of $\mathcal{C}'$ satisfying the same condition as $\mathcal{C}_0$, such that for every $A \in \mathcal{C}_0$ the $R^q F(A)$ are in $\mathcal{C}'_0$ and are zero for q sufficiently large. We suppose that injective resolutions exist in $\mathcal{C}$, so that the derived functors $R^q F$ of F exist. Then F defines a homomorphism from $K(\mathcal{C}_0)$ to $K(\mathcal{C}'_0)$, still denoted F, by the formula

$$F(\gamma_{\mathcal{C}_0}(E)) = \sum_{i \geq 0} (-1)^i \gamma_{\mathcal{C}'_0}(R^i F(E)). \tag{2.11}$$

More generally, if one has a cohomological functor (F^i) from $\mathcal{C}$ to $\mathcal{C}'$ such that for every $E \in \mathcal{C}_0$ the $F^i(E)$ are in $\mathcal{C}'_0$ and are zero except for a finite number of i, one obtains a homomorphism from $K(\mathcal{C}_0)$ to $K(\mathcal{C}'_0)$. These remarks extend to multifunctors; moreover, the classical spectral sequences give transitivity properties which we shall not make explicit.

In particular, if F is an exact functor, formula (2.11) simplifies to

$$F(\gamma_{\mathcal{C}_0}(E)) = \gamma_{\mathcal{C}'_0}(F(E)). \tag{2.11 bis}$$

This applies in particular if $\mathcal{C} = \mathcal{C}'$, if F is the identity functor, and if $\mathcal{C}_0 \subset \mathcal{C}'_0$; one has a canonical homomorphism from $K(\mathcal{C}_0)$ to $K(\mathcal{C}'_0)$.

Theorem 2.3. Let $\mathcal{C}$ be an abelian category and let $\mathcal{C}_0 \subset \mathcal{C}_1$ be two subclasses such that the isomorphism classes of objects of $\mathcal{C}_1$ form a set. Suppose that the following conditions are satisfied:

(i) For every exact sequence $0 \to A' \to A \to A'' \to 0$ in $\mathcal{C}$ such that A and A'' are in $\mathcal{C}_0$ (respectively $\mathcal{C}_1$), one has $A' \in \mathcal{C}_0$ (respectively $A' \in \mathcal{C}_1$).

(ii) Let $u : A \to B$ and $v : C \to B$, with $A, B, C \in \mathcal{C}_1$ and u surjective. Then there exist $L \in \mathcal{C}_0$ and homomorphisms $u' : L \to C$ and $v' : L \to A$ such that u' is surjective and $vu' = uv'$.

(iii) For every $A \in \mathcal{C}_1$ there exists an integer $d = d(A)$ such that for every left resolution L of A by objects of $\mathcal{C}_0$ one has $Z_d(L) \in \mathcal{C}_0$, where Z_d denotes the cycles in dimension d.

Under these conditions, the canonical homomorphism from $K(\mathcal{C}_0)$ to $K(\mathcal{C}_1)$ is an isomorphism.

Principle of the proof. Let $A \in \mathcal{C}_1$. By (ii) and (iii) there exists a finite resolution L of A by objects of $\mathcal{C}_0$; put

$$\ell(A) = \sum_{i \geq 0} (-1)^i \gamma_{\mathcal{C}_0}(L_i).$$

One shows that the element of $K(\mathcal{C}_0)$ thus constructed is independent of the resolution L chosen. If one has a second resolution L', one "caps" L and L' by a third resolution L'', with surjective homomorphisms from L'' to L and L'; this is possible by (i) and (ii). One is then reduced to proving that $E_{\mathcal{C}_0}(L) = E_{\mathcal{C}_0}(L'')$. But the difference of the two is $E_{\mathcal{C}_0}(N)$, where N is the kernel of the surjective homomorphism from L'' to L; this kernel is in $\mathcal{C}_0$ by (i). Since N is an acyclic complex in all dimensions, $E_{\mathcal{C}_0}(N) = 0$, whence the conclusion. Here $E_{\mathcal{C}_0}(L)$, for a finite complex with values in $\mathcal{C}_0$, denotes the Euler–Poincaré characteristic

$$\sum_i (-1)^i \gamma_{\mathcal{C}_0}(L_i).$$

One proves analogously that the function $\ell : \mathcal{C}_1 \to K(\mathcal{C}_0)$ thus constructed is additive; hence it defines a homomorphism from $K(\mathcal{C}_1)$ to $K(\mathcal{C}_0)$, and it is immediate that this homomorphism is inverse to the canonical homomorphism from $K(\mathcal{C}_0)$ to $K(\mathcal{C}_1)$. QED.

Remark. To verify (ii), it is enough to verify that $\mathcal{C}_0$ is contained in a subclass $\mathcal{C}_2$ of $\mathcal{C}$ satisfying the two conditions

(ii a) every $A \in \mathcal{C}_1$ is isomorphic to a quotient of an $L \in \mathcal{C}_2$;

(ii b) if $u : A \to B$, with $A, B \in \mathcal{C}_2$, then $\operatorname{Ker} u \in \mathcal{C}_1$.

Corollary. Let X be a quasi-projective algebraic space. Let $\mathscr{F}(X)$ be the category of coherent algebraic sheaves on X, let $\xi(X)$ be the category of coherent locally free algebraic sheaves, equivalently vector bundles on X, and let $\mathscr{F}_0(X)$ be the category of coherent algebraic sheaves F such that, for every $x \in X$, the stalk F_x is an $\mathcal{O}_x$-module of finite cohomological dimension. Thus $\xi(X) \subset \mathscr{F}_0(X) \subset \mathscr{F}(X)$. Then the canonical homomorphism

$$K(\xi(X)) \longrightarrow K(\mathscr{F}_0(X)) \tag{2.12}$$

is an isomorphism.

We verify the conditions of Theorem 2.3. Conditions (i) and (iii) follow from the definition of cohomological dimension and from the fact that a finite-type projective module over a noetherian local ring $\mathcal{O}_x$ is free. To verify (ii), we shall prove that $\mathcal{C} = \mathscr{F}(X)$ satisfies conditions (ii a) and (ii b) of the remark. The second is trivial; therefore it remains to prove the following result.

Proposition 2.4 (Serre). Let X be a quasi-projective algebraic space. Then every coherent algebraic sheaf on X is isomorphic to the quotient of a locally free algebraic sheaf.

This proposition is true if X is a closed subset of projective space by [2], since, for n large enough, $F(n)$ is generated by its sections, which means that F is a quotient of $\mathcal{O}(-n)^k$. In the general case, X is an open subset of a closed subset of a projective space, and it suffices to use the following result, due to Cartier and Serre in particular cases.

Proposition 2.5. Let F be a coherent algebraic sheaf on an open subset U of an algebraic space X. Then F is isomorphic to the restriction of a coherent algebraic sheaf on X.

By applying Zorn's lemma to the opens containing U on which one can extend F, one is reduced to the case where X is affine. Let $\overline{F}$ be the algebraic sheaf on X whose sections on an open V are the sections of F on $U \cap V$. One checks easily that $\overline{F}$ is quasi-coherent, i.e. defined on every affine open V—hence here on all of X—by a module, not necessarily of finite type, over the coordinate ring of that open. This is immediate if U itself is affine, since $\overline{F}$ is then defined on the open V by $\Gamma(U \cap V, F)$ considered as a module over $\Gamma(V, \mathcal{O}_X)$. In the general case, U is a finite union of affine opens U_i, hence $\overline{F}$ is the kernel of the evident homomorphism of quasi-coherent sheaves

$$\prod_i \overline{F}|_{U_i} \longrightarrow \prod_{i,j} \overline{F}|_{U_i \cap U_j},$$

and is therefore itself quasi-coherent. Since X is affine, $\overline{F}$ is generated by its sections. Since $\overline{F}|_U = F$ is coherent, there exists a finite number of sections of $\overline{F}$ which generate F on U. These sections generate a coherent subsheaf of $\overline{F}$ whose restriction to U is isomorphic to F. QED.

Now suppose that X is nonsingular and quasi-projective. By the theorem on syzygies, one has, with the notation of the corollary to Theorem 2.3,

$$\mathscr{F}_0(X) = \mathscr{F}(X).$$

In this case, therefore,

$$K(\xi(X)) = K(\mathscr{F}(X)). \tag{2.13}$$

One may express this isomorphism as follows.

Corollary 2 to Theorem 2.3. Let X be a nonsingular quasi-projective variety. For every abelian group A, there is a one-to-one correspondence between additive functions f of vector bundles on X with values in A, and additive functions g of coherent algebraic sheaves on X with values in A. To every f there corresponds the unique g such that

$$f(E) = g(\mathcal{O}_X(E)) \tag{2.14}$$

for every vector bundle E on X, where $\mathcal{O}_X(E)$ denotes the sheaf of germs of regular sections of E on X.

To compute $g(F)$ for an arbitrary coherent algebraic sheaf, one considers a finite resolution of F by sheaves of the form $\mathcal{O}_X(E_i)$, and one then has

$$g(F) = \sum_i (-1)^i f(E_i). \tag{2.14 bis}$$

In particular, if X is connected, in §1 we considered an additive function $\widetilde{C}(E)$ of the vector bundle E, with values in the group $A = \widetilde{A}(X)$. We deduce from it an additive function of coherent sheaves, say $\widetilde{C}(F)$, and, by passing to components, functions

$$F \longmapsto c^i(F) \in A^i(X).$$

The $c^i(F)$ are called the *Chern classes of the coherent sheaf* F. Theoretically they are computed from the Chern classes of vector bundles by (2.14 bis), with the understanding that in the second member one must pass to multiplicative notation. As for the component of $\widetilde{C}(F)$ in $\mathbb{Z}$, it is the rank of the sheaf F, corresponding to the rank of a module over an integral domain: if X is affine, to which one can always reduce, F is defined by a finite-type module over the coordinate ring of X, and one takes the rank of this module.

3. Functorial generalities on $K(X)$

If X is an algebraic space, put, for brevity,

$$K(X) = K(\mathscr{F}(X)).$$

When X is nonsingular and quasi-projective, identify this group with $K(\xi(X))$ by the corollary 2 to Theorem 2.3. Since $K(\xi(X))$ is not only an abelian group but a λ-ring, it follows by transport of structure that $K(X)$ is also a λ-ring, and is therefore provided with a multiplicative structure and operations λ^i. It is important to define these structures directly, without passing through vector bundles; this will be done below.

If E is a vector bundle on X, denote by $\gamma(E)$ its class in $K(X)$. If F is a coherent algebraic sheaf on X, $\gamma(F)$ denotes in the same way its class in $K(X)$. If Y is an irreducible subvariety of

X, put $\gamma(Y) = \gamma(\mathcal{O}_Y)$, where $\mathcal{O}_Y$ denotes the sheaf of local rings of Y, considered as a coherent algebraic sheaf on X. By linearity, one defines the symbol $\gamma(Y)$ when Y is any cycle on X. When there is risk of confusion, one writes γ_X for γ.

Let X be an arbitrary algebraic space. We introduce on $K(X)$ a filtration, denoting by $K(X)^i$ the subgroup of $K(X)$ generated by the $\gamma(F)$ with

$$\dim \operatorname{Supp} F \leq n - i,$$

where n is the dimension of X. From Serre's dévissage lemma, in the form given in [3], follows the following result.

Proposition 2.6. The group $K(X)^i$ is generated by the $\gamma(Y)$, where Y runs through the subvarieties of dimension $n - i$ of X. If X is irreducible, then $\mathrm{Gr}^0(K(X)) = \mathbb{Z}$.

The latter isomorphism is given by the homomorphism from $K(X)$ to $\mathbb{Z}$ defined with the aid of the notion of rank of a coherent algebraic sheaf.

Now suppose that X is nonsingular. Following the developments at the beginning of §2, define a multiplication in $K(X)$ by putting

$$\gamma(F)\gamma(G) = \sum_{i \geq 0} (-1)^i \gamma(\mathrm{Tor}_i(F, G)), \tag{2.15}$$

the Tor_i being taken, of course, with respect to the local rings of X. The exact sequence of the Tor_i shows that formula (2.15) indeed defines a biadditive map from $K(X) \times K(X)$ to $K(X)$; associativity follows from the spectral sequence of multiple Tors. One also verifies in this way that one can compute the product of several factors by the formula

$$\gamma(F_1) \cdots \gamma(F_n) = \sum_{i \geq 0} (-1)^i \gamma(\mathrm{Tor}_i(F_1, \ldots, F_n)), \tag{2.16}$$

where, in the second member, the Tor_i are simultaneous Tors, computed by simultaneous projective resolution of the arguments F_i.

If in (2.15) one supposes that G is locally free, one finds

$$\gamma(F)\gamma(G) = \gamma(F \otimes G), \tag{2.15 bis}$$

which shows in particular that $\gamma(\mathcal{O}_X)$ is the unit element of $K(X)$, and that the canonical homomorphism from $K(\xi(X))$ to $K(X)$ is a homomorphism of rings.

Formula (2.15) is evidently suggested by Serre's "Tor formula" in intersection theory. This formula proves the second part of the following proposition, the first part following immediately from (2.15) and from a local Tor calculation.

Proposition 2.7. Let X be a nonsingular variety, and let Y and Z be two cycles in X. If Y and Z meet everywhere transversely, then

$$\gamma(Y)\gamma(Z) = \gamma(Y \cdot Z). \tag{2.17}$$

If Y and Z are homogeneous and of respective dimensions $n - i$ and $n - j$, and if they meet without an excessive component, then

$$\gamma_X(Y)\gamma_X(Z) = \gamma_X(Y \cdot Z) \mod K(X)^{i+j+1}. \tag{2.18}$$

One must be careful: equality does not in general hold in (2.18). We shall see in §4 that, if X is nonsingular and quasi-projective, the ring structure of $K(X)$ is compatible with its filtration, and

that the associated graded ring $\mathrm{Gr}(K(X))$ is identified with a quotient of $A(X)$ by a subgroup of torsion, perhaps always zero.[11]

I do not know how to define directly the $\lambda^i(F)$ in terms of sheaves except when the field k has characteristic 0; this is the reason that has prevented us from proving the Riemann–Roch theorem when k is not of characteristic 0. Let F be a coherent algebraic sheaf on X on which the group $\mathfrak{S}_p$ of permutations of p letters operates. Denote by F^{alt} the set of $x \in F$ such that

$$s \cdot x = \varepsilon(s)x$$

for every $s \in \mathfrak{S}_p$, where $\varepsilon(s)$ is the signature of s. It is evidently a coherent algebraic subsheaf of F. This said, one has:

Theorem 2.8. Let X be a nonsingular quasi-projective variety over a field k of characteristic 0. Let F be a coherent algebraic sheaf on X. Then

$$\lambda^p(\gamma(F)) = \sum_{i \geq 0} (-1)^i \gamma\left((\mathrm{Tor}_i(F, F, \ldots, F))^{\mathrm{alt}}\right). \tag{2.19}$$

Here it is clear that the group $\mathfrak{S}_p$ operates on the sheaf $\mathrm{Tor}_i(F, \ldots, F)$.

Principle of the proof. One considers a finite resolution L of F by locally free sheaves L_i, and uses the following general lemma.

Lemma 2.9. Let $L = (L_i)$ be a graded locally free coherent algebraic sheaf with only finitely many nonzero components. In $K(X)$ one has the formula

$$E\left((\otimes^p L)^{\mathrm{alt}}\right) = \lambda^p(E(L)). \tag{2.20}$$

In this formula, $\otimes^p L$ is considered as a sheaf on which the group $\mathfrak{S}_p$ acts, taking the gradings into account; the gradings therefore introduce signs in the usual way, cf. Cartan–Eilenberg. Moreover, if M is a graded coherent algebraic sheaf on X, put

$$E(M) = \sum_i (-1)^i \gamma(M_i).$$

To prove formula (2.20), one is reduced to proving the analogous formula in $K(G)$, where G is an algebraic group, for instance a product of groups $\mathrm{Gl}(n, k)$, and where L is a finite-dimensional G-module over k (cf. Chapter I, §2, Example 2, for the definition of $K(G)$). In that case, this formula has already been used in Theorem 1.4 to show that the second member of (1.33) satisfies the same functional equation as the first member; the verification is elementary. QED.

Let f be a morphism from X to Y, where Y is an algebraic space. The notion of inverse image of vector bundle defines a homomorphism

$$f^! : K(\xi(Y)) \longrightarrow K(\xi(X))$$

of λ-rings. Identifying vector bundles with locally free coherent algebraic sheaves, the notion of inverse image of vector bundle corresponds to the notion of inverse image of algebraic sheaf, already used in [3, no. 8]. When Y is nonsingular, one defines more generally a homomorphism of groups

$$f^! : K(Y) \longrightarrow K(X) \tag{2.21}$$

[11] No: for a counterexample see this seminar, XIV 4.7.

by a formula involving an alternating sum of Tors, inspired by the developments at the beginning of §2, and which the reader will spell out. One then has commutativity in the following diagram:

$$\begin{array}{ccc} K(\xi(Y)) & \xrightarrow{f^!} & K(\xi(X)) \\ \downarrow & & \downarrow \\ K(Y) & \xrightarrow[f^!]{} & K(X), \end{array}$$

which shows in particular, when X and Y are both nonsingular and quasi-projective, that the two definitions of $f^!$ coincide under the identifications of $K(X)$ with $K(\xi(X))$ and of $K(Y)$ with $K(\xi(Y))$.

Another case where one can define a homomorphism (2.21), without Y necessarily nonsingular, is the case where the functor $F \mapsto f^!(F)$ from $\mathscr{F}(Y)$ to $\mathscr{F}(X)$ is exact, i.e. where the local rings of X are flat modules over the local rings of Y. It is enough then to put

$$f^!(\gamma_Y(F)) = \gamma_X(f^!(F)).$$

This case occurs in particular when X is a locally trivial fibre space over Y; to see this, one is reduced to the case of a product $X = Y \times T$. Note that one also verifies that in this case one has $f^!(\mathcal{O}_Z) = \mathcal{O}_{f^{-1}(Z)}$ if Z is an irreducible subvariety of Y, whence

$$f^!(\gamma_Y(Z)) = \gamma_X(f^{-1}(Z)) \tag{2.22}$$

if X is flat over Y. Without this latter condition, formula (2.22) becomes false in general, but one has the following analogue of Proposition 2.7.

Proposition 2.8. Let $f : X \to Y$ be a morphism of nonsingular varieties, and let Z be a cycle on Y. If Z is everywhere transverse to f, formula (2.22) is exact. If Z is homogeneous of codimension i and if $f^{-1}(Z)$ has no excessive component, then

$$f^!(\gamma_Y(Z)) = \gamma_X(f^{-1}(Z)) \mod K(X)^{i+1}. \tag{2.23}$$

The proof is analogous to that of Proposition 2.7.

Finally, let X and Y again be arbitrary algebraic spaces, and let f be a proper morphism from X to Y. For every coherent algebraic sheaf F on X, the direct image sheaf $f_*(F)$ is coherent algebraic, and the same holds more generally for the sheaves $R^i f_*(F)$ (cf. [3]). Recall that, by definition, $R^i f_*(F)$ is the sheaf on Y associated with the presheaf which sends an open U to the group $H^i(f^{-1}(U), F)$; in particular

$$R^0 f_*(F) = f_*(F), \qquad R^q f_*(F) = 0 \quad (q > \dim X), \tag{2.24}$$

and moreover

$$\Gamma(U, R^q f_*(F)) = H^q(f^{-1}(U), F) \tag{2.25}$$

if the open U is affine. According to §2, one defines a homomorphism from $K(X)$ to $K(Y)$, still denoted f_*, by the formula

$$f_*(\gamma(F)) = \sum_{q=0}^{\infty} (-1)^q \gamma(R^q f_*(F)). \tag{2.26}$$

Thus $K(X)$ becomes a covariant functor in X relative to proper morphisms. The relation $(fg)_* = f_* g_*$, just like the relation $(fg)^! = g^! f^!$ which we forgot to mention in its place, is a

particular case of the transitivity relations alluded to in §2 and which follow from the spectral sequences of composed functors.

Let us note the following formula, valid for Y nonsingular and particularly easy to verify when Y is also quasi-projective by taking for y the class of a vector bundle on Y:

$$f_*(x \cdot f^!(y)) = f_*(x) \cdot y \qquad (x \in K(X),\ y \in K(Y)). \tag{2.27}$$

In the particular case where the inverse images of the points of Y by f are finite and contained in an affine open,[12] one checks that the functor $F \mapsto f_*(F)$ is exact and that $R^q f_*(F) = 0$ for $q > 0$. In this case, therefore, $f_*(\gamma_X(F)) = \gamma_Y(f_*(F))$. In particular, if X is an algebraic subspace of Y and if i is the canonical injection of X into Y, then

$$i_*(\gamma_X(F)) = \gamma_Y(F), \tag{2.28}$$

where, in the second member, F is considered as a sheaf on Y which is zero outside X.

4. Some technical results

Let X be an algebraic space. We have seen in §3 that the projection p from $X \times k$ to X defines a homomorphism

$$p^! : K(X) \longrightarrow K(X \times k). \tag{2.29}$$

Proposition 2.9. The homomorphism (2.29) is surjective.

We argue by induction on $n = \dim X$. The assertion is trivial if $n < 0$; suppose $n \geq 0$. By Proposition 2.6, it is enough to verify that for every irreducible closed subset Y of $X \times k$, $\gamma(Y)$ is in the image of $p^!$. It is enough to continue the reasoning by supposing X irreducible. If $p(Y)$ is not dense in X, our assertion follows from the induction hypothesis. Otherwise, either $Y = X \times k$ and the assertion is trivial, or Y is a hypersurface in $X \times k$. Let U be an affine open of X formed of nonsingular points. If D is the divisor on $U \times k$ induced by Y, one knows by commutative algebra that it is linearly equivalent to a divisor of the form $D' \times k$, where D' is a divisor on U. Then

$$\gamma_{U\times k}(D) - \gamma_{U\times k}(D' \times k)$$

belongs to $K(U \times k)$[2] by the corollary to Proposition 2.10, and by what has already been proved this element is of the form $p^!(x')$ with $x' \in K(U)$. Thus

$$\gamma_{U\times k}(D) = p^!(x' + \gamma_U(D')),$$

but x' is the restriction of an element y of $K(X)$ by Proposition 2.10, and consequently the restriction of $\gamma_{X\times k}(D) - p^!(y)$ to $U \times k$ is zero. By Proposition 2.10, $\gamma_{X\times k}(D) - p^!(y)$ comes from an element of

$$K(X \times k - U \times k) = K(X' \times k), \qquad X' = X - U.$$

The proof is finished by applying the induction hypothesis again. QED.

Corollary. Let X be an algebraic space and let p be the projection from $X \times k^n$ to X. Then the homomorphism

$$p^! : K(X) \longrightarrow K(X \times k^n)$$

is surjective; it is even bijective if X is nonsingular.

[12] This latter condition is evidently a consequence of the first, something the author still did not know in 1957!

The first assertion is by induction on n. For the second, put $f(x) = (x, 0)$, whence $pf = 1$ and $f^! p^! = 1$, which proves that $p^!$ is injective.

Proposition 2.10. Let X be an algebraic space, let U be an open subset of X, and let Y be its complement in X. Then the sequence of natural homomorphisms

$$K(Y) \longrightarrow K(X) \longrightarrow K(U) \longrightarrow 0 \tag{2.30}$$

is exact.

N.B. Compare with Proposition 2.3.

The fact that $K(X) \to K(U)$ is surjective follows at once from Proposition 2.5, or also from Proposition 2.6. It remains to prove that if $x \in K(X)$ has zero restriction in $K(U)$, then it is in the image of $K(Y)$. For this, return to the explicit definition of $K(X)$ and $K(U)$. There are two coherent algebraic sheaves F and G on X with

$$x = \gamma_X(F) - \gamma_X(G)$$

and

$$\gamma_U(F) - \gamma_U(G) = 0.$$

This latter relation means that one can find coherent sheaves P' and Q' on U, provided with filtrations whose factors are pairwise isomorphic on U, and such that one has an isomorphism on U

$$P = F + Q' \longrightarrow Q = G + P'.$$

By Proposition 2.5, the sheaves P' and Q' are restrictions to U of coherent sheaves on X, denoted by the same letters; in the same way, their filtrations come from filtrations on the corresponding sheaves on X, by Lemma 2.11 below. One then has

$$\gamma_X(F) - \gamma_X(G) = (\gamma_X(P) - \gamma_X(Q)) + (\gamma_X(P') - \gamma_X(Q')).$$

Introducing the factors P_i and Q_i of the filtrations of P' and Q' on X, the last term is the sum of terms $\gamma_X(P_i) - \gamma_X(Q_i)$, where $P_i|_U \simeq Q_i|_U$. We are thus reduced to proving the following particular case: if R and S are coherent sheaves on X such that $R|_U \simeq S|_U$, then $\gamma_X(R) - \gamma_X(S)$ is in the image of $K(Y)$. Let T be the graph of the given isomorphism from $R|_U$ to $S|_U$; it is a coherent subsheaf of $(R \times S)|_U$, hence by Lemma 2.11 it is the restriction to U of a coherent subsheaf, again denoted T, of $R \times S$. Then

$$\gamma_X(R) - \gamma_X(S) = (\gamma_X(R) - \gamma_X(T)) - (\gamma_X(S) - \gamma_X(T)),$$

and it is enough to prove, for instance, that the first term of the second member is in the image of $K(Y)$. But the projection $u : T \to R$ is an isomorphism over U, hence

$$\gamma_X(R) - \gamma_X(T) = \gamma_X(\operatorname{Coker} u) - \gamma_X(\operatorname{Ker} u),$$

and $\operatorname{Ker} u$ and $\operatorname{Coker} u$ have support in Y.

It remains, then, to prove the following lemma.

Lemma 2.11. Let X be an algebraic space, let F be a coherent algebraic sheaf on X, let U be an open subset of X, and let G be a coherent subsheaf of $F|_U$. Then G is the restriction to U of a coherent subsheaf of F.

Let $\overline{G}$ be the subsheaf of F whose sections on an open V of X are the sections of F on V whose restriction to $U \cap V$ is a section of G. Everything amounts to proving that this sheaf $\overline{G}$ is coherent. For this one may suppose X and U affine, because U is a union of affine opens U_i

and $\overline{G}$ is then the intersection of the analogous sheaves $\overline{G|U_i}$. Then the coordinate ring of U is a ring of fractions A_S of the coordinate ring A of X, and one immediately verifies that if F is defined by the A-module M, then $F|_U$ is defined by the A_S-module

$$M_S = A_S \otimes_A M.$$

The subsheaf G of $F|_U$ is then defined by a submodule N' of M_S, and one sees that $\overline{G}$ is precisely defined by the submodule N of M, inverse image of N' under the canonical homomorphism from M to M_S. QED.

Corollary 1 to Proposition 2.10. Let $x \in K(X)$. Then $x \in K(X)^i$ if and only if there exists a closed subset Y of X, of dimension $\leq n - i$, such that the restriction of x to $X - Y$ is zero.

Corollary 2. Suppose X is connected of dimension n, with no singularities in dimension $n - 1$. If D and D' are two linearly equivalent divisors on X, then

$$\gamma(D) = \gamma(D') \mod K(X)^2.$$

By Corollary 1, one may suppose X nonsingular. The corollary then follows from the general formula

$$\gamma(D) = 1 - \gamma(L(-D)) \mod K(X)^2, \tag{2.31}$$

where $L(-D)$ denotes the rank-one vector bundle defined by the divisor $-D$. To verify (2.31), one writes it in the form

$$\gamma(L(-D)) = 1 - \gamma(D) \mod K(X)^2, \tag{2.31 bis}$$

and notes that the two members are homomorphisms from the group of divisors to the multiplicative group of invertible elements of the ring $K(X)/K(X)^2$. Here $K(X)^1/K(X)^2$ has square zero, which is very easily verified on the explicit formula (2.15), using Corollary 1. Thus one is reduced to the case where D is an irreducible hypersurface. More generally, if D is a hypersurface whose components are disjoint, one has the equality

$$\gamma(D) = 1 - \gamma(L(-D)), \tag{2.32}$$

as follows from the exact sequence of sheaves

$$0 \longrightarrow \mathcal{O}_X(L(-D)) \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{O}_D \longrightarrow 0.$$

Theorem 2.12. Let X be a nonsingular quasi-projective variety, and let Z and Z' be two homogeneous cycles of codimension p on X which are linearly equivalent. Then

$$\gamma_X(Z) = \gamma_X(Z') \mod K(X)^{p+1}. \tag{2.33}$$

By hypothesis, one can find a cycle Y of dimension $n - p + 1$ on $X \times k$ (n being the dimension of X), and two points $a, a' \in k$, such that

$$Z = Y \cdot (X \times a), \qquad Z' = Y \cdot (X \times a').$$

By formula (2.23), one then has

$$\gamma_X(Z) = i_a^!(\gamma_{X\times k}(Y)) \mod K(X)^{p+1},$$

and an analogous formula for $\gamma_X(Z')$. It is therefore enough to prove that $i_a^! = i_{a'}^!$, which follows at once from Proposition 2.9. QED.

Corollary 1. The filtration of $K(X)$ is compatible with its ring structure, i.e. one has

$$K(X)^i K(X)^j \subset K(X)^{i+j}$$

for all integers $i, j \geq 0$. Moreover there is a natural surjective homomorphism of graded rings

$$\varphi : A(X) \longrightarrow \mathrm{Gr}(K(X)), \tag{2.34}$$

where the second member denotes the graded ring associated with $K(X)$, provided with the filtration $(K(X)^i)_{i\geq 0}$, defined by the condition

$$\varphi(\ell(Z^{n-p})) = \gamma(Z^{n-p}) \mod K(X)^{p+1}.$$

This corollary follows immediately from Theorem 2.12, Propositions 2.6 and 2.7, and Chow's theorem 2.1, by induction on the integer $i + j$.

Corollary 2. Let X and Y be two nonsingular quasi-projective varieties and let f be a morphism from X to Y. Then the homomorphism $f^!$ from $K(Y)$ to $K(X)$ is compatible with the filtrations, and one has a commutative diagram

$$\begin{array}{ccc} A(Y) & \xrightarrow{\varphi_Y} & \mathrm{Gr}(K(Y)) \\ {\scriptstyle f^*}\downarrow & & \downarrow{\scriptstyle \mathrm{Gr}(f^!)} \\ A(X) & \xrightarrow[\varphi_X]{} & \mathrm{Gr}(K(X)). \end{array}$$

Using the graph of f, decompose f as the product of an immersion of X into $X \times Y$ and of a projection of $X \times Y$ onto Y. For the latter the corollary is trivial, and for an immersion one proceeds as for Corollary 1, using Proposition 2.8 in place of Proposition 2.7.

Proposition 2.13 ("cellular decomposition"). Let P be an algebraic space, irreducible or not, provided with an increasing family

$$P^0 \subset P^1 \subset \cdots \subset P^n = P$$

of closed subsets, such that for every i with $0 \leq i \leq n$, the connected components of $P^i - P^{i-1}$ are algebraic spaces $V_{i,\alpha}$ isomorphic to k^i; put $P^{-1} = \varnothing$. Then:

a) For every algebraic space X, the natural map from $K(X) \otimes K(P)$ to $K(X \times P)$, deduced from the tensor product of sheaves on X and P, is surjective.

b) The $\gamma_P(V_{i,\alpha})$ form a system of generators of the group $K(P)$.

The proof is by induction on n, using the corollary to Proposition 2.9 and Proposition 2.10. N.B. Unfortunately, I do not know whether the $\gamma_P(V_{i,\alpha})$ form a basis of $K(P)$ or whether the homomorphism considered in a) is bijective. We shall not need to know this below.

Theorem 2.14. Let x_i $(1 \leq i \leq q)$ and E_j $(1 \leq j \leq r)$ be letters, and let n_j $(1 \leq j \leq r)$ be positive integers. Consider the symbols $\lambda^k(x_i)$ with $k \geq 1$ and $\lambda^k(E_j)$ with $1 \leq k \leq n_j$ as indeterminates, and let R be a polynomial with integral coefficients in these indeterminates. Suppose that, for every graded ring A, when one substitutes in R elements ξ_i for the x_i and elements

$$\eta_j = [n_j, 1 + \eta_j^{(1)} + \cdots + \eta_j^{(n_j)}]$$

of $\widetilde{A}$ for the E_j, subject to the restrictions $\varepsilon(\xi_i) = 0$ and $\eta_j^{(k)} = 0$ for $k > n_j$, one has

$$R((\lambda^k(\xi_i)), (\lambda^k(\eta_j))) \in \widetilde{A}^p.$$

Then, if X is an irreducible nonsingular quasi-projective variety, for arbitrary elements x'_i of $K(X)$[1] and vector bundles E'_j of dimension n_j on X $(1 \leq i \leq q,\ 1 \leq j \leq r)$, one has

$$R((\lambda^k(x'_i)), (\lambda^k(\gamma(E'_j)))) \in K(X)^p. \qquad (*)$$

Proof. By §2, the x'_i are themselves differences of elements of the form $\gamma(E)$, with E a vector bundle. On the other hand, assuming X locally closed in a projective space P, it follows from §2 and Proposition 2.5 that, for every $F \in \mathscr{F}(X)$, the sheaf $F(n)$ is generated by its sections for n sufficiently large. If F is defined by a vector bundle E, this proves that $E(n)$ is the inverse image of the canonical vector bundle on a Grassmannian variety G by a morphism from X to G. Considering the corresponding morphism from X to $P \times G$, one sees that F is the inverse image of a vector bundle on $P \times G$. Applying this to all vector bundles which occur, and using Corollary 2 to Theorem 2.12, we are reduced to the case where X is a product of Grassmannians. In this case the conclusion will follow from the following lemma.

Lemma 2.15. Suppose that X is a product of Grassmannians. Then one can find a λ-homomorphism from $K(X)$ to a torsion-free λ-ring of the form $\widetilde{A}$, where A is a graded ring, compatible with filtrations, and such that the corresponding homomorphism $\mathrm{Gr}(K(X)) \to \mathrm{Gr}(A)$ is injective.

To prove the lemma, we shall use Chow's theory of Chern classes. If one could prove the lemma, or Theorem 2.14 directly, one would deduce a purely "sheaf-theoretic" theory of Chern classes; cf. §5.

We shall consider the homomorphism $\widetilde{C}$ from $K(X)$ to $\widetilde{A}(X)$ and put $A = A(X)$. It remains to prove that the homomorphism $\psi = \mathrm{Gr}(\widetilde{C})$ from $\mathrm{Gr}(K(X))$ to $\mathrm{Gr}(A(X)) \simeq A(X)$ is injective. The fact that $\widetilde{C}$ is compatible with filtrations is true for every nonsingular quasi-projective variety and follows easily from the corollary to Proposition 2.3. On the other hand, since X is a product of Grassmannians G_j, there are vector bundles E_j on X, inverse images of the canonical bundles on the factors. We shall use the following known facts:

a) On X, linear equivalence of cycles is equivalent to numerical equivalence, and $A(X)$ is a group of finite rank.

b) The $c^i(E_j)$ generate the ring $A(X)$.

From a) it follows that

$$\varphi : A(X) \longrightarrow \mathrm{Gr}(K(X))$$

is injective, and hence bijective, by the following lemma.

Lemma 2.15. Let X^n be a nonsingular projective variety and let Z^{n-p} be a cycle on X such that $\varphi(Z) \in \mathrm{Gr}^p(K(X))$ is zero. Then Z^{n-p} is numerically equivalent to zero.

To prove this lemma, it suffices to use the additive function

$$\chi(F) = \sum_{i \geq 0} (-1)^i \dim H^i(X, F)$$

and the fact that this function is equal to 1 for $F = \mathcal{O}_{(x)}$ for every $x \in X$.

Thus, in the case under consideration, $A(X)$ and $\mathrm{Gr}(K(X))$ have the same finite rank in every degree, and $\mathrm{Gr}(K(X))$ is torsion-free, since this is true of $A(X)$. From assertion b) above it follows, in a formal way, that the map $\widetilde{C}$ from $K(X)$ to $\widetilde{A}(X)$ is surjective modulo finite groups. Since $\mathrm{Gr}(K(X))$ and $A(X)$ have the same finite rank in every degree, it then follows easily that the homomorphism $\mathrm{Gr}(\widetilde{C})$ from $\mathrm{Gr}(K(X))$ to $\mathrm{Gr}(\widetilde{A}(X))$ is bijective modulo finite

groups in every degree; one uses induction on the degree. Since $\mathrm{Gr}(K(X))$ is torsion-free, this homomorphism $\mathrm{Gr}(\widetilde{C})$ is therefore injective. QED.

N.B. The homomorphism $\widetilde{C}$ is not surjective in general, even if X is a projective space of dimension 2.

5. Sheaf-theoretic definition of Chern classes. Application to the study of injection morphisms

Theorem 2.16. Let X be a nonsingular quasi-projective variety. Then, for every $x \in K(X)$ and every integer $i \geq 0$, the element $\gamma^i(x - \varepsilon(x))$ is of filtration $\geq i$. Let $c^i(x) \in \mathrm{Gr}^i(K(X))$ be the class of this element modulo $K(X)^{i+1}$. If one puts

$$\widetilde{c}(x) = \left[\varepsilon(x), 1 + \sum_{i \geq 0} c^i(x)\right] \in \mathrm{Gr}\widetilde{(K(X))},$$

then $\widetilde{c}$ satisfies conditions analogous to those of Theorem 2.2.

The first assertion follows from Theorem 2.14, as does the fact that $x \mapsto \widetilde{c}(x)$ is a homomorphism of λ-rings; formula (1.25) implies $\gamma_t(x + y) = \gamma_t(x)\gamma_t(y)$, which already shows that $\widetilde{c}$ is an additive homomorphism. The functoriality of $\widetilde{c}$ is verified immediately, and (2.8) follows from (2.31). QED.

Corollary 1. One has

$$c^i(x) = \varphi(c^i(x)).$$

This follows from a uniqueness theorem for Chern classes, proved as in Hirzebruch by passage to flag varieties. One only has to show that, if Y is a flag variety associated with a vector bundle on X, then $\mathrm{Gr}(K(X)) \to \mathrm{Gr}(K(Y))$ is injective; this is verified by the explicit determination of $K(Y)$, with all its structures, from $K(X)$. I shall not give the details here.

Corollary 2. Suppose that for every element $Z \in A(X)$ there exists a morphism f from X to a product X' of Grassmannians such that Z is in the image of f^*. Then the canonical homomorphisms

$$\varphi : A(X) \longrightarrow \mathrm{Gr}(K(X)), \qquad \psi : \mathrm{Gr}(K(X)) \longrightarrow A(X)$$

satisfy, in dimension i, the relations

$$\psi\varphi = (-1)^{i-1}(i-1)!\,1, \qquad \varphi\psi = (-1)^{i-1}(i-1)!\,1. \tag{2.35}$$

Since φ is surjective, it is clearly enough to prove the first formula, and for this one may suppose that X is a product of Grassmannians. Since then φ is injective, it is enough to prove the second formula (2.35), which by Corollary 1 is written

$$\gamma^i(x - \varepsilon(x)) = (-1)^{i-1}(i-1)!\,x \mod K(X)^{i+1}$$

for every $x \in K(X)^i$. Since ψ is injective, it is enough to prove the analogous relation for $\widetilde{C}(x) \in A(X)^i$, and this is then a consequence of (1.22 bis).

Remark. Corollary 2 makes plausible the validity of (2.35) in all cases; there should exist a direct proof of it. In every case one proves easily the second formula (2.35) modulo the torsion subgroup of $\mathrm{Gr}(K(X))$, and in characteristic 0 this same formula is a consequence of the Riemann–Roch theorem. The interest of (2.35), when true, lies in the fact that it shows that φ is injective modulo torsion groups, perhaps always zero. Thus one does not lose much by

defining Chern classes as elements of $\mathrm{Gr}(K(X))$. If one tensors with $\mathbb{Q}$, as will be done later for the Riemann–Roch theorem, the two definitions of Chern classes would then be identical.

Let X still be nonsingular and quasi-projective. Let in addition Y be a nonsingular subvariety of X, and let i be the injection of Y into X. For i_* and $i^!$ one then has the following formulas:

(i) $i^!$ is a homomorphism of λ-rings.

(ii) $i_*(x \cdot i^!(y)) = i_*(x) \cdot y$, whence in particular

$$i_* i^!(y) = \xi y, \qquad \text{with } \xi = i_* i^!(1) = \gamma_X(N).$$

(iii) $i^! i_*(x) = x \cdot \lambda_{-1}(N)$, whence in particular

$$i^!(\xi) = i^! i_*(1) = \lambda_{-1}(N).$$

(iv) $i_*(x) i_*(x') = i_*(x x' \lambda_{-1}(N))$.

Here, by definition, N is the class in $K(Y)$ of the conormal bundle of Y in X. Formulas (i) and (ii) are true for arbitrary morphisms, not necessarily injections, and (iii) and (iv) are verified from the definition (2.15) and the analogous formula for inverse images, taking x and x' to be classes of vector bundles and using the fact that

$$\mathrm{Tor}(\mathcal{O}_Y, \mathcal{O}_Y) = \Lambda(N). \tag{2.36}$$

Formula (iv) expresses that i_* is a homomorphism of rings if one introduces on $K(Y)$ a new multiplicative structure, by the definition

$$x \cdot_N x' = x x' \lambda_{-1}(N)$$

(cf. Chapter I, §4). It is completed by the formula

(v) $i_*(\lambda^p(N, x)) = \lambda^p(i_*(x))$ for $p \geq 1$,

which means that i_* defines a λ-homomorphism from $K(Y)_N$ into $K(X)$. This formula (v), certainly true in all cases, is for the moment proved only in characteristic 0, because it follows from the conjunction of Theorems 1.4 and 2.8.

There are analogous formulas for i_* and i^*:

(i bis) i^* is a homomorphism of graded rings.

(ii bis) $i_*(x \cdot i^*(y)) = i_*(x) y$, whence in particular

$$i_* i^*(y) = \xi' y, \qquad \text{with } \xi' = i_*(1).$$

(iii bis) $i^* i_*(x) = x \cdot (-1)^q N^q$, whence in particular

$$i^*(\xi') = (-1)^q N^q.$$

(iv bis) $i_*(x) i_*(x') = i_*(x x' (-1)^q N^q)$.

(v bis) i_* increases degrees by q units.

In these formulas, q is the codimension of Y in X, and one puts $N^i = c^i(N)$. Only formulas (iii bis) and (iv bis) require proof. I do not know whether they are well known, or even whether they are true, and I confine myself to noting that they follow by reduction from formulas (ii) and (iv), provided one works in $\mathrm{Gr}(K(Y))$ and $\mathrm{Gr}(K(X))$ and not in $A(Y)$ and $A(X)$. One then uses the fact that i_* and i^* come by passage to the quotient from i_* and $i^!$, noting that i_* shifts the filtration by q units.

All universal formulas relating i_* and $i^!$, respectively i_* and i^*, are formal consequences of the preceding formulas, as one can convince oneself without great difficulty.

Formula (v) gives

$$i_*(\gamma^p(N,x)) = \gamma^p(i_*(x)).$$

The conjunction of Theorem 2.14 and Proposition 1.5 shows that $\gamma^p(N,x)$, for $p = q + j$, is of filtration $\geq j$. If one denotes by $G_{q,j}(N,x)$ its class in $\mathrm{Gr}^j(K(Y))$, Theorem 2.16 shows that

$$i_*(G_{q,j}(N,x)) = c^p(i_*(x)).$$

Finally, Proposition 1.5 joined with Theorem 2.14 permits one to express $G_{q,j}(N,x)$ as a polynomial with integral coefficients in the $c^i(N)$, the $c^i(x)$, and $\varepsilon(x)$. One deduces the following theorem.

Theorem 2.17. Suppose the field k has characteristic 0, and let $i : Y \to X$ be an injection morphism of nonsingular quasi-projective varieties. Then one has formulas (i) to (v), and moreover, for every integer $j \geq 0$, the formula

$$c^{q+j}(i_*(x)) = i_*\left(\left(\frac{\widetilde{c}(x) * \lambda_{-1}(\widetilde{c}(N))}{(-1)^q N^q}\right)^{(j)}\right). \tag{2.37}$$

The second member of formula (2.37) is an abbreviated way of denoting the polynomial in the components of $\widetilde{c}(x)$ and $\widetilde{c}(N)$ described in Proposition 1.5.

Corollary. Under the preceding conditions one has

$$\mathrm{ch}(\widetilde{c}(i_*(x))) = i_*\left(\mathrm{ch}(\widetilde{c}(x))\,\mathfrak{C}(\check{N})^{-1}\right), \tag{2.38}$$

where ch is the Chern homomorphism defined by formula (1.26).

It is enough to use (2.37) written in the form

$$\widetilde{c}(i_*(x)) = 1 + i_*\left(\frac{\widetilde{c}(x) * \lambda_{-1}(\widetilde{c}(N)) - 1}{(-1)^q N^q}\right), \tag{2.37 bis}$$

the explicit formula (1.29), formula (iv bis), and finally (1.30).

One may write (2.38) in the form

$$\mathrm{ch}_X(F) = i_*\left(\mathrm{ch}_Y(F)\,\mathfrak{C}(T_{X/Y})^{-1}\right), \tag{2.38 bis}$$

where F is a coherent algebraic sheaf on Y (considered in the first member as a sheaf on X which is zero outside Y), where ch_X and ch_Y are the Chern homomorphisms taken respectively on X and Y, and where $T_{X/Y}$ is the normal bundle of Y in X.

Remarks. Contrary to (2.38), formula (2.37) is a "formula without denominators". It has been proved, even in characteristic 0, only by placing oneself in $\mathrm{Gr}(K(X))$ and not in $A(X)$, which may not be the same thing. It is certainly true in every characteristic and in $A(X)$. Let us note that one verifies at once that the images of the two members by i^* are the same; hence, applying i_*, the product of their difference by N^q is zero. This suggests a completely different

method of proof, by trying to obtain Y as a transverse inverse image of a subvariety Y' in a variety X' such that, in dimension $\leq n = \dim X$, the class of Y' in $A(X')$ is not a divisor of 0. Unfortunately one cannot hope for X' to be a Grassmannian or something close to it.

Note that, if torsion elements are neglected, formula (2.38) is equivalent to (2.37).

6. The Riemann–Roch theorem

Its statement is as follows: let f be a proper morphism from a non-singular quasi-projective variety Y into a variety X of the same kind. Then one has

$$f_*\big(\mathrm{ch}_Y(x)\,\mathfrak{C}(Y)\big) = \mathrm{ch}_X\big(f_!(x)\big)\,\mathfrak{C}(X). \tag{2.39}$$

Both sides are in $A(X)\otimes\mathbb{Q}$, and $\mathfrak{C}(X) = \mathfrak{C}(T_X)$.

This formula makes it possible to compute, up to torsion, the Chern classes of $f_!(x)$ from the Chern classes of x, those of T_X and T_Y, and the homomorphism f_*. Or, equivalently, it makes it possible to determine the homomorphism

$$f_! : K(Y)\otimes\mathbb{Q} \longrightarrow K(X)\otimes\mathbb{Q}$$

when these groups are identified, by means of the homomorphisms ch_Y and ch_X, respectively with $A(Y)\otimes\mathbb{Q}$ and $A(X)\otimes\mathbb{Q}$ (provided that formula (2.35) is true), from f_* and the Chern classes of T_X and T_Y.

I can prove formula (2.39) only in characteristic 0, and as an equality in $\mathrm{G}(K(X))\otimes\mathbb{Q}$. For this, since Y is locally closed in a projective space P, f is decomposed as the product of an injection of Y into $P\times X$ and a projection morphism from $P\times X$ to X, and (2.39) is proved for each of these two morphisms.

For an injection morphism, one sees immediately that formulas (2.38) and (2.39) are equivalent. The characteristic 0 hypothesis enters only through Theorem 2.8, which permits one to express the classes $\lambda^i(\gamma(F))$, for a coherent algebraic sheaf F, by local cohomological invariants of F.

For a projection morphism $f : P\times X \to X$, Proposition 2.13 permits us to suppose that x is of the form $y\otimes z$, with $y\in K(P)$ and $z\in K(X)$. Then the Künneth formula gives

$$f_!(x) = \chi(y)\,z,$$

where, for a coherent algebraic sheaf F on P, one puts

$$\chi(F) = \sum_{i\geq 0}(-1)^i \dim H^i(P,F).$$

One is therefore at once reduced to proving the formula

$$\chi(F) = \pi_r\big(\mathrm{ch}_p(F)\,\mathfrak{C}(P)\big), \tag{2.40}$$

where π_r denotes the component of degree $r = \dim P$. By Proposition 2.13, one may suppose that $F = \mathcal{O}_Q$, where Q is a linear subvariety of P. Then $\chi(F) = 1$, since this is the arithmetic genus of Q; it remains only to see that the second member of (2.40) is 1.

Indeed, if V is a hyperplane of P and if one puts

$$\xi = \gamma_P(\mathcal{O}_V), \qquad L = \ell(V),$$

then

$$1-\xi = \gamma_P(E(-L)),$$

where $E(-L)$ is the vector bundle defined by $-L$. Hence

$$C_p(1-\xi) = [1, 1-L],$$

and consequently

$$\mathrm{ch}_p(1-\xi) = e^{-L}, \qquad \mathrm{ch}_p(\xi) = 1 - e^{-L},$$

and therefore

$$\mathrm{ch}_p(\xi^p) = (1-e^{-L})^p.$$

If p is the dimension of Q in P, one has $\xi^p = \gamma_P(Q)$; hence

$$\mathrm{ch}_p(F)\,\mathfrak{C}(P) = \left(L/(1-e^{-L})\right)^{r+1}(1-e^{-L})^p.$$

It remains to verify that the coefficient of L^r in this formal series in L is 1. This follows from the characteristic property of the formal series $L/(1-e^{-L})$, namely that the coefficient of L^q in $(L/(1-e^{-L}))^{q+1}$ is 1 (put $q = r+1-p$).

Proof of the Riemann–Roch theorem

(Grothendieck, 1 November 1957)

Reminder of notation

These are the notations of the "Report on Riemann–Roch," cited as RRR below.

All varieties considered are non-singular and quasi-projective, that is, isomorphic to a locally closed subvariety of a projective space. The base field is algebraically closed, of arbitrary characteristic.

If X is such a variety, $K(X)$ denotes the abelian group generated by the classes of coherent sheaves on X, modulo the identification coming from an extension into a sum; the alternating sum of Tor makes $K(X)$ a ring. If F is a sheaf, respectively E a vector bundle, respectively Y a subvariety of X, one denotes by $\gamma_X(F)$, respectively $\gamma_X(E)$, respectively $\gamma_X(Y)$, the element of $K(X)$ corresponding to F, respectively to E, respectively to $\mathcal{O}_Y$. In fact, one often writes simply F, E instead of $\gamma_X(F)$.

Let $A(X)$ be the graded ring of classes of cycles on X for rational equivalence (cf. Chow); $A^i(X)$ is formed by the cycles of codimension i. If E is a vector bundle, $C(E) = \sum C^i(E)$, with $C^i(E) \in A^i(X)$, is its Chern class (defined as inverse image of Schubert cycles). By linearity one deduces the classes $C^i(y)$, for all $y \in K(X)$. If

$$C(y) = \prod(1 + a_i),$$

one sets, following Hirzebruch,

$$\mathrm{ch}(y) = \sum e^{a_i}, \qquad T(y) = \prod \frac{a_i}{1-e^{-a_i}}.$$

These are elements of $A(X) \otimes \mathbb{Q}$. When y is the tangent bundle of X, one writes $T(X)$ instead of $T(y)$.

If G is a vector bundle, $\lambda^p G$ denotes its p-th exterior power and

$$\lambda_{-1}(G) = \sum (-1)^p \lambda^p(G);$$

this is an element of $K(X)$.

If f is a proper regular map from a variety Y into a variety X, one defines homomorphisms

$$f^* : A(X) \longrightarrow A(Y), \qquad f_* : A(Y) \longrightarrow A(X).$$

The first is homogeneous of degree 0 and multiplicative. The second is homogeneous of degree $\dim X - \dim Y$. One also defines homomorphisms

$$f^* : K(X) \longrightarrow K(Y), \qquad f_! : K(Y) \longrightarrow K(X).$$

If F is a coherent sheaf on X, $f^*(F)$ is, by definition, the alternating sum of the $\mathrm{Tor}_p^{\mathcal{O}_X}(\mathcal{O}_Y, F)$. For vector bundles, this is simply the inverse-image operation.

If G is a coherent sheaf on Y, $f_*(G)$ is coherent on X. If $R^p f_*$ denotes the p-th derived functor of the functor f_* so defined, one has, by definition,

$$f_!(G) = \sum (-1)^p R^p f_*(G).$$

Riemann–Roch theorem

Let $f : Y \to X$ be a proper morphism (regular map) from a non-singular quasi-projective variety Y into another such variety X, and let $y \in K(Y)$. Then

$$f_*(\mathrm{ch}(y)T(Y)) = \mathrm{ch}(f_!(y))T(X) \quad \text{in } A(X) \otimes \mathbb{Q}. \tag{1}$$

Proof (abridged).

Lemma 1. Consider proper morphisms of varieties

$$Z \xrightarrow{g} Y \xrightarrow{f} X.$$

If the theorem R.R. is true for f and for g, it is true for fg. If it is true for fg and for g, it is true for f. If f_* is injective, and if the theorem R.R. is true for fg and for f, it is true for g.

This is trivial. In fact, when one supposes R.R. true for fg and g, one must still suppose that $g_!$ is surjective in order to be able to assert that R.R. is true for f.

Since a proper morphism is composed of an injection and a projection $X \times P \to X$, where P is a projective space, one is reduced to treating these two cases separately. The second, as was seen above, is reduced to the standard calculation, by means of Proposition 2.13 ("cellular decomposition") of RRR. Thus suppose $Y \subset X$, with injection morphism i. Formula (1) becomes

$$\mathrm{ch}(i_!(y)) = i_*(\mathrm{ch}(y)T(E)^{-1}), \tag{2}$$

where $E = T_{X/Y}$ is the normal bundle of Y in X.

Lemma 2. Suppose that there exists on X a vector bundle G of rank $p = \mathrm{codim}_X Y$, such that

$$\gamma_X(Y) = i_*(1) = \lambda_{-1}(G), \qquad i^*(G) = E, \qquad (-1)^p C^p(G) = Y. \tag{3}$$

If then

$$y = i^*(x), \qquad x \in K(X), \tag{4}$$

formula (2) is valid.

The proof is immediate from the fact that ch is a homomorphism of rings, and that

$$\mathrm{ch}(\lambda_{-1}(G)) = (-1)^p C^p(G)\, T(G)^{-1}. \tag{5}$$

Corollary. R.R. is true if Y is a hypersurface and if y is of the form $i^*(x)$, with $x \in K(X)$.

Lemma 3. Suppose that $X = Y \times P$, where P is a projective space, and that i is the injection $u \mapsto (u, v_0)$, $v_0 \in P$. Then i_* is injective and R.R. is true.

This is pure standard calculation.

Suppose again that X, Y, y are arbitrary, always with $Y \subset X$. Let X' be the variety obtained by blowing up X along Y, and let Y' be the hypersurface inverse image of Y. One has a diagram of maps

$$\begin{array}{ccc} Y' & \xrightarrow{j} & X' \\ {\scriptstyle g}\downarrow & & \downarrow{\scriptstyle f} \\ Y & \xrightarrow[i]{} & X. \end{array}$$

The inverse image of E in Y' admits a subbundle of rank 1, whose dual is denoted L. Moreover L^{-1} is also the restriction to Y' of the line bundle $L(Y')$ defined on X' by the divisor Y'. Put $F = E/L^{-1}$. Elementary computations give the following lemma.

Lemma 4. One has the formulas, where $p = \mathrm{codim}_X Y$:

$$f^* i_!(y) = j_*(\lambda_{-1}(\check{F})y), \tag{6}$$

$$\lambda_{-1}(\check{F}) \equiv \gamma^{p-1}(E)\lambda^p(\check{E}) \pmod{1 - L}, \tag{7}$$

$$f_*(1) = 1, \quad \text{hence } f_* f^* = 1, \tag{8}$$

$$f^* i_*(\alpha) \equiv j_*(\alpha C^{p-1}(F)) \pmod{\mathrm{Ker}\, f_*} \quad \text{for all } \alpha \in A(Y). \tag{9}$$

To simplify notation, $K(Y)$ has been made to operate on $K(Y')$, and $A(Y)$ on $A(Y')$, by the homomorphisms g^*. In formula (7), it seems that $\gamma^{p-1}(E)$ denotes $\lambda^{p-1}(E-2)$, that is,

$$\sum_{i+j=p-1} (\cdots)\lambda^i(E);$$

the congruence takes place in $K(Y')$.

Formula (6) follows from the equality

$$\mathrm{Tor}_i^{\mathcal{O}_X}(\mathcal{O}_Y(v), \mathcal{O}_Y(v')) = \lambda^i \check{F}(v') \quad (v' \in Y',\ v = g(v')). \tag{6 bis}$$

Formula (7) follows from the formulas

$$g_*(L^{-i}) = 0 \quad \text{for } 0 < i \leq p-1, \qquad g_*(1) = 1, \tag{10}$$

themselves consequences of Künneth and of the cohomology of projective spaces.

Formula (8) is trivial. Finally, (9) follows from $g_*(C^{p-1}(F)) = 1$, which is deduced, for example, from the immediate formulas

$$g_*(\xi^i) = 0 \quad \text{if } 0 \leq i < p-1, \qquad g_*(\xi^{p-1}) = 1, \tag{10 bis}$$

with $\xi = C^1(L) \in A^1(Y')$. In fact, (9) is very likely an identity, and not merely a congruence. The unnecessarily complicated formula (7) may be replaced, for example, by VII 4.1.

From formula (7) it follows at once that $\lambda_{-1}(\check{F}) \in j^*(K(X'))$, provided that

$$y\,\gamma^{p-1}(E)\lambda^p(\check{E}) \in i^*(K(X)). \tag{11}$$

Suppose this condition (11) satisfied. By the corollary to Lemma 2, R.R. is true for $(Y', X', y\lambda_{-1}(\check{F}))$. On the other hand, to prove (2), formula (8) reduces the matter to proving that

$$f^*\,\mathrm{ch}(i_!(y)) \equiv f^*\big(i_*(\mathrm{ch}(y)T(E)^{-1})\big) \pmod{\mathrm{Ker}\, f_*}. \tag{12}$$

This last formula is verified immediately, using (6), (9), R.R. for $(Y', X', y\lambda_{-1}(\check{F}))$, and the formula

$$\mathrm{ch}(\lambda_{-1}(\check{F})) = C^{p-1}(F)T(F)^{-1} \tag{13}$$

(cf. formula (5)).

Thus R.R. is proved every time $y\,\gamma^{p-1}(E) = 0$, in particular every time $p - 1 > \dim Y$, since $\gamma^{p-1}(E)$ is of filtration $\geq p-1$ in $K(Y)$, filtered by the codimension of supports; that is, every time

$$\dim Y < \frac{\dim X - 1}{2}.$$

One is reduced to this case by combining Lemma 1 and Lemma 3, taking for P a projective space of sufficiently large dimension, for example $r > \dim X + 1$. This proves the assertion.

Remark. We have used the fact that $\gamma^{p-1}(E)$ was of filtration $\geq p-1$. One can prove this fact directly, without passing through Grassmannians as in RRR, 2.16, by studying the projective bundle associated to E. This method more generally gives Theorem 2.14 of RRR.

Extract from a letter of Grothendieck

"Morally," the new method rests on the determination of $K(X)$ and $A(X)$ when X is either the projective bundle associated to a vector bundle, or a variety obtained by blowing up a non-singular subvariety. In this second case I have not made the complete determination; a small equality is still missing. With the notation of the short note, one must prove formula (9), but as an equality:

$$f^*(i_*(\alpha)) = j_*(\alpha C^{p-1}(F)), \qquad \alpha \in A(Y). \tag{9}$$

One observes that the two members have the same image by f_*, and the same image by j^*, so that the question is equivalent to

$$\mathrm{Ker}\, f_* \cap \mathrm{Ker}\, j^* = 0. \tag{9 bis}$$

In any case, (9) is true after reducing to $G(K(X'))$ (which destroys a little torsion, at most), for it then follows from (6); there is therefore hardly any doubt that it is true.

I also point out that equality (9) follows very easily from (6), without passing through the troublesome (6 bis).

Exposé I. Generalities on finiteness conditions in derived categories

by L. Illusie

0. Introduction

The object of Exposés I to IV is to develop, with the degree of generality appropriate in this Seminar, the formalism of finiteness conditions in derived categories of ringed topoi.

As was said in Exposé 0, the need to define, on arbitrary schemes, "Grothendieck groups" possessing good variance properties forced one to generalize and to soften the finiteness notions used up to now.

A classical notion such as that of a coherent sheaf on a ringed space $(X, \mathcal{O}_X)$ makes sense only when $\mathcal{O}_X$ is coherent. One might think of replacing it by the notion of finite presentation. But this has the inconvenience that the kernel of an epimorphism of modules of finite presentation is no longer, in general, of finite presentation. A satisfactory notion is reached by observing that, when $\mathcal{O}_X$ is coherent, a coherent sheaf F is not only of finite presentation but of n-finite presentation for every $n \in \mathbb{N}$, where n-finite presentation means that locally there exists an exact sequence

$$L_n \longrightarrow L_{n-1} \longrightarrow \cdots \longrightarrow L_0 \longrightarrow F \longrightarrow 0,$$

with the L_i free of finite type. When $\mathcal{O}_X$ is no longer assumed coherent, say that an $\mathcal{O}_X$-module F is *pseudo-coherent* if it satisfies the preceding condition, that is, if it is of n-finite presentation for every n. Then the notion of pseudo-coherence has, with respect to short exact sequences, the same stability property as coherence: if two terms of a short exact sequence of $\mathcal{O}_X$-modules are pseudo-coherent, then so is the third.

The preceding notion is easily generalized to complexes of sheaves. A complex F of $\mathcal{O}_X$-modules is said to be *pseudo-coherent* if it is n-pseudo-coherent for every $n \in \mathbb{Z}$, where n-pseudo-coherent means that there locally exists a quasi-isomorphism $L \to F$, with L a complex bounded above and with components free of finite type in degrees $> n$. For a complex F reduced to degree 0, this is the same as saying that F is pseudo-coherent as a complex or as a module.

The notion of pseudo-coherent complex has excellent stability properties, described in Exposé I, §§1 and 2. First of all it is stable under isomorphism in the derived category $\mathrm{D}(X)$ of the category of $\mathcal{O}_X$-modules; better still, if two objects of a distinguished triangle of $\mathrm{D}(X)$ are pseudo-coherent, then so is the third. In other words, the full subcategory $\mathrm{D}(X)_{\mathrm{coh}}$ of $\mathrm{D}(X)$ formed by pseudo-coherent complexes is a triangulated subcategory. Moreover, pseudo-coherence is preserved under inverse image and derived tensor product. In the case where $\mathcal{O}_X$ is coherent, to say that a complex F is pseudo-coherent simply means that F has locally bounded-above cohomology and that all the $H^i(F)$ are coherent.

If $\mathcal{O}_X$ is a sheaf of regular local rings, every coherent $\mathcal{O}_X$-module F admits locally a finite resolution to the left by finite-type free modules, that is, there exists locally an exact sequence

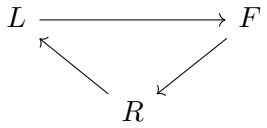
$$0 \longrightarrow L_n \longrightarrow \cdots \longrightarrow L_0 \longrightarrow F \longrightarrow 0,$$

where the L_i are free of finite type. It is therefore natural, when $\mathcal{O}_X$ is an arbitrary sheaf of local rings, to study the modules which have the preceding property. Such modules are called *perfect*. More generally, a complex F of $\mathcal{O}_X$-modules is said to be *perfect* if there exists locally a quasi-isomorphism $L \to F$, where L is a bounded complex with components free of finite type. It is shown in Exposé I, §3, that the full subcategory $\mathrm{D}(X)_{\mathrm{parf}}$ of $\mathrm{D}(X)$ formed by perfect

complexes is, like $\mathrm{D}(X)_{\mathrm{coh}}$, a triangulated subcategory, stable under inverse image and derived tensor product. One obviously has

$$\mathrm{D}(X)_{\mathrm{parf}} \subset \mathrm{D}(X)_{\mathrm{coh}},$$

but the inclusion is strict in general. Pseudo-coherence can be redefined "by passage to the limit" from perfection: a complex F is pseudo-coherent if and only if, for every $n \in \mathbb{Z}$, F can be locally approximated to order n by a perfect complex, meaning that there exists locally a distinguished triangle



with L perfect and R acyclic in degrees $> n$. Conversely, perfection is recovered from pseudo-coherence by means of an additional regularity condition: a complex is perfect if and only if it is pseudo-coherent and locally of finite Tor-dimension (Exposé I, §5). Thus one recovers the fact that, if the local rings are regular, every coherent sheaf is perfect, and more generally every pseudo-coherent complex with locally bounded cohomology is perfect.

Pseudo-coherence and perfection are the two fundamental finiteness notions with which we shall work in this Seminar. Sections 1 to 5 of Exposé I are devoted to their definition and to establishing their elementary stability properties. For this purpose, only two or three local properties of the category of finite-type free modules, relative to the category of all modules, are used. It is therefore convenient and useful, notably in Exposé II, to axiomatize the situation by introducing a notion of pseudo-coherence (respectively of perfection) in a category fibered over a site, relative to a fibered subcategory satisfying suitable conditions.

Sections 6 to 8 of Exposé I generalize to perfect complexes a certain number of notions well known for finite-type locally free sheaves: rank, duality, and the trace of an endomorphism.

In Exposé II, one examines the problem of the existence of "global resolutions": under what conditions, on a ringed topos $(X, \mathcal{O}_X)$, is a pseudo-coherent (respectively perfect) complex globally isomorphic in $\mathrm{D}(X)$ to a complex of locally free modules of finite type? The importance of this question lies essentially in the fact that at present one does not know how to generalize to perfect complexes certain usual constructions on locally free modules, such as exterior and symmetric powers or Chern classes. That is why it is useful to have workable sufficient criteria for the existence of global resolutions, which reduce certain questions about pseudo-coherent (respectively perfect) complexes to analogous questions about locally free sheaves of finite type. Such criteria are given in Exposé II.

In particular, one shows that global resolutions exist in the following cases: X is the Zariski topos of an affine scheme, or more generally of a quasi-compact scheme possessing an ample invertible sheaf, or even an ample family of invertible sheaves in the sense of Kleiman, for example a regular scheme; or again X is the topos of sheaves of sets on a compact topological space and $\mathcal{O}_X$ is the sheaf of continuous functions with complex values. By way of illustration, and to show the flexibility of the notions introduced, the appendix gives a "purely sheaf-theoretic" definition of the index of a family of elliptic operators.

Exposé III studies the stability of finiteness conditions under derived direct image. To obtain reasonable statements, one must relativize the notions of pseudo-coherence and perfection. We place ourselves here in the framework of ordinary schemes, which is sufficient for the Seminar, but there is no doubt that one will sooner or later need to develop an analogous theory for relative analytic schemes or spaces. Let $p : X \to S$ be an S-scheme locally of finite type, and let F be a complex of $\mathcal{O}_X$-modules. One says that F is pseudo-coherent (respectively perfect) relative to p if one can locally extend X, by a closed immersion, into a smooth S-scheme X',

so that F, extended by zero to X', is pseudo-coherent (respectively perfect). The notion of pseudo-coherence relative to p is especially interesting when S is not locally noetherian; in the opposite case it coincides with the ordinary notion of pseudo-coherence. Moreover, as expected, to say that F is perfect relative to p is equivalent to saying that F is pseudo-coherent relative to p and locally of finite Tor-dimension relative to p (i.e. relative to the sheaf of rings $p^{-1}(\mathcal{O}_S)$).

The central theorem of Exposé III is the following finiteness theorem, stated below in a slightly more precise form: if $f : X \to Y$ is a proper morphism of S-schemes locally of finite type, the functor Rf_* transforms complexes pseudo-coherent relative to S into complexes pseudo-coherent relative to S. This theorem is in fact a conjecture, but it is nevertheless proved in the two particular cases S locally noetherian and f projective. It seems likely, unfortunately, that the extension to the general case is of the same order of difficulty as the analogous theorem in analytic geometry, Grauert's theorem. Combining the finiteness theorem with an essentially trivial formula called the projection formula, one obtains workable criteria for the stability of relative perfection under direct image. As a corollary one recovers Grauert's continuity and semicontinuity theorems (EGA III 7.6).

Exposé IV translates the results of Exposés I to III into the language of "Grothendieck groups." On a ringed topos $(X, \mathcal{O}_X)$, write $K^*(X)$ (respectively $K_\bullet(X)$) for the Grothendieck group of the category of perfect complexes and complexes of finite Tor-dimension (respectively pseudo-coherent complexes with bounded homology). The group $K^*(X)$ is a ring, and $K_\bullet(X)$ is a module over $K^*(X)$. The functor K^* is contravariant, as suggested above, while $K_\bullet$ is covariant for proper pseudo-coherent morphisms of schemes, or of analytic spaces, subject to the availability of the finiteness theorem. There are also unusual variants: covariance of K^*, contravariance of $K_\bullet$, for morphisms satisfying suitable regularity hypotheses. Finally, the globalization criteria of Exposé II make it possible to link these groups with the "Grothendieck groups" defined naïvely from coherent sheaves or finite-type locally free sheaves.

1. Preliminary definitions

1.1. Fibered categories with additive fibers (respectively abelian, respectively triangulated fibers)

1.1.1. Let S be a category, and let $\mathcal{C}$ be an S-category fibered in categories with additive (respectively triangulated) fibers (SGA 1 VI 6.1). We shall say that $\mathcal{C}$ is an *additive* (respectively *triangulated*) S-category, or that $\mathcal{C}$ is additive (respectively triangulated) over S, if, for every arrow $f : X \to Y$ of S, the inverse-image functor

$$f^* : \mathcal{C}_Y \longrightarrow \mathcal{C}_X$$

(determined up to unique isomorphism) is additive (respectively exact). We shall say that $\mathcal{C}$ is an *abelian* S-category if $\mathcal{C}$ is an additive S-category with abelian fibers, and that $\mathcal{C}$ is a *flat abelian* S-category if, moreover, the inverse-image functors are exact.

1.1.2. Let $\mathcal{C}$ be a triangulated S-category. One defines, for example with the aid of a cleavage of $\mathcal{C}$ (SGA 1 VI 7.1), a fibered S-category $\mathrm{Tr}(\mathcal{C})$ whose fiber over each $X \in \mathrm{ob}(S)$ is the category $\mathrm{Tr}(\mathcal{C}_X)$ of distinguished triangles of $\mathcal{C}_X$.

1.1.3. Let $\mathcal{C}$ and $\mathcal{C}'$ be additive (respectively triangulated) S-categories, and let $F : \mathcal{C} \to \mathcal{C}'$ be a functor. We say that F is an additive (respectively exact) S-functor if F is a Cartesian S-functor that is additive (respectively exact) on each fiber.

1.1.3 (continued). If $\mathcal{C}$ and $\mathcal{C}'$ are triangulated S-categories and if F is an exact S-functor,

then F defines a Cartesian S-functor

$$\mathrm{Tr}(\mathcal{C}) \longrightarrow \mathrm{Tr}(\mathcal{C}').$$

1.1.4. Let $\mathcal{C}$ be a triangulated S-category, and let $\mathcal{C}'$ be a full fibered sub-S-category of $\mathcal{C}$. We say that $\mathcal{C}'$ is a *triangulated sub-S-category* of $\mathcal{C}$ if, for every $X \in \mathrm{ob}\, S$, $\mathcal{C}'_X$ is a triangulated subcategory of $\mathcal{C}_X$ [V], Chap. I, §1, 2.3.

1.1.5. Let $\mathcal{C}$ be an additive S-category. One defines (SGA 4 XVII 2.2, 2.4) an additive (respectively triangulated) S-category

$$\mathrm{C}(\mathcal{C}) \qquad \text{respectively} \qquad \mathrm{K}(\mathcal{C}),$$

whose fiber over $X \in \mathrm{ob}\, S$ is the category $\mathrm{C}(\mathcal{C}_X)$ of complexes with differential of degree $+1$ (respectively the category $\mathrm{K}(\mathcal{C}_X)$ of complexes of $\mathcal{C}_X$ "up to homotopy"). If $\mathcal{C}$ is a flat abelian S-category, one defines, loc. cit., a triangulated S-category $\mathrm{D}(\mathcal{C})$, whose fiber over $X \in \mathrm{ob}\, S$ is the derived category $\mathrm{D}(\mathcal{C}_X)$; if $f : X \to Y$ is an arrow of S, we shall write

$$f^* : \mathrm{D}(\mathcal{C}_Y) \longrightarrow \mathrm{D}(\mathcal{C}_X)$$

for the inverse-image functor, obtained from

$$f^* : \mathrm{K}(\mathcal{C}_Y) \longrightarrow \mathrm{K}(\mathcal{C}_X)$$

by passage to the quotient. One defines full triangulated sub-S-categories

$$\mathrm{K}^*(\mathcal{C}) \qquad \text{respectively} \qquad \mathrm{D}^*(\mathcal{C}) \quad (* = +, -, b)$$

by the usual degree conditions.

1.2. Terminology

Let S be a site, let $\mathcal{C}$ be a flat abelian S-category (1.1), and let $\mathcal{C}_0$ be a strictly full fibered sub-S-category.

Let $F \in \mathrm{ob}\, \mathcal{C}_X$, for $X \in \mathrm{ob}\, S$. The set of arrows $f : U \to X$ in S/X such that there exists an epimorphism

$$E \longrightarrow f^*F, \qquad E \in \mathrm{ob}\, \mathcal{C}_{0,U},$$

is a sieve on X. If this sieve is covering, we shall say that F is of $\mathcal{C}_0$-*finite type* (or simply of finite type when no confusion is to be feared).

We shall say that $\mathcal{C}_0$ is *locally stable under kernels of epimorphisms* if the following condition is satisfied: for every $X \in \mathrm{ob}\, S$ and every epimorphism

$$u : E \longrightarrow F$$

of $\mathcal{C}_X$, with $E, F \in \mathrm{ob}\, \mathcal{C}_{0,X}$, the kernel of u is locally in $\mathcal{C}_0$; in other words the set of $f : U \to X$ in S/X such that

$$f^* \mathrm{Ker}(u) \in \mathrm{ob}\, \mathcal{C}_{0,U}$$

is a refinement of X.

By the standard process of decomposing a long exact sequence into short exact sequences, one sees that the preceding condition is equivalent to the following apparently stronger one: for every $X \in \mathrm{ob}\, S$ and every exact sequence in $\mathcal{C}_X$

$$0 \longrightarrow E^0 \longrightarrow E^1 \longrightarrow \cdots \longrightarrow E^n \longrightarrow 0 \qquad (*)$$

with $E^i \in \mathrm{ob}\,\mathcal{C}_{0,X}$ for $1 \leq i \leq n$, the object E^0 is locally in $\mathcal{C}_0$.

We shall say that $\mathcal{C}_0$ is *locally quasi-stable under kernels of epimorphisms* if, for every exact sequence such as $(*)$, E^0 is of $\mathcal{C}_0$-finite type.

On the other hand, we shall say that $\mathcal{C}_0$ is *locally liftable in* $\mathcal{C}$ if, for every $X \in \mathrm{ob}\,S$, every epimorphism

$$u : E \longrightarrow F$$

of $\mathcal{C}_X$ with $F \in \mathrm{ob}\,\mathcal{C}_{0,X}$ locally admits a section. Equivalently, for $\mathcal{C}_0$ to be locally liftable in $\mathcal{C}$, it is necessary and sufficient that, for every diagram of $\mathcal{C}_X$, $X \in \mathrm{ob}\,S$,

$$\begin{array}{ccc} & & H \\ & & \downarrow \\ E & \xrightarrow[u]{} & F \end{array}$$

where u is an epimorphism and $H \in \mathrm{ob}\,\mathcal{C}_0$, the set of U over X for which there exists a commutative diagram

$$\begin{array}{ccc} & \nearrow & H_U \\ & & \downarrow \\ E_U & \xrightarrow[u_U]{} & F_U \end{array}$$

is a refinement of X.

We shall say that $\mathcal{C}_0$ is *locally quasi-liftable in* $\mathcal{C}$ if the following weaker condition is satisfied: for every $X \in \mathrm{ob}\,S$, and every epimorphism

$$u : E \longrightarrow F$$

of $\mathcal{C}_X$, with $F \in \mathrm{ob}\,\mathcal{C}_{0,X}$, the set of arrows $f : U \to X$ of S/X for which there exists

$$v : F' \longrightarrow f^*E, \qquad F' \in \mathrm{ob}\,\mathcal{C}_{0,U},$$

such that $f^*(u)v$ is an epimorphism, is a refinement of X. This condition is equivalent to the following: for every diagram in $\mathcal{C}_X$

$$\begin{array}{ccc} & & H \\ & & \downarrow \\ E & \xrightarrow[u]{} & F, \end{array}$$

where u is an epimorphism and $H \in \mathrm{ob}\,\mathcal{C}_0$, the set of U over X such that there exists a commutative diagram

$$\begin{array}{ccc} G & \xrightarrow{v} & H_U \\ \downarrow & & \downarrow \\ E_U & \xrightarrow[u_U]{} & F_U \end{array}$$

with $G \in \mathrm{ob}\,\mathcal{C}_0$ and v an epimorphism, is a refinement of X.

If S is a chaotic site, for example the punctual site (one object, one morphism), we shall omit the adverb "locally" in the preceding definitions.

1.3. Examples

a) Let S be the punctual site, let A be a ring, and let $\mathcal{C}$ be the category of left A-modules. The full subcategory $\mathcal{C}_0$ of $\mathcal{C}$ formed by the projective A-modules of finite type is stable under kernels

of epimorphisms and is liftable in $\mathcal{C}$; an A-module is of $\mathcal{C}_0$-finite type if and only if it is of finite type in the ordinary sense. The full subcategory $\mathcal{C}_1$ of $\mathcal{C}$ formed by the A-modules of finite type is quasi-liftable in $\mathcal{C}$, but is not liftable in general; if A is noetherian, $\mathcal{C}_1$ is stable under kernels of epimorphisms. The full subcategory $\mathcal{C}'_0$ of $\mathcal{C}$ formed by the free A-modules of finite type is liftable in $\mathcal{C}$ and quasi-stable, though not stable in general, under kernels of epimorphisms.

b) Let $(S, \mathcal{O}_S)$ be a space ringed by local rings, let S be the site of open subsets of S, and let $\mathcal{C}$ be the fibered S-category, even split (SGA 1 VI 9), defined by the functor

$$U \longmapsto \{\text{category of left } \mathcal{O}_U\text{-modules}\}.$$

Then $\mathcal{C}$ is a flat abelian S-category (1.1). Let $\mathcal{C}_0$ be the strictly full additive sub-S-category of $\mathcal{C}$ defined by

$$U \longmapsto \{\text{category of finite-type free } \mathcal{O}_U\text{-modules}\}.$$

An $\mathcal{O}_S$-module M is locally of $\mathcal{C}_0$-finite type if and only if M is of finite type in the ordinary sense (EGA 0_{I}, 5.2). From EGA 0_{I}, 5.2.7 and 5.4.9, it follows that $\mathcal{C}_0$ is locally stable under kernels of epimorphisms and locally liftable in $\mathcal{C}$.

c) Let G be a group, let S be the topos of G-sets (SGA 4 V 3.11), and let k be a field, regarded as the constant ring on S. Let $\mathcal{C}$ be the split S-category defined by

$$U \longmapsto \{\text{category of left } k_U\text{-modules}\};$$

then $\mathcal{C}$ is a flat abelian S-category. Let $\mathcal{C}_0$ be the strictly full additive sub-S-category of $\mathcal{C}$ defined by

$$U \longmapsto \{\text{category of finite-type free } k_U\text{-modules}\}.$$

Since localization in S is equivalent to forgetting the operations of G, it is clear that a G-k-module M is locally of $\mathcal{C}_0$-finite type if and only if M is finite-dimensional as a vector space over k, and that $\mathcal{C}_0$ is locally stable under kernels of epimorphisms and locally liftable in $\mathcal{C}$.

The reader is left to look at the "Galois" variant of c), where G is a profinite group and S is the topos of sets on which G operates continuously.

In fact, examples b) and c) are particular cases of the following example.

d) Let $(S, \mathcal{O}_S)$ be a ringed topos (cf. SGA 4 IV 2.10), and let $\mathcal{C}$ be the split S-category defined by

$$U \longmapsto \{\text{category of left } \mathcal{O}_U\text{-modules}\};$$

then $\mathcal{C}$ is a flat abelian S-category. Let $\mathcal{C}_0$ be the strictly full additive sub-S-category of $\mathcal{C}$ defined by

$$U \longmapsto \{\text{category of finite-type free } \mathcal{O}_U\text{-modules}\}.$$

An $\mathcal{O}_S$-module locally of $\mathcal{C}_0$-finite type will simply be called *of finite type*. The category $\mathcal{C}_0$ is locally quasi-stable under kernels of epimorphisms and locally liftable in $\mathcal{C}$, as follows from:

Lemma 1.3.1. Let P be an $\mathcal{O}_S$-module. The following conditions are equivalent:

(i) P is of finite type and the functor $\mathrm{Hom}(P, \cdot)$ is exact;

(ii) P is of finite type and every epimorphism $M \to P$ locally admits a section;

(iii) P is locally a direct factor of a free module of finite type.

The proof is immediate and is left as an exercise to the reader.

1.4. An "extension" lemma (cf. EGA 0_{III}, 11.9.1)

Proposition 1.4.1. Let S be a site, let $\mathcal{C}$ be a flat abelian S-category (1.1), and let $\mathcal{C}_0$ be a strictly full additive sub-S-category of $\mathcal{C}$. Assume that $\mathcal{C}_0$ is locally quasi-liftable in $\mathcal{C}$ (1.2). Let $S \in \mathrm{ob}\, S$, let

$$u : E \longrightarrow F$$

be a morphism, of degree 0, of complexes of $\mathcal{C}_S$ (differentials of degree +1), let G be the cone of u (cf. [V], Chap. I, §1, 2.1), let $n \in \mathbb{Z}$, and assume that $\mathrm{H}^n(G)$ is of $\mathcal{C}_0$-finite type (1.2). Then the set of $X \in \mathrm{ob}(S/S)$ satisfying property (P) below is a refinement of S.

(P): there exist an object $M \in \mathcal{C}_{0,X}$ and arrows of $\mathcal{C}_X$

$$r : M \longrightarrow Z^{n+1}(E_X) = \mathrm{Ker}\left(E_X^{n+1} \xrightarrow{d^{n+1}} E_X^{n+2}\right), \qquad s : M \longrightarrow F_X^n$$

such that the following diagram of $\mathcal{C}_X$

$$\begin{array}{ccccccc}
\cdots \to E_X^{n-1} & \xrightarrow{\binom{d_E^{n-1}}{0}} & E_X^n \oplus M & \xrightarrow{(d_E^n, r)} & E_X^{n+1} \to \cdots \\
\Big\downarrow{\scriptstyle u_X^{n-1}} & & \Big\downarrow{\scriptstyle (u_X^n, s)} & & \Big\downarrow{\scriptstyle u_X^{n+1}} \\
\cdots \to F_X^{n-1} & \xrightarrow[d_F^{n-1}]{} & F_X^n & \xrightarrow[d_F^n]{} & F_X^{n+1} \to \cdots
\end{array}$$

is a morphism of complexes $u' : E' \to F_X$, that is,

$$d_F^n s = u_X^{n+1} r,$$

and such that

(i) $\mathrm{H}^{n+1}(u')$ is a monomorphism, with

$$\Im \mathrm{H}^{n+1}(u') = \Im \mathrm{H}^{n+1}(u_X);$$

(ii) $\mathrm{H}^n(u')$ is an epimorphism.

In pictorial terms, one may say that, after modifying E and u locally in degree n only by adding, in degree n, an object of $\mathcal{C}_0$, one can locally make $\mathrm{H}^{n+1}(u)$ injective, without changing its image, and $\mathrm{H}^n(u)$ surjective.

Proof. The procedure is as follows: first one shows that r and s may be chosen locally so as to make $\mathrm{H}^{n+1}(u)$ injective; one verifies that the finiteness hypothesis on $\mathrm{H}^n(G)$ is preserved; a new local correction in degree n then makes it possible to obtain $\mathrm{H}^n(u)$ surjective.

The exact cohomology sequence

$$\cdots \longrightarrow \mathrm{H}^n(G) \longrightarrow \mathrm{H}^{n+1}(E) \longrightarrow \mathrm{H}^{n+1}(F) \longrightarrow \cdots$$

shows that the kernel of $\mathrm{H}^{n+1}(u)$ is of $\mathcal{C}_0$-finite type. In other words, the set of X over S for which there is an exact sequence

$$M \longrightarrow \mathrm{H}^{n+1}(E_X) \xrightarrow{\mathrm{H}^{n+1}(u)} \mathrm{H}^{n+1}(F_X), \qquad M \in \mathrm{ob}\, \mathcal{C}_{0,X},$$

is a refinement of S. Since $\mathcal{C}_0$ is locally quasi-liftable in $\mathcal{C}$, one may moreover impose that the arrow

$$M \longrightarrow \mathrm{H}^{n+1}(E_X)$$

factor through $Z^{n+1}(E_X)$:

$$M \xrightarrow{r} Z^{n+1}(E_X) \longrightarrow \mathrm{H}^{n+1}(E_X).$$

The composite

$$M \xrightarrow{u_X^{n+1} r} Z^{n+1}(F_X) \longrightarrow \mathrm{H}^{n+1}(F_X)$$

is zero by construction, so $u_X^{n+1} r$ factors through

$$B^{n+1}(F_X) = \mathfrak{F}\left(F_X^n \xrightarrow{d_F^n} F_X^{n+1}\right).$$

Applying quasi-liftability once more, one may impose that $u_X^{n+1} r$ factor through F_X^n:

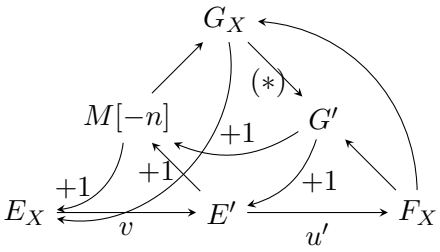
$$M \xrightarrow{s} F_X^n \longrightarrow B^{n+1}(F_X) \longrightarrow Z^{n+1}(F_X).$$

Then u', defined as in (1.4.1), is plainly a morphism of complexes satisfying (i).

Let G' be the cone of $u' : E' \to F_X$. We show that $\mathrm{H}^n(G')$ is of $\mathcal{C}_0$-finite type. By construction there is an exact sequence

$$0 \longrightarrow E_X \xrightarrow{v} E' \longrightarrow M[-n] \longrightarrow 0,$$

with $u'v = u_X$. To compare G_X and G', one may, for instance, form the octahedron in $\mathrm{K}(\mathcal{C}_X)$:



The exact cohomology sequence of the distinguished triangle marked by the octahedron shows that

$$\mathrm{H}^n(G_X) \longrightarrow \mathrm{H}^n(G')$$

is an epimorphism; hence $\mathrm{H}^n(G')$ is indeed of $\mathcal{C}_0$-finite type.

The preceding correction therefore reduces us to the case where $\mathrm{H}^{n+1}(u)$ is a monomorphism. We suppose this from now on. The exact cohomology sequence of $E \to F \to G$ then gives an exact sequence

$$\mathrm{H}^n(E) \xrightarrow{\mathrm{H}^n(u)} \mathrm{H}^n(F) \longrightarrow \mathrm{H}^n(G) \longrightarrow 0.$$

Since $\mathrm{H}^n(G)$ is of $\mathcal{C}_0$-finite type, the set of X over S for which there exists an epimorphism

$$M \longrightarrow \mathrm{H}^n(G_X), \qquad M \in \mathrm{ob}\,\mathcal{C}_{0,X},$$

is, by definition, a refinement of S. Using the quasi-liftability of $\mathcal{C}_0$ in $\mathcal{C}$, one may impose that this epimorphism factor through $Z^n(F_X)$:

$$M \xrightarrow{s} Z^n(F_X) \longrightarrow \mathrm{H}^n(F_X) \longrightarrow \mathrm{H}^n(G_X).$$

It is clear that u', defined as in (1.4.1) with $r = 0$, is a morphism of complexes and that

$$\mathrm{H}^n(u') : \mathrm{H}^n(E_X) \oplus M \longrightarrow \mathrm{H}^n(F_X)$$

is an epimorphism. This completes the proof of (1.4.1).

Lemma 1.4.2. Let $\mathcal{C}$ be an abelian category, let $u : E \to F$ be a morphism of complexes of $\mathcal{C}$ (respectively an arrow of $\mathrm{D}(\mathcal{C})$), and let G be the cone of u. For a given $n \in \mathbb{Z}$, the following conditions are equivalent:

(i) $\mathrm{H}^i(G) = 0$ for $i \geq n$;

(ii) $\mathrm{H}^i(u)$ is an isomorphism for $i > n$ and an epimorphism for $i = n$.

The proof is immediate from the exact cohomology sequence.

Definition 1.4.3. We shall say that u is an *n-quasi-isomorphism* (respectively an *n-isomorphism*) if u satisfies the equivalent conditions of (1.4.2).

That being so, one deduces at once from (1.4.1) the following:

Corollary 1.4.4. Let $S, S, \mathcal{C}, \mathcal{C}_0$ be as in (1.4.1). Let $u : E \to F$ be an $(n+1)$-quasi-isomorphism of complexes of $\mathcal{C}_S$, with $n \in \mathbb{Z}$ fixed, such that $\mathrm{H}^n(G)$ is of $\mathcal{C}_0$-finite type. Then the set of X over S for which there exist (M, r, s) as in (1.4.1) such that u' is an n-quasi-isomorphism is a refinement of S.

In pictorial terms, one may, using the finiteness condition on $\mathrm{H}^n(G)$, locally "gain one notch," that is, locally modify u in degree n by adding to E^n an object of $\mathcal{C}_0$ in such a way as to make u an n-quasi-isomorphism.

Corollary 1.4.5. Let $\mathcal{C}$ be an abelian category, let $n \in \mathbb{Z}$, and let $u : E \to F$ be an n-quasi-isomorphism of complexes of $\mathcal{C}$. There exists a commutative diagram in $\mathrm{C}(\mathcal{C})$

$$\begin{array}{ccc} E & \xrightarrow{v} & E' \\ {\scriptstyle u}\downarrow & \swarrow_{u'} & \\ F & & \end{array}$$

where u' is a quasi-isomorphism and v is a monomorphism inducing the identity in degrees $\geq n$, that is,

$$E'^i = E^i, \qquad v^i = \mathrm{Id}(E^i) \qquad \text{for } i \geq n.$$

Proof. Applying (1.4.4) in the case where S is the punctual site and $\mathcal{C}_0 = \mathcal{C}$, one obtains a commutative triangle in $\mathrm{C}(\mathcal{C})$

$$\begin{array}{ccc} E & \xrightarrow{v_{n-1}} & E'_{n-1} \\ {\scriptstyle u}\downarrow & \swarrow_{u'_{n-1}} & \\ F & & \end{array}$$

where u'_{n-1} is an $(n-1)$-quasi-isomorphism and v_{n-1} is a monomorphism inducing the identity in degrees $\geq n$. Iterating the process, one finds, for $i \leq n-1$, a sequence of commutative triangles in $\mathrm{C}(\mathcal{C})$

$$\begin{array}{ccc} E'_i & \xrightarrow{v_{i-1}} & E'_{i-1} \\ {\scriptstyle u'_i}\downarrow & \swarrow_{u'_{i-1}} & \\ F & & \end{array}$$

where u'_i is an i-quasi-isomorphism and v_{i-1} is a monomorphism inducing the identity in degrees $\geq i$. The corollary follows by passing to the limit. More precisely, writing d'_i for the differential of E'_i, define E' by

$$E'^i = E^i, \quad d'^i = d^i \quad (i \geq n),$$

and

$$E'^i = (E'_i)^i, \quad d'^i = (d'_i)^i \quad (i < n),$$

and then define v and u' by

$$v^j = (v_i)^j, \qquad u'^j = (u'_i)^j \qquad (i \leq j).$$

One immediately verifies that E', v, and u', so defined, answer the question.

In abbreviated form: one can extend an n-quasi-isomorphism into a quasi-isomorphism "without changing anything given in degree $> n$."

2. Pseudo-coherent complexes

2.0. In this section, S denotes a site, S an object of S, $\mathcal{C}$ a flat abelian S-category (1.1), and $\mathcal{C}_0$ a strictly full additive sub-S-category of $\mathcal{C}$. We assume that $\mathcal{C}_0$ is locally quasi-stable under kernels of epimorphisms (1.2) and locally quasi-liftable in $\mathcal{C}$ (1.2).

Definition 2.1. Let $X \in \operatorname{ob} S$, let E be a complex of $\mathcal{C}_X$, and let $n \in \mathbb{Z}$. We shall say that E is *strictly $\mathcal{C}_0$-n-pseudo-coherent* (respectively $\mathcal{C}_0$-pseudo-coherent, respectively $\mathcal{C}_0$-perfect) if $E^i = 0$ for i sufficiently large and $E^i \in \operatorname{ob} \mathcal{C}_{0,S}$ for $i \geq n$ (respectively for every i, respectively for every i and $E^i = 0$ for almost all i).

When no confusion is to be feared, we shall sometimes say "strictly n-pseudo-coherent" (respectively, and so on) instead of "strictly $\mathcal{C}_0$-n-pseudo-coherent".

Lemma 2.1.1. Let $E \in \operatorname{ob} \mathrm{C}(\mathcal{C}_S)$ and $n \in \mathbb{Z}$. If E is strictly n-pseudo-coherent and if $\mathrm{H}^i(E) = 0$ for $i > n$, then $\mathrm{H}^n(E)$ is of finite type.

Proof. The sequence

$$0 \longrightarrow Z^n(E) \longrightarrow E^n \longrightarrow E^{n+1} \longrightarrow \cdots \longrightarrow 0$$

is exact, and $E^i \in \operatorname{ob} \mathcal{C}_0$ for $i \geq n$. Since $\mathcal{C}_0$ is locally quasi-stable under kernels of epimorphisms, it follows that $Z^n(E)$ is of finite type, hence so is $\mathrm{H}^n(E)$, which is a quotient of it.

Proposition 2.2. Let $F \in \operatorname{ob} \mathrm{D}(\mathcal{C}_S)$ and $n \in \mathbb{Z}$. Then:

a) If F is strictly n-pseudo-coherent (relative to $\mathcal{C}_0$) and if

$$u : E \longrightarrow F$$

is a quasi-isomorphism, then the set of X over S such that there exists a quasi-isomorphism

$$v : F' \longrightarrow E_X$$

with F' strictly n-pseudo-coherent is a refinement of S.

b) The following conditions are equivalent:

(i) the set of X over S such that there exists a quasi-isomorphism

$$u : E \longrightarrow F_X$$

of $\mathrm{C}(\mathcal{C}_X)$, with E strictly n-pseudo-coherent, is a refinement of S;

(i′) the same condition as (i), but with u an isomorphism of $\mathrm{D}(\mathcal{C}_X)$;

(ii) the set of X over S such that there exists an n-quasi-isomorphism

$$u : E \longrightarrow F_X$$

of $\mathrm{C}(\mathcal{C}_X)$, with E strictly perfect, is a refinement of S;

(ii′) the same condition as (ii), but with u an n-isomorphism of $\mathrm{D}(\mathcal{C}_X)$.

Proof. For a), there exists, for i sufficiently large, an i-quasi-isomorphism

$$v_i : F'_i \longrightarrow E$$

with F'_i strictly n-pseudo-coherent (take $F'_i = 0$). We show that, if $i > n$, there exists, after refining S, an $(i-1)$-quasi-isomorphism

$$v_{i-1} : F'_{i-1} \longrightarrow E$$

with F'_{i-1} strictly n-pseudo-coherent. By (1.4.4), it is enough to show that $\mathrm{H}^{i-1}(M')$, where M' is the cone of v_i, is of $\mathcal{C}_0$-finite type. Now if M'' denotes the cone of uv_i, the hypothesis that u is a quasi-isomorphism and (1.4.2) imply that

$$\mathrm{H}^j(M') \xrightarrow{\sim} \mathrm{H}^j(M'') \qquad \text{for all } j,$$

and

$$\mathrm{H}^j(M') = 0 \qquad \text{for } j \geq i.$$

The cone formula

$$M''^j = F_i'^{\,j+1} \oplus F^j$$

shows, on the other hand, that M'' is strictly $(i-1)$-pseudo-coherent. Hence, by (2.1.1),

$$\mathrm{H}^{i-1}(M'') = \mathrm{H}^{i-1}(M')$$

is of finite type, whence the assertion. It follows, by iteration and after refining S, that there is an n-quasi-isomorphism

$$v_n : F'_n \longrightarrow E$$

where F'_n is strictly n-pseudo-coherent. But, by (1.4.5), one can extend v_n into a quasi-isomorphism

$$v : F' \longrightarrow E$$

without changing anything in degrees $\geq n$; in particular F' is strictly n-pseudo-coherent. This proves a).

For b), the equivalence of (i) and (i′) follows at once from a) and from the definition of isomorphisms of $\mathrm{D}^-(\mathcal{C}_X)$. If $E \in \mathrm{ob}\,\mathrm{D}^-(\mathcal{C}_S)$ is strictly n-pseudo-coherent, there is an exact sequence

$$0 \longrightarrow E' \longrightarrow E \longrightarrow E'' \longrightarrow 0$$

where E' is strictly perfect and $E''^i = 0$ for $i \geq n$. Consequently $E' \to E$ is an n-quasi-isomorphism, which gives the implication (i) ⇒ (ii). The implication (ii) ⇒ (ii′) is trivial, so it remains to prove (ii′) ⇒ (i). Let

$$u : E \longrightarrow F$$

be an n-isomorphism of $\mathrm{D}^-(\mathcal{C}_S)$, with E strictly perfect. Then u is represented by a diagram in $\mathrm{C}^-(\mathcal{C}_S)$

$$\begin{array}{ccc} & E' & \\ {\scriptstyle s}\swarrow & & \searrow{\scriptstyle u'} \\ E & & F, \end{array}$$

where s is a quasi-isomorphism and u' an n-quasi-isomorphism. By a), after refining S, there exists a quasi-isomorphism

$$t : E'' \longrightarrow E',$$

with E'' strictly n-pseudo-coherent. Applying (1.4.5) to $u't : E'' \to F$, we extend it to a quasi-isomorphism

$$E''' \longrightarrow F$$

with E''' strictly n-pseudo-coherent. This proves (ii$'$) $\Rightarrow$ (i) and completes the proof of (2.2).

Definition 2.3. Under the hypotheses of (2.2), we shall say that $F \in \mathrm{ob}\,\mathrm{D}^-(\mathcal{C}_S)$ is n-$\mathcal{C}_0$-pseudo-coherent if F satisfies the equivalent conditions b) of (2.2). We shall say that F is $\mathcal{C}_0$-pseudo-coherent if F is n-$\mathcal{C}_0$-pseudo-coherent for every n.

When this cannot cause confusion, we shall sometimes allow ourselves to say n-pseudo-coherent, pseudo-coherent, instead of n-$\mathcal{C}_0$-pseudo-coherent, $\mathcal{C}_0$-pseudo-coherent.

Remark 2.3.1. Let $F \in \mathrm{ob}\,\mathrm{D}(\mathcal{C}_S)$ be a pseudo-coherent complex. The set of X over S such that there exists a quasi-isomorphism

$$E \longrightarrow F_X$$

with E strictly pseudo-coherent (2.1) is not in general a refinement of S. However, we shall see later (2.7 a) and Exposé II) important cases in which this is so.

The proof of (2.2 a) gives the following result.

Proposition 2.4. Let $n, i \in \mathbb{Z}$, and let

$$u : E \longrightarrow F$$

be an i-quasi-isomorphism of $\mathrm{C}(\mathcal{C}_S)$, with F n-pseudo-coherent and E strictly n-pseudo-coherent. Then, after refining S, there exists a commutative triangle in $\mathrm{C}(\mathcal{C}_S)$

$$\begin{array}{ccc} E & \xrightarrow{v} & E' \\ {\scriptstyle u}\downarrow & \swarrow{\scriptstyle u'} & \\ F & & \end{array}$$

where E' is strictly n-pseudo-coherent, u' is a quasi-isomorphism, and v is a monomorphism inducing the identity in degree $\geq i$.

Proposition 2.5. a) If $F \in \mathrm{ob}\,\mathrm{D}(\mathcal{C}_S)$ is n-pseudo-coherent (respectively pseudo-coherent), then $F[m]$ is $(n-m)$-pseudo-coherent (respectively pseudo-coherent).

b) Let

$$\begin{array}{ccc} E & \longrightarrow & F \\ & {\scriptstyle +1}\nwarrow \quad \swarrow & \\ & G & \end{array} \qquad (*)$$

be a distinguished triangle of $\mathrm{D}(\mathcal{C}_S)$. If E and G are n-pseudo-coherent (respectively pseudo-coherent), then F is n-pseudo-coherent (respectively pseudo-coherent).

Proof. a) is trivial from the definitions.

b) It is enough, of course, to prove the non-parenthesized assertion. The triangle $(*)$ can also be written

$$\begin{array}{ccc} G[-1] & \longrightarrow & E \\ & {\scriptstyle +1}\nwarrow \quad \swarrow & \\ & F & \end{array}$$

By a), $G[-1]$ is $(n+1)$-pseudo-coherent. Thus we are reduced to proving that, if E is $(n+1)$-pseudo-coherent and F is n-pseudo-coherent, then G is n-pseudo-coherent. After localizing, we

may assume E (respectively F) strictly $(n+1)$-pseudo-coherent (respectively n-pseudo-coherent). The arrow

$$E \xrightarrow{u} F$$

of $\mathrm{D}^-(\mathcal{C}_S)$ is represented by a pair of arrows of $\mathrm{C}^-(\mathcal{C}_S)$

$$\begin{array}{ccc} & E' & \\ {\scriptstyle s}\swarrow & & \searrow{\scriptstyle u'} \\ E & & F, \end{array}$$

where s is a quasi-isomorphism. By (2.2 a)), after localizing, there exists a quasi-isomorphism

$$t : E'' \longrightarrow E',$$

where E'' is strictly $(n+1)$-pseudo-coherent. We are therefore reduced to the case where u is defined by a true arrow of $\mathrm{C}^-(\mathcal{C}_S)$. The assertion then follows from the definitions and from the formula

$$C(u)^i = E^{i+1} \oplus F^i,$$

where $C(u)$ denotes the cone of u.

Scholium 2.6. By rotation of triangles, one sees that pseudo-coherence properties for two of the objects of the triangle $(*)$ imply another such property for the third. The various cases may be summarized in the table below; the lower-case letters denote degrees of pseudo-coherence, and in each row the conclusion is underlined:

$$\begin{array}{ccc} E & F & G \\ n+1 & n & \underline{n} \\ n & \underline{n} & n \\ \underline{n} & n & n-1. \end{array}$$

We shall write

$$\mathrm{D}(\mathcal{C})_{\mathcal{C}_0\text{-}n\mathrm{coh}} \quad \text{respectively} \quad \mathrm{D}(\mathcal{C})_{\mathcal{C}_0\text{-coh}}$$

for the strictly full fibered subcategory of $\mathrm{D}(\mathcal{C})$ whose fiber over each $X \in \mathrm{ob}\, S$ is formed by the objects of $\mathrm{D}(\mathcal{C}_X)$ that are n-pseudo-coherent (respectively pseudo-coherent) relative to $\mathcal{C}_0$. By (2.5), the category

$$\mathrm{D}(\mathcal{C})_{\mathcal{C}_0\text{-coh}}$$

is a triangulated sub-S-category of $\mathrm{D}(\mathcal{C})$ (1.1).

Proposition 2.7. Suppose that S is the punctual site, so that

$$\mathcal{C} = \mathcal{C}_S, \qquad \mathcal{C}_0 = \mathcal{C}_{0,S}.$$

Then:

a) If $F \in \mathrm{ob}\, \mathrm{D}(\mathcal{C})$ is pseudo-coherent, there exists a quasi-isomorphism

$$E \longrightarrow F$$

with E strictly pseudo-coherent (2.1).

b) Let $\mathrm{K}^{-,\mathrm{ac}}(\mathcal{C}_0)$ denote the full triangulated subcategory of $\mathrm{K}^-(\mathcal{C}_0)$ formed by acyclic complexes. The canonical functor

$$\mathrm{K}^-(\mathcal{C}_0)/\mathrm{K}^{-,\mathrm{ac}}(\mathcal{C}_0) \longrightarrow \mathrm{D}(\mathcal{C})$$

is fully faithful and has essential image $\mathrm{D}(\mathcal{C})_{\mathcal{C}_0\text{-coh}}$.

Proof. a) Let $F \in \mathrm{ob}\,\mathrm{D}(\mathcal{C})_{\mathcal{C}_0\text{-coh}}$, and suppose constructed an i-quasi-isomorphism

$$u_i : E_i \longrightarrow F$$

of $\mathrm{C}(\mathcal{C})$, with E_i strictly pseudo-coherent; this is possible for i sufficiently large, taking $E_i = 0$. Let G_i be the cone of u_i. It follows from (1.4.2) and (2.1.1) that $\mathrm{H}^{i-1}(G_i)$ is of $\mathcal{C}_0$-finite type. Hence, by (1.4.4), there exists a commutative triangle in $\mathrm{C}(\mathcal{C})$

$$\begin{array}{ccc} E_i & \xrightarrow{v_{i-1}} & E_{i-1} \\ {\scriptstyle u_i}\downarrow & \swarrow_{u_{i-1}} & \\ F & & \end{array}$$

where E_{i-1} is strictly pseudo-coherent, u_{i-1} an $(i-1)$-quasi-isomorphism, and v_{i-1} a monomorphism inducing the identity in degrees $\geq i$. Passing to the limit (cf. the proof of (1.4.5)) gives a quasi-isomorphism

$$u : E \longrightarrow F$$

with E strictly pseudo-coherent.

b) Apply the criterion of [*V*], Chap. I, §2, 4.2 b)(i), together with a).

We note that the proof of a) gives the following more precise result, which generalizes (1.4.5).

Proposition 2.7.1. Under the hypotheses of (2.7), let $u : E \to F$ be an n-quasi-isomorphism of $\mathrm{C}(\mathcal{C})$, with F pseudo-coherent and E strictly pseudo-coherent. Then there exists a commutative triangle in $\mathrm{C}(\mathcal{C})$

$$\begin{array}{ccc} E & \xrightarrow{v} & E' \\ {\scriptstyle u}\downarrow & \swarrow_{u'} & \\ F & & \end{array}$$

where E' is strictly pseudo-coherent, u' is a quasi-isomorphism, and v is a monomorphism inducing the identity in degree $\geq n$.

Definition 2.8. Let $n \in \mathbb{N}$ and $F \in \mathrm{ob}\,\mathcal{C}_S$. We shall say that F is of n-$\mathcal{C}_0$-finite presentation if the set of X over S such that there exists an exact sequence

$$E^{-n} \longrightarrow \cdots \longrightarrow E^0 \longrightarrow F_X \longrightarrow 0, \qquad E^i \in \mathrm{ob}\,\mathcal{C}_{0,X} \quad (-n \leq i \leq 0),$$

is a refinement of S. We shall say that F is of ∞-$\mathcal{C}_0$-finite presentation if F is of n-$\mathcal{C}_0$-finite presentation for every $n \in \mathbb{N}$.

Of course, we shall sometimes simply say n-finite presentation when there is no possible ambiguity about $\mathcal{C}_0$. We shall say "finite presentation" for "1-finite presentation," and "finite type" for "0-finite presentation," the latter notion coinciding with the one already introduced in (1.2).

Proposition 2.9. Let $n \in \mathbb{N}$ and $F \in \mathrm{ob}\,\mathcal{C}_S$. The following conditions are equivalent:

(i) F is of n-finite presentation (respectively of ∞-finite presentation);

(ii) F is $(-n)$-pseudo-coherent (respectively pseudo-coherent).

In the case where S is the punctual site, F is pseudo-coherent if and only if there exists an exact sequence

$$\cdots \longrightarrow E^i \longrightarrow \cdots \longrightarrow E^0 \longrightarrow F \longrightarrow 0, \qquad E^i \in \mathrm{ob}\,\mathcal{C}_0 \quad \text{for all } i.$$

Proof. For the equivalence (i) $\Leftrightarrow$ (ii), it is plainly enough to treat the non-parenthesized case. The implication (i) $\Rightarrow$ (ii) is immediate from the definitions, and (ii) $\Rightarrow$ (i) follows at once from

(2.4): the arrow $0 \to F$ is a 1-quasi-isomorphism, and from this one deduces, after localizing, a quasi-isomorphism

$$E \longrightarrow F$$

with E strictly $(-n)$-pseudo-coherent and $E^i = 0$ for $i \geq 1$, that is, an n-finite presentation of F. The second assertion is proved in the same way, using (2.7.1).

Proposition 2.10. a) Let $m, n \in \mathbb{Z}$, with $n \leq m$. If $F \in \mathrm{ob}\,\mathrm{D}^-(\mathcal{C}_S)$ is n-pseudo-coherent and acyclic in degrees $\geq m$, then there exists locally a quasi-isomorphism

$$E \longrightarrow F$$

with E strictly n-pseudo-coherent and $E^i = 0$ for $i \geq m$. If S is punctual, and if F is pseudo-coherent and acyclic in degrees $\geq m$, there exists a quasi-isomorphism

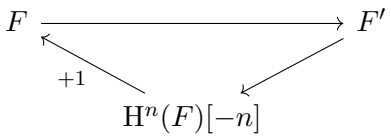
$$E \longrightarrow F$$

with E strictly pseudo-coherent and $E^i = 0$ for $i \geq m$.

b) Let $F \in \mathrm{ob}\,\mathrm{D}^-(\mathcal{C}_S)$ be acyclic in degrees $> n$. For F to be n-pseudo-coherent, it is necessary and sufficient that $\mathrm{H}^n(F)$ be of finite type.

Proof. a) Since F is acyclic in degrees $\geq m$, the arrow $0 \to F$ is an m-quasi-isomorphism. The assertion follows from (2.4) and (2.7.1).

b) There exists a distinguished triangle in $\mathrm{D}^-(\mathcal{C}_S)$:



(to see this, begin by truncating F, replacing F^n by $Z^n(F)$ and F^i by 0 for $i > n$). The exact cohomology sequence implies

$$\mathrm{H}^i(F') = 0 \quad \text{for } i \geq n-1,$$

so F' is $(n-1)$-pseudo-coherent. We conclude by (2.5) and (2.6).

Exposé I, continued: pseudo-coherent complexes and perfect complexes

Proposition 2.11. Let $n \in \mathbb{Z}$.

a) Let $F \in \mathrm{ob}\,\mathrm{C}^-(\mathcal{C}_S)$. If, for every $i \geq n$ (respectively for every i), F^i is of finite $(i-n)$-presentation (respectively of finite ∞-presentation), then F is n-pseudo-coherent (respectively pseudo-coherent).

b) Let $F \in \mathrm{ob}\,\mathrm{D}^-(\mathcal{C}_S)$. If, for every $i \geq n$ (respectively for every i), $\mathrm{H}^i(F)$ is of finite $(i-n)$-presentation (respectively of finite ∞-presentation), then F is pseudo-coherent.

Proof. It is enough to treat the non-parenthesized assertions.

a) We argue by induction on N such that $F^i \neq 0$ only for $i \leq n+N$. If $N = 0$, the assertion follows at once from (2.10 b). Suppose $N \geq 1$. We have an exact sequence

$$0 \longrightarrow F^{n+N}[-n-N] \longrightarrow F \longrightarrow F' \longrightarrow 0.$$

By the induction hypothesis, F' is n-pseudo-coherent; on the other hand $F^{n+N}[-n-N]$ is n-pseudo-coherent by hypothesis, using (2.9 and 2.5 a). Hence, by (2.5 b), F is n-pseudo-coherent.

b) We argue by induction on N such that $\mathrm{H}^i(F) = 0$ for $i > n+N$. If $N = 0$, the assertion follows from (2.10 b). Suppose $N \geq 1$. As in the proof of (2.10 b), we have a distinguished triangle in $\mathrm{D}^-(\mathcal{C}_S)$

$$F' \longrightarrow F \longrightarrow \mathrm{H}^{n+N}(F)[-n-N] \longrightarrow F'[1].$$

more plainly, with cone $\mathrm{H}^{n+N}(F)[-n-N]$. The exact cohomology sequence implies

$$\mathrm{H}^i(F') = 0 \quad \text{for } i > n+N-1,$$

that is, for $i > (n-1)+(N-1)$, and

$$\mathrm{H}^i(F') \xrightarrow{\sim} \mathrm{H}^{i+1}(F) \quad \text{for } i < n+N-1.$$

By the induction hypothesis, applied with $n-1$ in place of n, F' is therefore $(n-1)$-pseudo-coherent. On the other hand, $\mathrm{H}^{n+N}(F)[-n-N]$ is n-pseudo-coherent by (2.9 and 2.5 a). Hence, by (2.6), F is n-pseudo-coherent.

Remark 2.11.1. If F is pseudo-coherent, the F^i (respectively the $\mathrm{H}^i(F)$) are not in general pseudo-coherent, nor even of finite type. Nevertheless, in the following paragraph, in the excursions on the notions of coherence, we shall see important examples where pseudo-coherence of F implies that of the $\mathrm{H}^i(F)$.

Proposition 2.12. Let $F', F'' \in \mathrm{ob}\,\mathrm{D}^-(\mathcal{C}_S)$, and let $F = F' \oplus F''$. For F to be n-pseudo-coherent (respectively pseudo-coherent), it is necessary and sufficient that F' and F'' be n-pseudo-coherent (respectively pseudo-coherent).

Proof. It is enough to prove the non-parenthesized assertion. Sufficiency is obvious; let us prove necessity. By induction we may suppose that it has already been proved that F' and F'' are $(n+1)$-pseudo-coherent. After localizing, we may even suppose that F' and F'' are strictly $(n+1)$-pseudo-coherent and that $F = F' \oplus F''$ in $\mathrm{C}^-(\mathcal{C}_S)$. Let $F'_{>n}$ (respectively $F'_{\leq n}$) denote the complex obtained from F' by replacing F'^i by 0 for $i \leq n$ (respectively for $i > n$), and define $F''_{>n}$ and $F''_{\leq n}$ similarly. We have an exact sequence

$$0 \longrightarrow F'_{>n} \oplus F''_{>n} \longrightarrow F \longrightarrow F'_{\leq n} \oplus F''_{\leq n} \longrightarrow 0.$$

The complex $F'_{>n} \oplus F''_{>n}$ is strictly perfect; since F is n-pseudo-coherent, (2.6) implies that $F'_{\leq n} \oplus F''_{\leq n}$ is n-pseudo-coherent. This means, by (2.10 b), that

$$\mathrm{H}^n(F'_{\leq n} \oplus F''_{\leq n})$$

is of finite type. But

$$\mathrm{H}^n(F'_{\leq n} \oplus F''_{\leq n}) = \mathrm{H}^n(F'_{\leq n}) \oplus \mathrm{H}^n(F''_{\leq n}),$$

so $\mathrm{H}^n(F'_{\leq n})$ (respectively $\mathrm{H}^n(F''_{\leq n})$) is of finite type, and again by (2.10 b) $F'_{\leq n}$ (respectively $F''_{\leq n}$) is n-pseudo-coherent. Applying (2.5) to the exact sequence

$$0 \longrightarrow F'_{>n} \longrightarrow F' \longrightarrow F'_{\leq n} \longrightarrow 0$$

(and similarly for F''), we deduce that F' and F'' are n-pseudo-coherent.

Proposition 2.13. Let $(S', \mathcal{C}', \mathcal{C}'_0)$ be a triple satisfying the same hypotheses (2.0) as $(S, \mathcal{C}, \mathcal{C}_0)$. Let $f : S' \to S$ be a morphism of sites, corresponding to an underlying functor $f^{-1} : S \to S'$, and let

$$u : \mathrm{D}^*(\mathcal{C}) \longrightarrow \mathrm{D}^*(\mathcal{C}') \qquad (* = +, -, b)$$

be a Cartesian functor above f, exact on each fiber. Suppose that there exist $a, b \in \mathbb{Z}$ such that, for every $S \in \mathrm{ob}\,S$, the following conditions hold:

(i) if $E \in \operatorname{ob} \mathcal{C}_{0,S}$, then $u(E)$ is a-$\mathcal{C}'_0$-pseudo-coherent (respectively $\mathcal{C}'_0$-pseudo-coherent);

(ii) if $F \in \operatorname{ob} \mathrm{D}^*(\mathcal{C}_S)$ is acyclic in degrees > 0, then $u(F)$ is acyclic in degrees $> b$.

Then, if $F \in \operatorname{ob} \mathrm{D}^*(\mathcal{C}_S)$ is m-pseudo-coherent relative to $\mathcal{C}_0$ and acyclic in degrees $> n$, the object

$$u(F) \in \operatorname{ob} \mathrm{D}^*(\mathcal{C}'_{S'}), \qquad S' = f^{-1}(S),$$

is $\sup(m+b, n+a)$-pseudo-coherent relative to $\mathcal{C}'_0$ (respectively $(m+b)$-pseudo-coherent), and is acyclic in degrees $> n+b$. In particular, in the parenthesized case, if $F \in \operatorname{ob} \mathrm{D}^*(\mathcal{C}_S)$ is pseudo-coherent relative to $\mathcal{C}_0$, then $u(F)$ is pseudo-coherent relative to $\mathcal{C}'_0$.

Proof. We may restrict to the non-parenthesized case. First suppose that $F \in \operatorname{ob} \mathrm{D}^*(\mathcal{C}_S)$ is strictly perfect (2.1), with $F^i = 0$ for $i > n$. Then $u(F)$ is $(n+a)$-$\mathcal{C}'_0$-pseudo-coherent. We argue by induction on the number N of indices i such that $F^i \neq 0$. If $N = 1$, then $F = F^p[-p]$ for some $p \leq n$, so $u(F)$ is $(p+a)$-$\mathcal{C}'_0$-pseudo-coherent, hence a fortiori $(n+a)$-pseudo-coherent. If $N > 1$, there is an exact sequence

$$0 \longrightarrow F' \longrightarrow F \longrightarrow F'' \longrightarrow 0,$$

where F' and F'' are strictly perfect of length $< N-1$, and where $F'^i = F''^i = 0$ for $i > n$. Applying (2.5 b) to the distinguished triangle

$$u(F') \longrightarrow u(F) \longrightarrow u(F'') \longrightarrow u(F')[1].$$

and using the induction hypothesis, we get that $u(F)$ is $(n+a)$-pseudo-coherent.

Now pass to the general case: F is m-$\mathcal{C}_0$-pseudo-coherent and acyclic in degrees $> n$. After localizing, we may, by (2.10 a), suppose F strictly m-pseudo-coherent and such that $F^i = 0$ for $i > n$. There is then an exact sequence

$$0 \longrightarrow F' \longrightarrow F \longrightarrow F'' \longrightarrow 0,$$

where F'' is zero in degrees $\geq m$, and F' is strictly perfect and zero in degrees $> n$. In the distinguished triangle

$$u(F') \longrightarrow u(F) \longrightarrow u(F'') \longrightarrow u(F')[1].$$

the object $u(F'')$ is acyclic in degrees $> m+b$, hence $(m+b)$-pseudo-coherent, while $u(F')$ is $(n+a)$-pseudo-coherent by what was just proved. We conclude by (2.5 b).

Corollary 2.14. Let $\mathcal{C}_1$ be a strictly full additive sub-S-category of $\mathcal{C}$ such that

$$\mathcal{C}_0 \subset \mathcal{C}_1 \subset \mathcal{C}.$$

Assume that every object of $\mathcal{C}_1$ is $\mathcal{C}_0$-pseudo-coherent. Then:

(i) $\mathcal{C}_1$ is locally quasi-liftable in $\mathcal{C}$ (1.2), and locally quasi-stable under kernels of epimorphisms (1.2);

(ii) for $S \in \operatorname{ob} S$ and $F \in \operatorname{ob} \mathrm{D}(\mathcal{C}_S)$, in order that F be n-pseudo-coherent (respectively pseudo-coherent) relative to $\mathcal{C}_1$, it is necessary and sufficient that it be so relative to $\mathcal{C}_0$.

Proof. For (i), let $E \to F$ be an epimorphism in $\mathcal{C}_S$, with $F \in \operatorname{ob} \mathcal{C}_{1,S}$. Since F is $\mathcal{C}_0$-pseudo-coherent, hence a fortiori of $\mathcal{C}_0$-finite type, there exists, after localizing, an epimorphism $E' \to F$ with $E' \in \operatorname{ob} \mathcal{C}_{0,S}$. Using the quasi-liftability of $\mathcal{C}_0$ in $\mathcal{C}$, we may suppose, after localizing again, that this epimorphism factors through E; this gives the quasi-liftability of $\mathcal{C}_1$. On the other

hand, if $E \in \mathrm{ob}\,\mathcal{C}_S$ admits a finite right resolution by objects of $\mathcal{C}_1$, then E is $\mathcal{C}_0$-pseudo-coherent by (2.11 a), hence a fortiori of $\mathcal{C}_1$-finite type.

For (ii), it is enough to prove necessity. For this one may apply, at choice, (2.11 a) or (2.13), with $S' = S$, $\mathcal{C}' = \mathcal{C}$, $f = \mathrm{Id}$, $u = \mathrm{Id}$, and with $\mathcal{C}'_0$ and $\mathcal{C}_0$ replaced respectively by $\mathcal{C}_0$ and $\mathcal{C}_1$.

Scholium 2.14.1. There is therefore a largest strictly full additive sub-S-category of $\mathcal{C}$ giving the same notion of n-pseudo-coherence (respectively pseudo-coherence) as $\mathcal{C}_0$, namely the category formed by the $\mathcal{C}_0$-pseudo-coherent objects. This latter category is locally stable under kernels of epimorphisms.

Example 2.15. Let (S, A) be a ringed topos, and let $\mathcal{C}, \mathcal{C}_0$ be the S-categories considered in (1.3 d). The fibered category $\mathrm{D}(\mathcal{C})$ will often be denoted by $\mathrm{D}(S, A)$, or $\mathrm{D}_A(S)$, when one wants to suggest that the modules are left A-modules, or even simply $\mathrm{D}(S)$ if there is no ambiguity about A. We denote by S the final object of S, and put $\mathrm{D}(\mathcal{C}_S) = \mathrm{D}_A(S)$ (or $\mathrm{D}(S)$). An object of $\mathrm{D}(S)$ will be said to be n-pseudo-coherent (respectively pseudo-coherent) if it is n-$\mathcal{C}_0$-pseudo-coherent (respectively $\mathcal{C}_0$-pseudo-coherent), and similarly for the strict notions. The category fibered in $\mathrm{D}(\mathcal{C})$, denoted $\mathrm{D}(\mathcal{C})_{n-\mathcal{C}_0-\mathrm{coh}}$ (respectively $\mathrm{D}(\mathcal{C})_{\mathcal{C}_0-\mathrm{coh}}$) in (2.6), will be denoted $\mathrm{D}_A(S)_{n-\mathrm{coh}}$ (respectively $\mathrm{D}_A(S)_{\mathrm{coh}}$). One observes that, by (2.14), the same notion of pseudo-coherence is obtained if $\mathcal{C}_0$ is replaced by the S-category $\mathcal{C}_1$ defined by

$U \longmapsto$ the category of left A_U-modules locally direct summands of free finite-type modules.

If an A-module M is a direct summand of a free finite-type A-module, it does not follow in general that M is locally free of finite type. One does, however, have the following result.

Lemma 2.15.1. Suppose that S satisfies one of the following two hypotheses:

(i) S has enough points (SGA 4 IV 6.4), and for every point s of S, the left A_s-modules which are projective of finite type are free; this last condition is satisfied, for example, if $A_s/\operatorname{rad}(A_s)$ is a field or if $\operatorname{rad}(A_s)$ is nilpotent;

(ii) (S, A) is a "locally ringed" topos in the sense of [1], which means that A is commutative and that, for every $X \in \mathrm{ob}\,S$ and every $f \in \Gamma(X, A)$, one has

$$X = X_f \cup X_{1-f},$$

where X_f (respectively X_{1-f}) denotes the largest subobject of X on which f (respectively $1 - f$) is invertible.

Then every direct summand of a free finite-type left A-module is locally free of finite type.

Proof. Suppose first that (i) holds. We note that, if E and F are two A-modules and E is of finite presentation, the canonical arrow

$$\mathrm{Hom}(E, F)_s \longrightarrow \mathrm{Hom}(E_s, F_s)$$

is an isomorphism for every point s of S. It follows that, if E and F are both of finite presentation and if $E_s \xrightarrow{\sim} F_s$ at a point s of S, then there is an s-pointed object U of S such that $E|U \xrightarrow{\sim} F|U$. The conclusion follows at once.

Suppose next that (ii) holds. Let $n \in \mathbb{N}$, and let $\mathbb{D}^n$ denote the functor on the category of locally ringed topoi belonging to a fixed universe, defined by

$$T \longmapsto \Gamma(T, \mathcal{O}_T)^n.$$

It is known [1] that the functor $\mathrm{End}_{\mathbb{D}}(\mathbb{D}^n)$ is represented by

$$M_n = \operatorname{Spec} \mathbb{Z}[T_{ij}] \quad (1 \leq i \leq n, 1 \leq j \leq n),$$

endowed with the endomorphism U_n of $(\mathcal{O}_{M_n})^n$ defined by the matrix (T_{ij}). Now let

$$p : A^n \longrightarrow A^n$$

be a projector. We show that $p(A^n)$ is locally free of finite type. From what has just been said, there exists a morphism

$$s : S \longrightarrow M_n$$

of locally ringed topoi such that $s^*(u_n) = p$. We may interpret s as a point of M_n with values in $\Gamma(S, A)$, that is, as a matrix of order n with coefficients in $\Gamma(S, A)$. Since this matrix is a projector, s factors through the closed subscheme

$$i : P_n \hookrightarrow M_n$$

corresponding to projectors; say $S \xrightarrow{s'} P_n \xrightarrow{i} M_n$. Hence

$$p = s'^* i^*(u_n),$$

and we are done, because, by the assertion under hypothesis (i), the image of $i^*(u_n)$ is a locally free finite-type sheaf.

Corollary 2.16. Let

$$f : (S', A') \longrightarrow (S, A)$$

be a morphism of ringed topoi, defined by a functor $f^{-1} : S \to S'$ and a morphism of sheaves of rings $f^{-1}(A) \to A'$. Let $\mathrm{D}({}_{A'}S'_A)$ denote the derived category of A'-A-bimodules, left over A' and right over A, and let

$$\otimes^{\mathrm{L}}_A : \mathrm{D}^-({}_{A'}S'_A) \times_{S'} \mathrm{D}^-({}_AS) \longrightarrow \mathrm{D}^-({}_{A'}S')$$

be the derived functor of the tensor product

$$(E', E) \longmapsto E' \otimes_A f^{-1}(E).$$

Let $X \in \mathrm{ob}\, S$, put $X' = u(X)$, and let $E' \in \mathrm{ob}\, \mathrm{D}^-({}_{A'}X'_A)$, $E \in \mathrm{ob}\, \mathrm{D}^-({}_AX)$. If E' is m'-pseudo-coherent (as an object of $\mathrm{D}^-({}_AS')$) and acyclic in degrees $> n'$, and if E is m-pseudo-coherent and acyclic in degrees $> n$, then

$$E' \otimes^{\mathrm{L}}_A E$$

is $\sup(m + n', m' + n)$-pseudo-coherent and acyclic in degrees $> n + n'$.

Proof. After replacing S by S/X, we may suppose $X = S$, and apply (2.13) with

$$u = E' \otimes^{\mathrm{L}}_A : \mathrm{D}^-({}_AS) \longrightarrow \mathrm{D}^-({}_{A'}S').$$

Let $U \in \mathrm{ob}\, S$, let $U' = f^{-1}(U)$, and let E be a complex of left A_U-modules. If E is acyclic in degrees $> n$, then $E' \otimes^{\mathrm{L}}_A E$ is acyclic in degrees $> n + n'$, by the definition of $\otimes^{\mathrm{L}}_A$. On the other hand, if $E = (A_U)^p$, then

$$E' \otimes^{\mathrm{L}}_A E = (E'|U')^p,$$

which is m'-pseudo-coherent by hypothesis and (2.12). The conditions of (2.13) are therefore satisfied, with $a = m'$ and $b = n'$, whence the conclusion.

In particular:

Corollary 2.16.1. Under the hypotheses of (2.16), one has:

a) The functor

$$\mathrm{L}f^* : \mathrm{D}^-({}_AS) \longrightarrow \mathrm{D}^-({}_{A'}S')$$

(which is none other than the functor $A' \otimes_A^{\mathrm{L}}$) induces a functor

$$\mathrm{L}f^* : \mathrm{D}^-({}_A S)_{\mathrm{coh}} \longrightarrow \mathrm{D}^-({}_{A'} S')_{\mathrm{coh}}$$

(with the notation of (2.6)).

b) If A is commutative, the functor

$$\otimes_A^{\mathrm{L}} : \mathrm{D}^-(S) \times_S \mathrm{D}^-(S) \longrightarrow \mathrm{D}^-(S)$$

induces a functor

$$\otimes_A^{\mathrm{L}} : \mathrm{D}^-(S)_{\mathrm{coh}} \times_S \mathrm{D}^-(S)_{\mathrm{coh}} \longrightarrow \mathrm{D}^-(S)_{\mathrm{coh}}.$$

Exercise 2.16.2. Let S be a topos, and let $A \to A'$ be a morphism of rings of S. Assume one of the following hypotheses:

(i) $A \to A'$ is surjective, with nilpotent ideal as kernel;

(ii) the functor $A' \otimes_A -$, on the category of left A-modules, is exact and faithful.

Show that $E \in \mathrm{ob}\, \mathrm{D}^-({}_A S)$ is n-pseudo-coherent (respectively pseudo-coherent) if and only if

$$A' \otimes_A E \in \mathrm{ob}\, \mathrm{D}^-({}_{A'} S)$$

is n-pseudo-coherent (respectively pseudo-coherent).

Hints: first show that a left A-module L is of finite type if and only if $A' \otimes_A L$ is of finite type (cf. Bourbaki, Commutative Algebra, Chap. I, §3, Prop. 11 and Chap. II, §3, Prop. 4), and then reduce to this case by truncation, using (2.5) and (2.10 b).

3. Link with the classical notion of coherence

3.0. The hypotheses and notation are those of (2.0), except that $\mathcal{C}_0$ is no longer assumed locally quasi-stable under kernels of epimorphisms.

Definition 3.1. Let $F \in \mathrm{ob}\, \mathcal{C}_S$. We shall say that F is *precoherent* relative to $\mathcal{C}_0$ if, for every U over S and every morphism

$$u : E \longrightarrow F|U,$$

where $E \in \mathrm{ob}\, \mathcal{C}_{0,U}$, $\mathrm{Ker}(u)$ is of $\mathcal{C}_0$-finite type (1.2). We shall say that F is *coherent* relative to $\mathcal{C}_0$ if F is precoherent and of finite type.

Technical note. We introduce this notion here only as a technical intermediary; the only notion to retain is that of coherence.

Remark 3.2. Let $F \in \mathrm{ob}\, \mathcal{C}_S$. It is clear from the definitions that, if F is precoherent (respectively of finite type), then every subobject (respectively quotient) of F is precoherent (respectively of finite type).

Lemma 3.3.

a) Let

$$0 \longrightarrow F \longrightarrow G \longrightarrow H$$

be an exact sequence of $\mathcal{C}_S$. If G is of finite type and H is precoherent, then F is of finite type.

b) Let

$$F \longrightarrow G \longrightarrow H \longrightarrow 0$$

be an exact sequence of $\mathcal{C}_S$. If F is of finite type and G is precoherent, then H is precoherent.

c) Let

$$0 \longrightarrow F \longrightarrow G \longrightarrow H \longrightarrow 0$$

be an exact sequence of $\mathcal{C}_S$. If F and H are precoherent (respectively of finite type), then so is G.

Proof. a) After localizing, there is an epimorphism $G' \to G$ with $G' \in \mathrm{ob}\,\mathcal{C}_0$. Hence there is a commutative diagram with exact rows

$$\begin{array}{ccccccc} 0 & \longrightarrow & F' & \longrightarrow & G' & \longrightarrow & H \\ & & \downarrow & & \downarrow & & \downarrow{\scriptstyle \mathrm{Id}} \\ 0 & \longrightarrow & F & \longrightarrow & G & \longrightarrow & H. \end{array}$$

Since H is precoherent, F' is of finite type; but $F' \to F$ is an epimorphism, so F is of finite type.

b) Let U be over S, and let $H' \xrightarrow{f} H|U$ be a morphism of $\mathcal{C}_U$, with $H' \in \mathrm{ob}\,\mathcal{C}_{0,U}$. After a change of notation, we may suppose $U = S$. By the quasi-liftability of $\mathcal{C}_0$ in $\mathcal{C}$, there exists, after localizing, a commutative square

$$\begin{array}{ccc} G' & \xrightarrow{p} & H' \\ \downarrow & & \downarrow{\scriptstyle f} \\ G & \longrightarrow & H, \end{array}$$

where the horizontal arrows are epimorphisms and $G' \in \mathrm{ob}\,\mathcal{C}_0$. Since $\mathrm{Ker}(f)$ is a quotient of $\mathrm{Ker}(fp)$, it is enough to show that $\mathrm{Ker}(fp)$ is of finite type; hence we may suppose $H' = G'$. The arrows $F \to G$ and $H' \to G$ define

$$g : F \oplus H' \longrightarrow G.$$

Putting $K = \mathrm{Ker}(G \to H)$, we have a commutative diagram, with exact rows and with q an epimorphism,

$$\begin{array}{ccccccccc} 0 & \longrightarrow & F & \longrightarrow & F \oplus H' & \longrightarrow & H' & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle q} & & \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle f} & & \\ 0 & \longrightarrow & K & \longrightarrow & G & \longrightarrow & H & \longrightarrow & 0. \end{array}$$

The snake diagram shows that $\mathrm{Ker}(g) \to \mathrm{Ker}(f)$ is an epimorphism. But, since $F \oplus H'$ is of finite type and G is precoherent, $\mathrm{Ker}(g)$ is of finite type by a); hence we are done.

c) First prove the non-parenthesized assertion. Up to a change of notation, it is a matter of showing that, if $g : G' \to G$ is a morphism of $\mathcal{C}_S$, with $G' \in \mathrm{ob}\,\mathcal{C}_0$, then $\mathrm{Ker}(g)$ is of finite type. Let H' be the image of the composed arrow $G' \to H$. We have a commutative diagram with exact rows

$$\begin{array}{ccccccccc} 0 & \longrightarrow & F' & \longrightarrow & G' & \longrightarrow & H' & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle f} & & \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle h} & & \\ 0 & \longrightarrow & F & \longrightarrow & G & \longrightarrow & H & \longrightarrow & 0. \end{array}$$

Since h is a monomorphism, the snake diagram gives an isomorphism $\mathrm{Ker}(f) \xrightarrow{\sim} \mathrm{Ker}(g)$. But F' is of finite type by a), hence $\mathrm{Ker}(f)$ is of finite type, again by a). This proves the non-parenthesized assertion. For the parenthesized assertion, strictly speaking one cannot invoke (2.5 b), since $\mathcal{C}_0$ is not assumed locally quasi-stable under kernels of epimorphisms. After localizing, there are epimorphisms

$$F' \xrightarrow{u} F, \qquad H' \xrightarrow{v} H,$$

with $F', H' \in \mathrm{ob}\,\mathcal{C}_0$. After localizing further, we may suppose that v factors through G, whence a commutative diagram with exact rows

$$\begin{array}{ccccccccc} 0 & \longrightarrow & F' & \longrightarrow & F' \oplus H' & \longrightarrow & H' & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle u} & & \downarrow{\scriptstyle w} & & \downarrow{\scriptstyle v} & & \\ 0 & \longrightarrow & F & \longrightarrow & G & \longrightarrow & H & \longrightarrow & 0. \end{array}$$

Since u and v are epimorphisms, so is w, and this proves the assertion. The proof of (3.3) is complete.

It follows immediately that:

Corollary 3.4. The full (respectively strictly full) subcategory of $\mathcal{C}_S$ formed by coherent objects is stable under finite projective (respectively inductive) limits. In particular, the kernel, cokernel, and image of an arrow between two coherent objects are coherent. Let

$$E^0 \longrightarrow E^1 \longrightarrow E^2 \longrightarrow E^3 \longrightarrow E^4$$

be an exact sequence of $\mathcal{C}_S$. If E^0, E^1, E^3, E^4 are coherent, then E^2 is coherent as well.

Corollary 3.5. Suppose that the objects of $\mathcal{C}_0$ are $\mathcal{C}_0$-coherent (which in particular implies that $\mathcal{C}_0$ is locally quasi-stable under kernels of epimorphisms, that is, that we are under the conditions of (2.0)).

a) For $F \in \mathrm{ob}\,\mathcal{C}_S$, the following conditions are equivalent:

(i) F is of finite presentation;

(ii) F is coherent;

(iii) F is of finite ∞-presentation (2.8).

b) Let $F \in \mathrm{ob}\,\mathrm{D}^-(\mathcal{C}_S)$, and let $n \in \mathbb{Z}$. Then

$$F \text{ is } n\text{-pseudo-coherent} \iff \begin{array}{l} \mathrm{H}^i(F) \text{ is coherent for } i \geq n+1, \\ \text{and } \mathrm{H}^n(F) \text{ is of finite type.} \end{array}$$

In particular, for F to be pseudo-coherent it is necessary and sufficient that $\mathrm{H}^n(F)$ be coherent for every n.

Proof. Assertion a) and the implication $\Rightarrow$ in b) follow trivially from (3.4). The implication $\Leftarrow$ in b) follows at once from a) and (2.11 b).

Examples 3.6. Let (S, A) be a ringed topos, and let $\mathcal{C}, \mathcal{C}_0$ be the S-categories of (1.3 d), also as in (2.15). In order that the objects of $\mathcal{C}_0$ be coherent, it is necessary and sufficient that A be coherent, that is, precoherent. Here are examples where this is the case:

- A is constant with value a left noetherian ring (SGA 4 IX 2.1);
- S is the topos of sheaves of sets, for the Zariski topology, on a locally noetherian scheme S, and $A = \mathcal{O}_S$;
- S is the topos of sheaves of sets on a complex analytic space S, and $A = \mathcal{O}_S$.

On the other hand, the sheaf of continuous complex-valued functions on a topological space is not coherent in general.

Of course, if (S, A) is defined by a ringed space, the notion of coherence considered here coincides with the usual notion of Serre (EGA 0_I, 5.3.1).

Proposition 3.7. a) Let

$$f : (S', A') \longrightarrow (S, A)$$

be a morphism of ringed topoi. Assume that f is flat on the right, that is, that the functor $f^* = A' \otimes_A -$ is exact. There is, for $F \in \operatorname{ob} \mathrm{D}_A^-(S)$ and $G \in \operatorname{ob} \mathrm{D}_A^+(S)$, a functorial canonical arrow

$$f^*\mathrm{RHom}(F, G) \longrightarrow \mathrm{RHom}(f^*(F), f^*(G)).$$

This arrow is an isomorphism when F is pseudo-coherent.

b) Suppose A is commutative and coherent, and let $F \in \operatorname{ob} \mathrm{D}^-(S)$, $G \in \operatorname{ob} \mathrm{D}^+(S)$. If $\mathrm{H}^i(F)$ and $\mathrm{H}^i(G)$ are coherent for all i, then the same is true of $\mathrm{Ext}^i(F, G)$.

Proof. a) To define the arrow (cf. SGA 4 XVII), one may suppose that G has injective components, and one takes the composite arrow

$$f^* \operatorname{Hom}(F, G) \longrightarrow \operatorname{Hom}(f^*F, f^*G) \longrightarrow \mathrm{RHom}(f^*F, f^*G).$$

Let us show that it is an isomorphism for F pseudo-coherent. For brevity write T (respectively T') for the functor $f^*\mathrm{RHom}(\cdot, G)$ (respectively $\mathrm{RHom}(f^*\cdot, f^*G)$), and let $a \in \mathbb{Z}$ be such that $\mathrm{H}^i(G) = 0$ for $i < a$. It is clear that one has $TA \xrightarrow{\sim} T'A$, hence by dévissage $TF \xrightarrow{\sim} T'F$ for F strictly perfect (2.1). On the other hand, if F is acyclic in degrees $> n$, then TF and $T'F$ are acyclic in degrees $< a - n$. To verify that $TF \xrightarrow{\sim} T'F$ for F pseudo-coherent, the question being local, one may suppose F strictly n-pseudo-coherent; that is, there is a distinguished triangle

$$F' \longrightarrow F \longrightarrow F'' \longrightarrow F'[1].$$

with F' strictly perfect and F'' acyclic in degrees $> n - 1$. From this one obtains a morphism of distinguished triangles

$$\begin{array}{ccccc} TF'' & \to & TF & \to & TF' \\ \downarrow & & \downarrow & & \downarrow \\ T'F'' & \to & T'F & \to & T'F'. \end{array}$$

Now $TF' \xrightarrow{\sim} T'F'$, since F' is strictly perfect, and TF'' and $T'F''$ are acyclic in degrees $\leq a - n$. Writing the induced morphism on the exact cohomology sequences of the preceding triangles, one deduces that $TF \to T'F$ induces an isomorphism

$$\mathrm{H}^i(TF) \xrightarrow{\sim} \mathrm{H}^i(T'F)$$

for $i \leq a - n$. Since n may be chosen arbitrarily negative, this proves the assertion.

b) The proof is left as an exercise to the reader; see, for example, [H] II 3.3.

Remark 3.7.1. We shall see below (7.1.2) another case of compatibility of RHom with $\mathrm{L}f^*$.

Corollary 3.7.2. (cf. EGA 0_I, 5.2.7.) Let (S, A) be a ringed topos, let s be a point of S (SGA 4 VIII 7.8), and let

$$E, F \in \operatorname{ob} \mathrm{D}^b_{A,\mathrm{coh}}(S).$$

If $E_s \xrightarrow{\sim} F_s$, then there exists an s-pointed object U of S such that

$$E|U \xrightarrow{\sim} F|U.$$

Proof. Let $\alpha : E_s \to F_s$ and $\beta : F_s \to E_s$ be reciprocal isomorphisms. By (2.22 a), one has

$$\operatorname{Hom}(E, F)_s \xrightarrow{\sim} \operatorname{Hom}(E_s, F_s), \qquad \operatorname{Hom}(F, E)_s \xrightarrow{\sim} \operatorname{Hom}(F_s, E_s).$$

There are therefore a neighbourhood U of s and a section u (respectively v) of $\mathrm{Hom}(E,F)$ (respectively of $\mathrm{Hom}(F,E)$) over U such that $u_s = \alpha$ (respectively $v_s = \beta$). The morphisms $vu : E|U \to E|U$ and $uv : F|U \to F|U$ induce the identity at s; hence on a suitable V over U, as required.

4. Perfect complexes

4.0. In this section, S denotes a site, S an object of S, $\mathcal{C}$ a flat abelian S-category, and $\mathcal{C}_0$ a strictly full additive sub-S-category of $\mathcal{C}$ (1.1). Unless otherwise mentioned, we suppose that $\mathcal{C}_0$ is locally liftable in $\mathcal{C}$ and locally stable under kernels of epimorphisms (1.2).

Lemma 4.1. Let

$$u : E \longrightarrow F$$

be an arrow of $\mathrm{C}(\mathcal{C}_S)$. If E is strictly $\mathcal{C}_0$-perfect (2.1) and F is acyclic, then u is locally homotopic to zero.

Proof. One has to construct locally a homotopy k such that

$$u = dk + kd.$$

Since E is strictly perfect, there are $a, b \in \mathbb{Z}$, with $a \leq b$, such that $E^i = 0$ for $i \notin [a,b]$. Thus one may take $k^i = 0$ for $i \notin [a,b]$. We construct the k^i, for $i > a$, by descending induction on i. Suppose $k^i : E^i \to F^{i-1}$ has been constructed so that

$$u^i = k^{i+1}d_E^i + d_F^{i-1}k^i$$

for $i > n > a$. We show that, after localizing, there exists

$$k^{n-1} : E^{n-1} \longrightarrow F^{n-2}$$

such that

$$u^{n-1} = k^n d_E^{n-1} + d_F^{n-2}k^{n-1}.$$

By the induction hypothesis, the arrow

$$v^{n-1} = u^{n-1} - k^n d_E^{n-1} : E^{n-1} \longrightarrow F^{n-1}$$

factors through $Z^{n-1}(F)$. But $Z^{n-1}(F) = B^{n-1}(F)$, since F is acyclic. Since $\mathcal{C}_0$ is locally liftable in $\mathcal{C}$, it follows, after localizing, that there exists $k^{n-1} : E^{n-1} \to F^{n-2}$ such that $v^{n-1} = d_F^{n-2}k^{n-1}$, as required.

Corollary 4.2. Let

$$\begin{array}{ccc} P & & \\ {\scriptstyle v}\downarrow & & \\ F & \xleftarrow[f]{} & E \end{array}$$

be a diagram of $\mathrm{C}(\mathcal{C}_S)$, where P is strictly $\mathcal{C}_0$-perfect and f is a quasi-isomorphism. The set of X over S for which there exists an arrow

$$u : P_X \longrightarrow E_X$$

of $\mathrm{C}(\mathcal{C}_X)$ such that the diagram

$$\begin{array}{ccc} & & P_X \\ & \overset{u}{\nearrow} & \downarrow{\scriptstyle v_X} \\ E_X & \xrightarrow[f_X]{} & F_X \end{array}$$

is commutative in $\mathrm{K}(\mathcal{C}_X)$, is a refinement of S.

Proof. Let G be the cone of f. There is an exact sequence

$$\longrightarrow \mathrm{Hom}_{\mathrm{K}(\mathcal{C}_S)}(P,E) \longrightarrow \mathrm{Hom}_{\mathrm{K}(\mathcal{C}_S)}(P,F) \longrightarrow \mathrm{Hom}_{\mathrm{K}(\mathcal{C}_S)}(P,G) \longrightarrow .$$

Since G is acyclic, the image of v in $\mathrm{Hom}_{\mathrm{K}(\mathcal{C}_S)}(P,G)$ is locally zero by (4.1). Therefore, after localizing, there exists $u : P \to E$ such that $v = fu$ in $\mathrm{K}(\mathcal{C}_S)$, as required.

Corollary 4.3. Let $f : E \to F$ be a quasi-isomorphism of $\mathrm{C}(\mathcal{C}_S)$, with F strictly perfect relative to $\mathcal{C}_0$. The set of X over S for which there exists a quasi-isomorphism

$$g : F_X \longrightarrow E_X$$

such that $f_X g$ is homotopic to Id_{F_X}, is a refinement of S.

Proof. This is a special case of (4.2).

Scholium 4.4. Let $F \in \mathrm{ob}\,\mathrm{K}(\mathcal{C}_S)$. One may define, for example with the aid of a cleavage of $\mathcal{C}$ (SGA 1 VI 7.1), a category $(\mathrm{Qis}\,/F)$ fibered over S/S, whose fiber over X over S is the category $(\mathrm{Qis}\,/F_X)^\circ$, opposite to the category of quasi-isomorphisms with target F_X. One may then express (4.3) by saying that, if F is strictly perfect, the arrow Id_F is locally cofinal in $(\mathrm{Qis}\,/F)$.

Notation 4.5. Let $\mathcal{M}$ be a fibered S-category. Let $X \in \mathrm{ob}\,S$, and let $E, F \in \mathrm{ob}\,\mathcal{M}_X$. We shall denote by

$$\underline{\mathrm{Hom}}_{\mathcal{M}}(E,F)$$

the sheaf on S/X associated to the presheaf of S-morphisms from E to F in $\mathcal{M}$. For the definition of this presheaf, see [G] I 2.6. One must be careful that, even if $\mathcal{C}$ is a stack ([G]), the corresponding presheaf for $\mathcal{M} = \mathrm{K}(\mathcal{C})$ or $\mathrm{D}(\mathcal{C})$ is not in general a sheaf.

Corollary 4.6. Let $E, F \in \mathrm{ob}\,\mathrm{C}(\mathcal{C}_S)$, with E strictly perfect. The canonical arrow

$$\underline{\mathrm{Hom}}_{\mathrm{K}(\mathcal{C})}(E,F) \longrightarrow \underline{\mathrm{Hom}}_{\mathrm{D}(\mathcal{C})}(E,F)$$

is an isomorphism.

Proof. This is an immediate consequence of (4.4) and of the formula

$$\underline{\mathrm{Hom}}_{\mathrm{D}(\mathcal{C}_X)}(E_X,F_X) = \varinjlim_{(\mathrm{Qis}\,/E_X)^\circ} \underline{\mathrm{Hom}}_{\mathrm{K}(\mathcal{C}_X)}(\,\cdot\,,F_X)$$

for X over S.

Definition 4.7. Let $F \in \mathrm{ob}\,\mathrm{D}(\mathcal{C}_S)$, and let $a, b \in \mathbb{Z}$, with $a \leq b$. We shall say that F has $\mathcal{C}_0$-perfect amplitude contained in the interval $[a,b]$, and we shall write

$$\mathcal{C}_0\text{-}\,\mathrm{Parf}\,\text{-}\,\mathrm{amp}(F) \subset [a,b],$$

if the set of X over S for which there exists a quasi-isomorphism

$$F' \longrightarrow F$$

in $\mathrm{C}(\mathcal{C}_X)$, with F' strictly $\mathcal{C}_0$-perfect (2.1) and such that $F'^i = 0$ for $i \notin [a,b]$, is a refinement of S. By (4.3), this condition is equivalent to the one obtained by replacing "quasi-isomorphism in $\mathrm{C}(\mathcal{C}_X)$" by "isomorphism in $\mathrm{D}(\mathcal{C}_X)$." We shall say that F has finite $\mathcal{C}_0$-perfect amplitude if there are integers a and b such that $\mathcal{C}_0$-Parf-amp$(F) \subset [a,b]$. We shall say that F is $\mathcal{C}_0$-perfect if F is locally of finite $\mathcal{C}_0$-perfect amplitude.

Example 4.8. Let (S,A) be a ringed topos, let $\mathcal{C}$ be the S-category defined by

$$U \longmapsto \text{the category of left } A_U\text{-modules},$$

and let $\mathcal{C}_0$ be the sub-S-category defined by

$U \longmapsto$ the category of left A_U-modules which are direct summands of free finite-type modules.

The pair $(\mathcal{C}, \mathcal{C}_0)$ satisfies the hypotheses (4.0) by (1.3.1). An object F of $\mathrm{D}_A(S)$ (cf. (2.15)) will be said to have perfect amplitude contained in $[a, b]$ (respectively finite perfect amplitude, respectively to be perfect) if F has $\mathcal{C}_0$-perfect amplitude contained in $[a, b]$ (respectively the corresponding property). When the direct summands of free finite-type modules are locally free (cf. (2.15.1)), to say that F is perfect means that F is locally isomorphic, in $\mathrm{D}(S)$, to a bounded complex whose components are free of finite type.

Notation 4.9. We shall denote by $\mathrm{D}(\mathcal{C})_{\mathcal{C}_0\text{- Parf}}$, or $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$, the strictly full sub-$S$-category of $\mathrm{D}(\mathcal{C})$ formed by the $\mathcal{C}_0$-perfect objects. In the case of Example (4.8), we shall write $\mathrm{D}_A(S)_{\mathrm{Parf}}$, or $\mathrm{Parf}_A(S)$, or simply $\mathrm{Parf}(S)$ if no ambiguity about A is possible.

Proposition 4.10. The category $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$ is a triangulated sub-S-category of $\mathrm{D}(\mathcal{C})$ (1.1.4). The canonical functor

$$\mathrm{K}^b(\mathcal{C}_0) \longrightarrow \mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$$

(respectively

$$\mathrm{Tr}(\mathrm{K}^b(\mathcal{C}_0)) \longrightarrow \mathrm{Tr}(\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0))$$

(1.1.3)) induces an S-equivalence on the associated stacks ([G] II 2.2.4), which means:

(i) for every $X \in \mathrm{ob}\, S$ and all $E, F \in \mathrm{ob}\, \mathrm{K}^b(\mathcal{C}_{0,X})$ (respectively $\mathrm{Tr}(\mathrm{K}^b(\mathcal{C}_{0,X}))$), the canonical arrow

$$\mathrm{Hom}_{\mathrm{K}^b(\mathcal{C}_0)}(E, F) \longrightarrow \mathrm{Hom}_{\mathrm{D}(\mathcal{C})}(E, F)$$

(respectively

$$\mathrm{Hom}_{\mathrm{Tr}(\mathrm{K}^b(\mathcal{C}_0))}(E, F) \longrightarrow \mathrm{Hom}_{\mathrm{Tr}(\mathrm{D}(\mathcal{C}))}(E, F)$$

) is an isomorphism; and

(ii) every object of $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$ (respectively of $\mathrm{Tr}(\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0))$) is locally isomorphic in $\mathrm{D}(\mathcal{C})$ (respectively in $\mathrm{Tr}(\mathrm{D}(\mathcal{C}))$) to an object of $\mathrm{K}^b(\mathcal{C}_0)$ (respectively of $\mathrm{Tr}(\mathrm{K}^b(\mathcal{C}_0))$).

Proof. The non-parenthesized assertion (i) is a special case of (4.6), and the non-parenthesized assertion (ii) is true by the definition (4.7) and (4.9). It is clear, moreover, that $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$ is stable under translation of degrees. To prove that $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$ is a triangulated sub-S-category of $\mathrm{D}(\mathcal{C})$, it remains to show that, if

$$E \xrightarrow{u} F \longrightarrow G \longrightarrow E[1]. \qquad (*)$$

is a distinguished triangle of $\mathrm{D}(\mathcal{C})$ with E and F perfect, then G is perfect. After localizing, we may suppose that E and F are objects of $\mathrm{K}^b(\mathcal{C}_0)$. After localizing further, we may suppose, by the non-parenthesized assertion (i), that u is an arrow of $\mathrm{K}^b(\mathcal{C}_0)$; then G is perfect, since it is isomorphic to the cone of u, which is strictly perfect. Hence $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$ is indeed a triangulated sub-S-category of $\mathrm{D}(\mathcal{C})$. The preceding argument also proves the parenthesized assertion (ii). It remains to prove the parenthesized assertion (i). Let $X \in \mathrm{ob}\, S$, and let

$$E = (E_1 \xrightarrow{a_1} E_2 \xrightarrow{a_2} E_3 \xrightarrow{a_3} E_1[+1]), \quad F = (F_1 \xrightarrow{b_1} F_2 \xrightarrow{b_2} F_3 \xrightarrow{b_3} F_1[+1])$$

be distinguished triangles of $\mathrm{K}^b(\mathcal{C}_{0,X})$. We must show that

$$\mathrm{Hom}_{\mathrm{Tr}(\mathrm{K}^b(\mathcal{C}_0))}(E, F) \longrightarrow \mathrm{Hom}_{\mathrm{Tr}(\mathrm{D}(\mathcal{C}))}(E, F) \qquad (**)$$

is an isomorphism. By the non-parenthesized assertion (i), we already know that $(**)$ is injective. Let $(u_i) : E \to F$ be a morphism of triangles in $\mathrm{D}(\mathcal{C})$. After localizing, the non-parenthesized assertion (i) permits us to suppose that u_i, for $1 \leq i \leq 3$, is an arrow of $\mathrm{K}^b(\mathcal{C}_0)$. The arrow

$$u_{i+1}a_i - b_i u_i,$$

for $1 \leq i \leq 3$ (with the convention $u_4 = u_1$), is zero in $\mathrm{D}(\mathcal{C})$, hence locally zero in $\mathrm{K}^b(\mathcal{C}_0)$ by the non-parenthesized assertion (i). In other words, (u_i) locally defines a morphism of triangles in $\mathrm{K}^b(\mathcal{C}_0)$. This proves that $(**)$ is surjective and completes the proof of (4.10).

Remark 4.10.1. In (4.10), one may replace $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$ by

$$\mathrm{D}^*(\mathcal{C})_{\mathcal{C}_0\text{- Parf}} = \mathrm{D}^*(\mathcal{C}) \cap \mathrm{Parf}(\mathcal{C}, \mathcal{C}_0) \qquad (* = - \text{ or } b),$$

and nothing changes in the proof.

Complement 4.11. The triangulated structure of $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$ can be made more precise in terms of perfect amplitude (4.7). If $E \in \mathrm{ob}\,\mathrm{D}(\mathcal{C})$ has perfect amplitude contained in $[a, b]$, then $E[n]$ has perfect amplitude contained in $[a - n, b - n]$.

Let

$$E \longrightarrow F \longrightarrow G \longrightarrow E[1].$$

be a distinguished triangle of $\mathrm{D}(\mathcal{C})$. One may draw up a table analogous to (2.6), where the entries indicate perfect amplitudes and each row corresponds to an implication whose target is underlined:

E	F	G
$[a+1, b+1]$	$[a, b]$	$\underline{[a, b]}$
$[a, b]$	$\underline{[a, b]}$	$\underline{[a, b]}$
$\underline{[a, b]}$	$\underline{[a, b]}$	$[a-1, b-1]$.

From (4.10) one immediately deduces:

Corollary 4.12. Suppose that S is a punctual site. For $F \in \mathrm{ob}\,\mathrm{D}(\mathcal{C})$ to have perfect amplitude relative to $\mathcal{C}_0$ contained in $[a, b]$, it is necessary and sufficient that there exist a quasi-isomorphism $F' \to F$, with F' strictly perfect and such that $F'^i = 0$ for $i \notin [a, b]$. The canonical functors

$$\mathrm{K}^b(\mathcal{C}_0) \longrightarrow \mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$$

and

$$\mathrm{Tr}(\mathrm{K}^b(\mathcal{C}_0)) \longrightarrow \mathrm{Tr}(\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0))$$

are equivalences of categories.

Remark 4.12.1. When S is a punctual site, the objects of $\mathcal{C}_0$ are projective. When $\mathcal{C}_0$ contains all the projective objects of $\mathcal{C}$, one says "projective amplitude" instead of "$\mathcal{C}_0$-perfect amplitude."

Exposé I, continued: perfect amplitude, finite Tor-dimension, and rank

Remark 4.12.2. Let $\mathcal{C}$ be an abelian category (which may be regarded as fibered over a punctual site), and let $\mathcal{C}_0$ be a strictly full additive subcategory. Suppose that $\mathcal{C}_0$ is stable under kernels of epimorphisms and is quasi-liftable in $\mathcal{C}$. Then an acyclic object of $\mathrm{K}^b(\mathcal{C}_0)$ is not in general zero; hence there is no hope that the functor

$$\mathrm{K}^b(\mathcal{C}_0) \longrightarrow \mathrm{D}(\mathcal{C})$$

should be faithful. However, if $\mathrm{K}^{b,\mathrm{ac}}(\mathcal{C}_0)$ denotes the thick subcategory of $\mathrm{K}^b(\mathcal{C}_0)$ formed by the objects which are acyclic in $\mathcal{C}$, the canonical functor

$$\mathrm{K}^b(\mathcal{C}_0)/\mathrm{K}^{b,\mathrm{ac}}(\mathcal{C}_0) \longrightarrow \mathrm{D}(\mathcal{C})$$

is fully faithful.

Indications: one already knows from (2.7) that the functor

$$\mathrm{K}^-(\mathcal{C}_0)/\mathrm{K}^{-,\mathrm{ac}}(\mathcal{C}_0) \longrightarrow \mathrm{D}^-(\mathcal{C})$$

is fully faithful. Show, for example with the aid of the criterion of [V], 4.2 b)(ii), that the functor

$$\mathrm{K}^b(\mathcal{C}_0)/\mathrm{K}^{b,\mathrm{ac}}(\mathcal{C}_0) \longrightarrow \mathrm{K}^-(\mathcal{C}_0)/\mathrm{K}^{-,\mathrm{ac}}(\mathcal{C}_0)$$

is fully faithful.

Lemma 4.13. Let $F \in \mathrm{ob}\,\mathrm{D}(\mathcal{C}_S)$, and let $a, b, c \in \mathbb{Z}$ be such that $a \leq b$ and $a \leq c$. If F is of perfect amplitude contained in $[a, c]$ (4.7), and if $\mathrm{H}^i(F) = 0$ for $i > b$, then F is of perfect amplitude contained in $[a, d]$, where $d = \inf(b, c)$.

Proof. We may suppose $b \leq c$, and F strictly perfect with $F^i = 0$ for $i \notin [a, c]$. Then F is isomorphic to its truncation F' defined by

$$F'^i = F^i \quad (i < b), \qquad F'^b = Z^b(F), \qquad F'^i = 0 \quad (i > b).$$

But $Z^b(F)$ admits a finite right resolution by objects of $\mathcal{C}_0$, hence is locally an object of $\mathcal{C}_0$, whence the assertion.

Corollary 4.14. Let $F \in \mathrm{ob}\,\mathcal{C}_S$ and $n \in \mathbb{N}$. The following conditions are equivalent:

(i) $\mathrm{perf.amp}(F) \subset [-n, 0]$;

(ii) F locally admits a left resolution of length n by objects of $\mathcal{C}_0$, that is, the set of objects X over S such that there exists an exact sequence

$$0 \longrightarrow L^{-n} \longrightarrow L^{-n+1} \longrightarrow \cdots \longrightarrow L^0 \longrightarrow F_X \longrightarrow 0,$$

with $L^i \in \mathrm{ob}\,\mathcal{C}_{0,X}$ for all i, is a refinement of S.

Proof. This is an immediate consequence of (4.7) and (4.13).

Definition 4.14.1. We shall say that F is of perfect dimension $\leq n$, and shall write $\mathrm{perf.dim}(F) \leq n$, if F satisfies the equivalent conditions of (4.14). We shall call the perfect dimension of F the smallest integer n such that $\mathrm{perf.dim}(F) \leq n$; if there is no such integer, we shall say that F is of infinite perfect dimension.

When S is the punctual site and $\mathcal{C}_0$ is the full subcategory of $\mathcal{C}$ formed by the projective objects, the perfect dimension is just the usual projective dimension.

Proposition 4.15. Let $a, b, n \in \mathbb{Z}$, with $a \leq b$ and $n \geq 0$, and let $F \in \mathrm{ob}\,\mathrm{D}(\mathcal{C})$ be such that $F^i = 0$ (respectively $\mathrm{H}^i(F) = 0$) for $i \notin [a, b]$. If, for every $i \in [a, b]$, F^i (respectively $\mathrm{H}^i(F)$) is of perfect dimension $\leq n + (i - a)$, then F is of perfect amplitude contained in $[a - n, b]$. Consequently, if for every $i \in [a, b]$, F^i (respectively $\mathrm{H}^i(F)$) is perfect, then F is perfect.

Proof. Proceed by induction on b (with a and n fixed), by truncating F and applying (4.11), cf. the proof of (2.11).

Lemma 4.16. Let $a, b \in \mathbb{Z}$, $a \leq b$, and let $F \in \mathrm{ob}\,\mathrm{D}(\mathcal{C})$ be such that $F^i = 0$ for $i \notin [a, b]$. Suppose that $\mathrm{perf.amp}(F) \subset [a, b]$, and that $F^i \in \mathrm{ob}\,\mathcal{C}_0$ for $i > a$. Then F^a is locally an object of $\mathcal{C}_0$.

Proof. There is an exact sequence, obtained by truncating F,

$$0 \longrightarrow F' \longrightarrow F \longrightarrow F^a[-a] \longrightarrow 0,$$

with $\mathrm{perf.amp}(F') \subset [a+1, b+1]$. From (4.11) and (4.13) one deduces that $\mathrm{perf.dim}(F^a) = 0$, i.e. that F^a is locally an object of $\mathcal{C}_0$.

Proposition 4.17. Let $F', F'' \in \mathrm{ob}\,\mathrm{D}(\mathcal{C}_S)$, and let $a, b \in \mathbb{Z}$, with $a \leq b$. Consider the conditions:

(i) $\mathrm{perf.amp}(F') \subset [a, b]$ and $\mathrm{perf.amp}(F'') \subset [a, b]$;

(ii) $\mathrm{perf.amp}(F' \oplus F'') \subset [a, b]$.

Then (i) implies (ii). If $\mathcal{C}_0$ is locally stable under direct factors, i.e. if the relation $E' \oplus E'' \in \mathrm{ob}\,\mathcal{C}_0$, for $E', E'' \in \mathrm{ob}\,\mathcal{C}_X$ and $X \in \mathrm{ob}\,S$, implies that locally E' and E'' are objects of $\mathcal{C}_0$, then (i) and (ii) are equivalent.

Proof. The implication (i) $\Rightarrow$ (ii) is a particular case of (4.11). Let us prove the converse. Put $F = F' \oplus F''$. Since F is pseudo-coherent, F' and F'' are also pseudo-coherent (2.12). On the other hand, the relation $\mathrm{H}^i(F) = 0$ for $i \notin [a, b]$ implies $\mathrm{H}^i(F') = \mathrm{H}^i(F'') = 0$ for $i \notin [a, b]$. By (2.10 a), we may therefore suppose, after localizing, that F'^i and F''^i are in $\mathrm{ob}\,\mathcal{C}_0$ for $i \geq a+1$, and that $F'^i = F''^i = 0$ for $i > b$. Then, by truncating, we get $F'^i = F''^i = 0$ for $i < a$. Since $\mathrm{perf.amp}(F) \subset [a, b]$, it follows from (4.16) that F^a is locally an object of $\mathcal{C}_0$. But $F^a = F'^a \oplus F''^a$, hence F'^a and F''^a are locally objects of $\mathcal{C}_0$, since $\mathcal{C}_0$ is locally stable under direct factors.

Proposition 4.18. Let $(S', \mathcal{C}', \mathcal{C}'_0)$ be a triple satisfying the same hypotheses (4.0) as $(S, \mathcal{C}, \mathcal{C}_0)$. Let $f : S' \to S$ be a morphism of sites, defined by $f^{-1} : S \to S'$, and let

$$u : \mathrm{D}^*(\mathcal{C}) \longrightarrow \mathrm{D}^*(\mathcal{C}') \qquad (* = -, +, b)$$

be a functor over f (cf. (2.13)). If u sends objects of $\mathcal{C}_0$ to $\mathcal{C}'_0$-perfect complexes, then u defines a functor

$$\mathrm{D}^*(\mathcal{C})_{\mathcal{C}_0\text{-parf}} \longrightarrow \mathrm{D}^*(\mathcal{C}')_{\mathcal{C}'_0\text{-parf}}.$$

Proof. Let $F \in \mathrm{ob}\,\mathrm{D}^*(\mathcal{C})_{\mathcal{C}_0\text{-parf}}$. We show that $u(F) \in \mathrm{ob}\,\mathrm{D}^*(\mathcal{C}')_{\mathcal{C}'_0\text{-parf}}$. Since the question is local, one may suppose F strictly perfect. It remains only to use dévissage, taking into account the fact that $\mathrm{D}^*(\mathcal{C}')_{\mathcal{C}'_0\text{-parf}}$ is a triangulated subcategory of $\mathrm{D}^*(\mathcal{C}')$ (4.10).

Remark 4.18.1. Suppose that there exist $m, n \in \mathbb{Z}$, $m \leq n$, such that $F \in \mathrm{ob}\,\mathcal{C}_0$ implies

$$\mathcal{C}'_0\text{-}\,\mathrm{perf.amp}(u(F)) \subset [m, n].$$

Then, if $F \in \mathrm{ob}\,\mathrm{D}^*(\mathcal{C})$, one has

$$\mathcal{C}_0\text{-}\,\mathrm{perf.amp}(F) \subset [a, b] \quad \Rightarrow \quad \mathcal{C}'_0\text{-}\,\mathrm{perf.amp}(u(F)) \subset [a+m, b+n].$$

The proof is left as an exercise to the reader (use (4.11)).

Corollary 4.19. Under the hypotheses of (2.16), if $E' \in \mathrm{ob}\,\mathrm{D}^-(A, S')$ is perfect as an object of $\mathrm{D}^-(A, S')$, and $E \in \mathrm{ob}\,\mathrm{D}^-(A, S)$ is perfect, then

$$E' \overset{\mathrm{L}}{\otimes}_A E$$

is perfect.

Proof. We may suppose that $E' \in \mathrm{ob}\,\mathrm{D}^-(A, S'_A)$, where S' is the final object of S', and apply (4.18) to

$$u = E' \overset{\mathrm{L}}{\otimes}_A : \mathrm{D}^-(A, S) \longrightarrow \mathrm{D}^-(A, S').$$

In particular:

Corollary 4.19.1. a) The functor

$$\mathrm{L}f^* : \mathrm{D}^-(A, S) \longrightarrow \mathrm{D}^-(A, S')$$

induces a functor

$$\mathrm{L}f^* : \mathrm{D}^-(A, S)_{\mathrm{parf}} \longrightarrow \mathrm{D}^-(A, S')_{\mathrm{parf}}.$$

b) If A is commutative, the functor

$$\overset{\mathrm{L}}{\otimes}_A : \mathrm{D}^-(S) \times_S \mathrm{D}^-(S) \longrightarrow \mathrm{D}^-(S)$$

induces a functor

$$\overset{\mathrm{L}}{\otimes}_A : \mathrm{D}^-(S)_{\mathrm{parf}} \times_S \mathrm{D}^-(S)_{\mathrm{parf}} \longrightarrow \mathrm{D}^-(S)_{\mathrm{parf}}.$$

Remark 4.19.2. One can refine (4.19) in terms of perfect amplitude:

$$\mathrm{perf.\,amp}(E) \subset [a, b], \qquad \mathrm{perf.\,amp}(E') \subset [a', b'] \quad \Rightarrow \quad \mathrm{perf.\,amp}(E' \overset{\mathrm{L}}{\otimes}_A E) \subset [a + a', b + b'].$$

In particular,

$$\mathrm{perf.\,amp}(E) \subset [a, b] \quad \Rightarrow \quad \mathrm{perf.\,amp}(\mathrm{L}f^*(E)) \subset [a, b].$$

5. Finite Tor-dimension and perfection

5.0. The reader will surely have asked the question: what is missing from a pseudo-coherent complex E in order that it be perfect? Is it enough, for example, that E have bounded cohomology? The answer is no. Indeed, take for $\mathcal{C}$ the category of modules over a commutative noetherian ring A, and for $\mathcal{C}_0$ the full subcategory of projective A-modules of finite type. Any A-module of finite type E is pseudo-coherent and has bounded cohomology, but E is perfect only if, in addition, it is of finite projective dimension (or, equivalently, of finite Tor-dimension). This example suggests that the difference between a pseudo-coherent complex and a perfect complex lies in a question of cohomological dimension. This is what we shall now examine in the case of the category of modules of a ringed topos (cf. (3.3)). We shall need a few preliminary sorties on the notion of finite Tor-dimension. We shall be brief, since this question already appears in the literature: cf. [H] II 4 and SGA 4 XVII 4.1.9.

Proposition 5.1. Let (S, A) be a ringed topos, $X \in \mathrm{ob}\,S$, $F \in \mathrm{ob}\,\mathrm{D}^-(A, X)$, and let $m, n \in \mathbb{Z}$, with $m \leq n$. The following conditions are equivalent:

(i) F is isomorphic, in $\mathrm{D}^-(A, X)$, to a complex F' such that F'^i is flat for every i, and zero for $i \notin [m, n]$;

(ii) for every right A_X-module E, one has

$$\mathrm{H}^i(E \overset{\mathrm{L}}{\otimes}_A F) = 0 \quad \text{for } i \notin [m, n].$$

Proof. The implication (i) ⇒ (ii) is trivial; the implication (ii) ⇒ (i) follows, by truncation, from the following lemma.

Lemma 5.1.1. (cf. (4.16)). Let $F \in \mathrm{ob}\,\mathrm{D}^-(A,X)$. Suppose that F satisfies hypothesis (ii) of (5.1), that $F^i = 0$ for $i \notin [m,n]$, and that F^i is flat for $i \neq m$. Then F^m is flat.

Proof. There is a distinguished triangle

$$F' \longrightarrow F \qquad (+1: F \to F^m[-m],\ F^m[-m] \to F')$$

where F' has flat components and is zero outside the interval $[m+1,n]$ (suppose $m < n$). Apply the functor $E \overset{\mathrm{L}}{\otimes}_A \cdot$, for an arbitrary right A_X-module E, and write the exact cohomology sequence.

Definition 5.2. An object F of $\mathrm{D}^-(A,S)$ satisfying the equivalent conditions of (5.1) will be said to be of flat amplitude contained in the interval $[m,n]$, and we shall write

$$\mathrm{tor.amp}(F) \subset [m,n].$$

We shall say that F is of finite flat amplitude, or of finite Tor-dimension, if there exist integers m and n such that the preceding condition is satisfied.

5.3. Let $X \in \mathrm{ob}\,S$. We shall write $\mathrm{D}^-(A,X)_{\mathrm{torf}}$ for the full subcategory of $\mathrm{D}^-(A,X)$ formed by the objects of finite Tor-dimension. By criterion (ii) of (5.1), this is a triangulated subcategory of $\mathrm{D}^-(A,X)$. As X varies, the categories $\mathrm{D}^-(A,X)_{\mathrm{torf}}$ form a triangulated sub-S-category (1.1.4) of $\mathrm{D}^-(A,S)$, which we shall denote by $\mathrm{D}^-(S)_{A\text{-}\mathrm{torf}}$. The functor $\overset{\mathrm{L}}{\otimes}_A$ induces an exact S-functor

$$\overset{\mathrm{L}}{\otimes}_A : \mathrm{D}^b(S_A) \times_S \mathrm{D}(A/S)_{\mathrm{torf}} \longrightarrow \mathrm{D}^b(S_{\mathbb{Z}}).$$

5.4. In order that a left A-module F be of flat amplitude contained in $[-n,0]$, $n \in \mathbb{N}$, it is necessary and sufficient that F be of Tor-dimension $\leq n$ in the ordinary sense, that is, that F admit a left resolution of length n by flat A-modules.

5.5. Let $X \in \mathrm{ob}\,S$, and let $m,n \in \mathbb{Z}$, with $m \leq n$. In order that $F \in \mathrm{ob}\,\mathrm{D}^-(A,X)$ be of flat amplitude contained in $[m,n]$, it is necessary and sufficient that there exist a covering family $(X_i \to X)$ such that $F|X_i$ is of flat amplitude contained in $[m,n]$. In particular, if S/X is of finite type (SGA 4 VI 1.7), and if F is locally of finite Tor-dimension, then F is of finite Tor-dimension.

Proposition 5.6. Under the hypotheses of (2.16), if E' is of flat amplitude contained in $[m',n']$ as an object of $\mathrm{D}^-(A,S')$, and if E is of flat amplitude contained in $[m,n]$, then

$$E' \overset{\mathrm{L}}{\otimes}_A E$$

is of flat amplitude contained in $[m+m', n+n']$.

Proof. This is immediate: use form (5.1 (i)) of the notion of finite Tor-dimension and the fact that, if E is a flat left A-module, then $f^{-1}(E)$ is a flat left $f^{-1}(A)$-module (SGA 4 IV, App.).

In particular:

Corollary 5.6.1. a) The functor

$$\mathrm{L}f^* : \mathrm{D}^-(A,S) \longrightarrow \mathrm{D}^-(A,S')$$

induces a functor

$$\mathrm{L}f^* : \mathrm{D}(A,S)_{\mathrm{torf}} \longrightarrow \mathrm{D}(A,S')_{\mathrm{torf}}.$$

b) If A is commutative, the functor

$$\overset{\mathrm{L}}{\otimes}_A : \mathrm{D}^-(S) \times_S \mathrm{D}^-(S) \longrightarrow \mathrm{D}^-(S)$$

induces a functor

$$\overset{\mathrm{L}}{\otimes}_A : \mathrm{D}(S)_{\mathrm{torf}} \times_S \mathrm{D}(S)_{\mathrm{torf}} \longrightarrow \mathrm{D}(S)_{\mathrm{torf}}.$$

Remark 5.6.2. Let $E \in \mathrm{ob}\,\mathrm{D}^-(A,S)$, where S is the final object of S, and let $m,n \in \mathbb{Z}$, with $m \leq n$. If E is of flat amplitude contained in $[m,n]$, then so is E_s, for every point s of S. The converse is true if S has enough points; use form (5.1(ii)) of the notion of flat amplitude and the fact that $\overset{\mathrm{L}}{\otimes}_A$ commutes with passage to the fibers.

Exercises 5.7. a) Suppose that A is commutative and that (S',A') is faithfully flat over (S,A) (cf. (2.16.2)). In order that $E \in \mathrm{ob}\,\mathrm{D}^-(A,S)$[13] be of flat amplitude contained in $[m,n]$, it is necessary and sufficient that $f^*(E)$ have that property.

b) Let $F \in \mathrm{ob}\,\mathrm{D}^+(A,S)$[13]. Show the equivalence of the following conditions:

(i) F is isomorphic, in $\mathrm{D}^+(A,S)$, to a complex F' such that F'^i is injective for every i and zero for $i \notin [m,n]$;

(ii) for every left A_S-module E, one has $\mathrm{Ext}^i(E,F) = 0$ for $i \notin [m,n]$.

If F satisfies the preceding conditions, one says that F is of injective amplitude contained in $[m,n]$. The full subcategory of $\mathrm{D}^+(A,S)$ formed by the objects of finite injective amplitude is a triangulated subcategory, denoted $\mathrm{D}^+(A,S)_{\mathrm{injf}}$. Show that, if A is commutative, the functor

$$\mathrm{R}\,\mathrm{Hom} : \mathrm{D}(S)^\circ \times \mathrm{D}^+(S) \longrightarrow \mathrm{D}(S)$$

induces a functor

$$\mathrm{R}\,\mathrm{Hom} : \mathrm{D}(S)^\circ_{\mathrm{torf}} \times \mathrm{D}(S)_{\mathrm{injf}} \longrightarrow \mathrm{D}(S)_{\mathrm{injf}}.$$

We can now answer the question of (5.0) and state the main result of this section.

Theorem 5.8. Let (S,A) be a ringed topos, $E \in \mathrm{ob}\,\mathrm{D}(A,S)$, and let $m,n \in \mathbb{Z}$, with $m \leq n$. The following conditions are equivalent:

(i) $\mathrm{perf.amp}(E) \subset [m,n]$ (4.8);

(ii) E is $(m-1)$-pseudo-coherent (2.15) and $\mathrm{tor.amp}(E) \subset [m,n]$ (5.2).

Since "perfect" plainly implies "pseudo-coherent", one deduces:

Corollary 5.8.1. In order that E be perfect (4.8), it is necessary and sufficient that E be pseudo-coherent (2.15) and locally of finite Tor-dimension (5.2).

For the proof, we shall need a few lemmas.

Lemma 5.8.2. Let B be a ring of S. If E is a left A-module, G a right B-module, and F an A-B-bimodule (left over A, right over B), there is a canonical functorial homomorphism

$$\mathrm{Hom}_B(F,G) \otimes_A E \longrightarrow \mathrm{Hom}_B(\mathrm{Hom}_A(E,F),G). \tag{5.8.2.1}$$

[13] Here S denotes the final object of the topos S.

It is an isomorphism for G injective and E of finite presentation.

Proof. First define the arrow. By the adjunction formula dear to Cartan, it amounts to defining a homomorphism of B-modules:

$$\mathrm{Hom}_B(F,G)\otimes_A E\otimes_{\mathbb{Z}_S}\mathrm{Hom}_A(E,F)\longrightarrow G.^{14} \qquad (*)$$

There is a canonical homomorphism of A-B-bimodules

$$E\otimes_{\mathbb{Z}_S}\mathrm{Hom}_A(E,F)\longrightarrow F \qquad (**)$$

coming, by adjunction, from the identity arrow of $\mathrm{Hom}_A(E,F)$. Similarly, there is a canonical homomorphism of B-modules

$$\mathrm{Hom}_B(F,G)\otimes_A F\longrightarrow G. \qquad (***)$$

We then define (*) as the composite of (**) and (***). To see that the arrow (5.8.2.1) is an isomorphism when G is injective and E is of finite presentation, it is enough to note that, if G is injective, the source and the target of the arrow are right-exact functors in E, and that the arrow induces the identity for $E=A$.

Here is now a particular case of (5.8).

Lemma 5.8.3. Let E be a left A-module. The following conditions are equivalent:

(i) E is locally a direct factor of a free module of finite type;

(ii) E is flat and of finite presentation.

Proof (after Bourbaki, Alg. comm., Chap. I, §2, Exer. 15). It is clear that (i) implies (ii). Let us prove (ii) $\Rightarrow$ (i). By (1.3.1), it is enough to show that the functor $\mathrm{Hom}_A(E,\cdot)$ is exact. Let

$$F\longrightarrow F''\longrightarrow 0$$

be an exact sequence of left A-modules. We must show that the sequence

$$\mathrm{Hom}_A(E,F)\longrightarrow\mathrm{Hom}_A(E,F'')\longrightarrow 0$$

is exact. For this it is enough to prove that, for every injective $\mathbb{Z}_S$-module I, the sequence obtained by applying the functor $\mathrm{Hom}_{\mathbb{Z}_S}(\cdot,I)$ is exact. But there is a commutative diagram, where the vertical arrows are the canonical arrows of (3.17.1):

$$\begin{array}{ccccc} 0 & \to & \mathrm{Hom}_{\mathbb{Z}_S}(F'',I)\otimes_A E & \to & \mathrm{Hom}_{\mathbb{Z}_S}(F,I)\otimes_A E \\ & & \downarrow & & \downarrow \\ 0 & \to & \mathrm{Hom}_{\mathbb{Z}_S}(\mathrm{Hom}_A(E,F''),I) & \to & \mathrm{Hom}_{\mathbb{Z}_S}(\mathrm{Hom}_A(E,F),I). \end{array}$$

The vertical arrows are isomorphisms by (5.8.2). The top row is exact because E is flat. Hence the bottom row is exact, q.e.d.

Proof of (5.8). The implication (i) $\Rightarrow$ (ii) follows trivially from the definitions. Let us prove (ii) $\Rightarrow$ (i). Since the question is local, one may suppose E strictly $(m-1)$-pseudo-coherent. Since, on the other hand, E is acyclic in degrees $<m$, the truncation arrow

$$\begin{array}{ccccccc} \cdots & \to & E^{m-1} & \to & E^m & \to & E^{m+1}\to\cdots \\ & & \downarrow & & \downarrow & & \downarrow \\ \cdots & \to & 0 & \to & E^m/B^m & \to & E^{m+1}\to\cdots \end{array}$$

[14] We write S for the final object of the topos S, and $\mathbb{Z}_S$ for the constant sheaf with value $\mathbb{Z}$.

is a quasi-isomorphism. Let E' be the truncated complex. By construction, E' is of flat amplitude contained in $[m,n]$, and E'^i is free of finite type for $i > m$. Therefore, by (5.1.1), E'^m is flat. On the other hand there is a distinguished triangle

$$E'^m[-m] \xrightarrow{+1} E'' \longrightarrow E'$$

where E'' is strictly perfect. By (2.6), $E'^m[-m]$ is $(m-1)$-pseudo-coherent; i.e. by (2.9), E'^m is of finite presentation. We conclude from (5.8.3) that E'^m is locally a direct factor of a free module of finite type, hence that $\operatorname{perf.amp}(E) \subset [m,n]$.

Remarks 5.8.4. a) Using (2.5), one recovers the fact that perfect complexes form a triangulated subcategory of $\mathrm{D}(A,S)$.

b) A perfect complex, even with bounded cohomology, is not necessarily of finite Tor-dimension. It is so, however, if S is of finite type (5.5). Write $\mathrm{D}(A,S)_{\mathrm{parf}}$ for the full sub-S-category of $\mathrm{D}^b(A,S)$ formed by perfect complexes of finite Tor-dimension. It follows at once from (2.16.1 b) and (5.3) that, if A is commutative, the functor $\overset{\mathrm{L}}{\otimes}_A$ induces a functor

$$\overset{\mathrm{L}}{\otimes}_A : \mathrm{D}(S)_{\mathrm{parf}} \times_S \mathrm{D}^b(S)_{\mathrm{coh}} \longrightarrow \mathrm{D}^b(S)_{\mathrm{coh}}.$$

This formula is the starting point for the theory of intersections on schemes. Note, on the other hand, that the derived tensor product of two pseudo-coherent complexes with bounded cohomology is not, in general, of bounded cohomology.

Corollary 5.9. Suppose that $S = (\mathrm{Ens})$ (so that A "is" an ordinary ring) and that every left A-module is of finite Tor-dimension; this is the case, for example, if A is of finite global cohomological dimension, cf. (MULT VI 2.6) and (EGA 0_{IV} 17.2.8). Then

$$\text{(i)}\quad \mathrm{D}^b(A,S) = \mathrm{D}(A,S)_{\mathrm{torf}}, \qquad \text{and} \qquad \text{(ii)}\quad \mathrm{D}^b(A,S)_{\mathrm{coh}} = \mathrm{D}(A,S)_{\mathrm{parf}}.$$

In other words, in order that $E \in \operatorname{ob}\mathrm{D}(A,S)$ be of finite Tor-dimension (respectively finite Tor-dimension and perfect), it is necessary and sufficient that E have bounded cohomology (respectively bounded and pseudo-coherent cohomology).

Proof. By (5.8), it is enough to prove (i). Let $E \in \operatorname{ob}\mathrm{D}^b(A,S)$. We may suppose, after extending E by 0, that $E \in \operatorname{ob}\mathrm{D}^b(A,S)$, where S is the final object of S. By induction on the number of non-zero cohomology objects of E, one is reduced, by dévissage, to the case where E is an ordinary A-module; then one wins.

More generally, one may state:

Corollary 5.10. Let $X \in \operatorname{ob} S$. Suppose that S/X has enough points (SGA 4 IV 6.4.1) and that, for every point s of S/X, every left A_s-module is of finite Tor-dimension. Then

$$\mathrm{D}^b(A,X)_{\mathrm{coh}} = \mathrm{D}^b(A,X)_{\mathrm{parf}}.$$

Equivalently, in order that $E \in \operatorname{ob}\mathrm{D}^b(A,X)$ be pseudo-coherent, it is necessary and sufficient that E be perfect.

Proof. Let $E \in \operatorname{ob}\mathrm{D}^b(A,X)_{\mathrm{coh}}$ and let s be a point of S/X. One must show that E is perfect in a neighbourhood of s, that is, that there exists an s-pointed object U of S over X such that $E|U$ is perfect. Now, since the functor s^* is exact, (2.16.1 a) gives $E_s \in \operatorname{ob}\mathrm{D}^b(A_s)_{\mathrm{coh}}$. Hence, by (5.9), E_s is perfect. The assertion is therefore a consequence of (3.7.2) and of the following lemma.

Lemma 5.10.1. Let s be a point of S, and let $F \in \mathrm{ob}\,\mathrm{D}(A_s)_{\mathrm{parf}}$. There exist an s-pointed object U of S and $F' \in \mathrm{ob}\,\mathrm{D}(A_U)_{\mathrm{parf}}$ such that $F'_s = F$.

Proof. This is evident if F is a free A_s-module of finite type. Suppose now that F is projective of finite type, hence the image of a projector

$$p : L \longrightarrow L,$$

where L is free of finite type. There is then a neighbourhood U of s, a free A_U-module L', and a homomorphism $p' : L' \to L'$ such that $p'_s = p$. Since $p_s^2 = p_s$, we may suppose, after shrinking U, that $p'^2 = p'$. Thus $F' = \mathrm{Im}(p')$ is a direct factor of L' and satisfies $F'_s = F$. The case where F is strictly perfect, that is, a bounded complex made up of projective modules of finite type, follows immediately.

Examples 5.11. Corollary (5.10) applies in particular when (S, A) is defined by a locally ringed space in regular local rings, for example a regular scheme or a smooth complex analytic space over $\mathbb{C}$.

6. Rank of a perfect complex

6.0. Let $(X, \mathcal{O}_X)$ be a ringed space in local rings. It is well known that one can attach, to every locally free sheaf of finite type L on an open set U of X, a function $\mathrm{rg}_U(L)$, locally constant on U and with integral values, called the rank of L. The family of functions $\mathrm{rg}_U(L)$ is characterized by the following properties:

(i) if $V \subset U$ is an inclusion of open sets, then $\mathrm{rg}_V(L|V) = \mathrm{rg}_U(L)|V$;

(ii) for every exact sequence of locally free $\mathcal{O}_U$-modules of finite type

$$0 \longrightarrow L' \longrightarrow L \longrightarrow L'' \longrightarrow 0,$$

one has $\mathrm{rg}_U(L) = \mathrm{rg}_U(L') + \mathrm{rg}_U(L'')$;

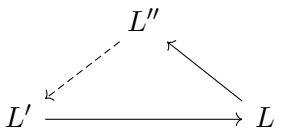
(iii) $\mathrm{rg}_X(\mathcal{O}_X) = 1$.

We propose in this section to extend the notion of rank to perfect complexes.

Definition 6.1 (cf. SGA 5 VIII 2). Let $\mathcal{C}$ be an additive (respectively triangulated) category, and let F be an abelian group. A function

$$f : \mathrm{ob}(\mathcal{C}) \longrightarrow F$$

is said to be an additive function from $\mathcal{C}$ to F if, for all $L, L', L'' \in \mathrm{ob}(\mathcal{C})$ such that $L \simeq L' \oplus L''$ (respectively such that there is a distinguished triangle



), one has

$$f(L) = f(L') + f(L'').$$

The additive functions from $\mathcal{C}$ to F form an abelian group, denoted $\mathrm{Add}(\mathcal{C}, F)$.

6.2. Let $\mathcal{C}$ be a triangulated category, and let f be an additive function from $\mathcal{C}$ to an abelian group F. Then f induces an additive function on the underlying additive category $\mathcal{C}^{\mathrm{ad}}$ of $\mathcal{C}$; hence an inclusion

$$\mathrm{Add}(\mathcal{C}, F) \subset \mathrm{Add}(\mathcal{C}^{\mathrm{ad}}, F).$$

In particular, $f(0) = 0$ and $f(L) = f(M)$ if $L \simeq M$. On the other hand,

$$f(L[n]) = (-1)^n f(L)$$

for all $L \in \mathrm{ob}(\mathcal{C})$ and $n \in \mathbb{Z}$.

6.3. Let $\mathcal{C}$ be an additive (respectively triangulated) category. The group $\mathrm{Add}(\mathcal{C}, F)$ depends functorially on F. The functor $\mathrm{Add}(\mathcal{C}, \cdot)$ is representable (cf. SGA 5 VIII 2) by an abelian group, denoted $k(\mathcal{C})$[15], endowed with an additive application

$$\mathrm{cl}_{\mathcal{C}} : \mathrm{ob}(\mathcal{C}) \longrightarrow k(\mathcal{C}).$$

If $\mathcal{C}$ is additive, one takes for $k(\mathcal{C})$ the symmetrized monoid of isomorphism classes of objects of $\mathcal{C}$. If $\mathcal{C}$ is triangulated, one takes for $k(\mathcal{C})$ the quotient of the free abelian group generated by $\mathrm{ob}(\mathcal{C})$ by the relations identifying L with $L' + L''$ whenever there is a distinguished triangle

$$L' \longrightarrow L \longrightarrow L'' \longrightarrow L'[1].$$

The group $k(\mathcal{C})$ depends functorially on $\mathcal{C}$, with respect to additive (respectively exact) functors. If $u, u' : \mathcal{C} \to \mathcal{D}$ are isomorphic additive (respectively exact) functors, then $k(u) = k(u')$.

If $\mathcal{C}$ is a triangulated category, one has a canonical epimorphism

$$k(\mathcal{C}^{\mathrm{ad}}) \longrightarrow k(\mathcal{C})$$

(cf. (6.2)).

Lemma 6.4. Let $\mathcal{C}$ be an additive category. The canonical functor

$$\mathcal{C} \longrightarrow \mathrm{K}^b(\mathcal{C})$$

induces an isomorphism, functorial in $\mathcal{C}$,

$$k(\mathcal{C}) \xrightarrow{\sim} k(\mathrm{K}^b(\mathcal{C})).$$

Proof. This is an immediate consequence of the following formula, which follows trivially from (6.2):

$$f(L) = \sum_i (-1)^i f(L^i) \tag{6.4.1}$$

for $L \in \mathrm{ob}\,\mathrm{K}^b(\mathcal{C})$ and f an additive function on $\mathrm{K}^b(\mathcal{C})$.

Definition 6.5. Let S be a category, $\mathcal{C}$ an additive (respectively triangulated) S-category (1.1.1), and F an abelian presheaf on S. A family of functions

$$f_X : \mathrm{ob}(\mathcal{C}_X) \longrightarrow F(X), \qquad X \in \mathrm{ob}\, S,$$

is said to be an additive S-function from $\mathcal{C}$ to F if the following conditions are satisfied:

(i) for every $X \in \mathrm{ob}\, S$, f_X is an additive function (6.1);

[15] We shall not use here the usual notation $K(\mathcal{C})$, since $K(\mathcal{C})$ already denotes, when $\mathcal{C}$ is additive, the category of complexes of $\mathcal{C}$ "up to homotopy."

(ii) for every arrow $u : X \to Y$ of S, the following diagram is commutative:

$$\begin{array}{ccc} \mathrm{ob}\,\mathcal{C}_Y & \xrightarrow{f_Y} & F(Y) \\ {\scriptstyle u^*}\downarrow & & \downarrow{\scriptstyle F(u)} \\ \mathrm{ob}\,\mathcal{C}_X & \xrightarrow[f_X]{} & F(X). \end{array}$$

The additive S-functions from $\mathcal{C}$ to F form an abelian group, denoted $\mathrm{Add}_S(\mathcal{C}, F)$.

Remarks 6.6. **a)** Let $\mathcal{C}^{\mathrm{is}}$ denote the fibered S-category whose fiber over $X \in \mathrm{ob}\,S$ is the category with the same objects as $\mathcal{C}_X$ but whose arrows are the isomorphisms of $\mathcal{C}_X$. Let $\underline{F}$ denote the fibered S-category whose fiber over $X \in \mathrm{ob}\,S$ is the discrete category (i.e. the only arrows are identities) $F(X)$, the inverse-image functor by $u \in \mathrm{Fl}(S)$ being $F(u)$. Then an additive S-function from $\mathcal{C}$ to F is simply a Cartesian S-functor from $\mathcal{C}^{\mathrm{is}}$ to $\underline{F}$, inducing on each fiber an additive function in the sense of (6.1). It will be convenient for us to interpret additivity as follows. Suppose, for definiteness, that $\mathcal{C}$ is triangulated. The category

$$\mathrm{Cart}_S(\mathcal{C}^{\mathrm{is}}, \underline{F})$$

(respectively $\mathrm{Cart}_S(\mathrm{Tr}(\mathcal{C})^{\mathrm{is}}, \underline{F})$ (1.1.2)) of Cartesian S-functors from $\mathcal{C}^{\mathrm{is}}$ (respectively $\mathrm{Tr}(\mathcal{C})^{\mathrm{is}}$) to $\underline{F}$ is the discrete category associated to an abelian group, and there is a homomorphism

$$\rho : \mathrm{Cart}_S(\mathcal{C}^{\mathrm{is}}, \underline{F}) \longrightarrow \mathrm{Cart}_S(\mathrm{Tr}(\mathcal{C})^{\mathrm{is}}, \underline{F}),$$

defined by

$$\rho(f)(T) = f(L) - f(L') - f(L'')$$

for $f \in \mathrm{Cart}_S(\mathcal{C}^{\mathrm{is}}, \underline{F})$ and $T = (L' \to L \to L'' \to L'[1]) \in \mathrm{ob}\,\mathrm{Tr}(\mathcal{C})$. To say that $f \in \mathrm{Cart}_S(\mathcal{C}^{\mathrm{is}}, \underline{F})$ is additive means that $\rho(f) = 0$, or equivalently that one has a functorial canonical exact sequence

$$0 \longrightarrow \mathrm{Add}_S(\mathcal{C}, F) \longrightarrow \mathrm{Cart}_S(\mathcal{C}^{\mathrm{is}}, \underline{F}) \xrightarrow{\rho} \mathrm{Cart}_S(\mathrm{Tr}(\mathcal{C})^{\mathrm{is}}, \underline{F}). \tag{6.6.1}$$

b) Let $u : X \to Y$ be an arrow of S. The inverse-image functors by u, being all isomorphic to one another, define by (6.3) a unique homomorphism

$$k(Y) \longrightarrow k(X).$$

Consequently, $X \mapsto k(X)$ defines an abelian presheaf on S, denoted $k(\mathcal{C})$. An additive S-function from $\mathcal{C}$ to F is then simply interpreted as a homomorphism of presheaves

$$k(\mathcal{C}) \longrightarrow F,$$

or in other words

$$\mathrm{Add}_S(\mathcal{C}, F) = \mathrm{Hom}(k(\mathcal{C}), F).$$

The presheaf $k(\mathcal{C})$ of course depends functorially on $\mathcal{C}$ with respect to additive (respectively exact) S-functors.

Proposition 6.7. Let S be a site, $\mathcal{C}$ a flat abelian S-category, and $\mathcal{C}_0$ a strictly full additive sub-S-category of $\mathcal{C}$ satisfying the hypotheses (4.0). Then the morphism of abelian presheaves

$$k(\mathcal{C}_0) \longrightarrow k(\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)) \qquad \text{(cf. (4.9))}$$

induced by the inclusion of $\mathcal{C}_0$ in $\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0)$, defines an isomorphism on the associated sheaves. In other words, for every abelian sheaf F on S, the restriction homomorphism

$$\mathrm{Add}_S(\mathrm{Parf}(\mathcal{C}, \mathcal{C}_0), F) \longrightarrow \mathrm{Add}_S(\mathcal{C}_0, F)$$

is an isomorphism.

Proof. Let F be an abelian sheaf on S. We show that the arrow

$$\mathrm{Add}_S(\mathrm{Parf}(\mathcal{C},\mathcal{C}_0),F) \longrightarrow \mathrm{Add}_S(\mathcal{C}_0,F)$$

is an isomorphism. It factors as

$$\mathrm{Add}_S(\mathrm{Parf}(\mathcal{C},\mathcal{C}_0),F) \xrightarrow{a} \mathrm{Add}_S(\mathrm{K}^b(\mathcal{C}_0),F) \xrightarrow{b} \mathrm{Add}_S(\mathcal{C}_0,F).$$

By (6.4), the arrow b is an isomorphism. We are reduced to proving that a is an isomorphism.

Consider the following commutative diagram, whose rows are exact by (6.6.1), and whose vertical arrows are the restriction arrows:

$$\begin{array}{ccccccc} 0 & \to & \mathrm{Add}_S(\mathrm{Parf}(\mathcal{C}),F) & \to & \mathrm{Cart}_S(\mathrm{Parf}(\mathcal{C})^{\mathrm{is}},\underline{F}) & \to & \mathrm{Cart}_S(\mathrm{Tr}(\mathrm{Parf}(\mathcal{C}))^{\mathrm{is}},\underline{F}) \\ & & \downarrow a & & \downarrow & & \downarrow \\ 0 & \to & \mathrm{Add}_S(\mathrm{K}^b(\mathcal{C}_0),F) & \to & \mathrm{Cart}_S(\mathrm{K}^b(\mathcal{C}_0)^{\mathrm{is}},\underline{F}) & \to & \mathrm{Cart}_S(\mathrm{Tr}(\mathrm{K}^b(\mathcal{C}_0))^{\mathrm{is}},\underline{F}). \end{array}$$

Since F is a sheaf, $\underline{F}$ is a stack (G II 2.2.4); hence, by (4.10), the two right vertical arrows are isomorphisms. The same is therefore true of a, q.e.d.

Remark 6.7.1 (cf. 4.10.1). In (6.7), one may replace $\mathrm{Parf}(\mathcal{C},\mathcal{C}_0)$ by $\mathrm{D}^*(\mathcal{C})_{\mathcal{C}_0\text{-parf}}$ ($* = -$ or b).

6.8. Let (S,A) be a ringed topos, and let $\mathcal{C}$ and $\mathcal{C}_0$ be the fibered S-categories considered in (4.8). There are homomorphisms of abelian presheaves

$$k(\mathcal{C}_0) \xrightarrow{\alpha} k(\mathrm{D}^-(A,S)_{\mathrm{parf}}) \xrightarrow{\beta} k(\mathrm{Parf}(A,S)),$$

which, by (6.7), induce isomorphisms on the associated sheaves. The homomorphism α is compatible with inverse images: that is, if

$$u : (S',A') \longrightarrow (S,A)$$

is a morphism of ringed topoi, there is a commutative diagram, whose vertical arrows are induced by the functor $\mathrm{L}u^*$ (cf. (4.19.1)):

$$\begin{array}{ccc} k(\mathcal{C}_0) & \longrightarrow & k(\mathrm{D}^-(A,S)_{\mathrm{parf}}) \\ \downarrow & & \downarrow \\ k(\mathcal{C}'_0) & \longrightarrow & k(\mathrm{D}^-(A',S')_{\mathrm{parf}}), \end{array}$$

where $\mathcal{C}'_0$ is defined analogously to $\mathcal{C}_0$. If A is commutative, the derived tensor product endows $k(\mathcal{C}_0)$ and $k(\mathrm{D}^-(A,S)_{\mathrm{parf}})$ with structures of presheaves of rings (cf. (4.19.1)), and α is a homomorphism of presheaves of rings.

6.9. In the situation of (6.8), suppose that (S,A) is locally ringed (cf. (2.15.1)). Then, for every $X \in \mathrm{ob}\, S$, $\mathcal{C}_{0,X}$ is the category of locally free A_X-modules of finite type. Let $\mathcal{C}_1$ be the fibered S-category defined by

$$X \longmapsto \text{the category of free } A_X\text{-modules of finite type.}$$

It is clear that $\mathcal{C}_1$ satisfies the hypotheses (4.0). An object of $\mathrm{D}(S)$ is perfect if and only if it is perfect relative to $\mathcal{C}_1$. There are homomorphisms of abelian presheaves

$$k(\mathcal{C}_1) \longrightarrow k(\mathcal{C}_0) \longrightarrow k(\mathrm{D}^-(S)_{\mathrm{parf}}) \longrightarrow k(\mathrm{Parf}(S))$$

(the two on the left being homomorphisms of presheaves of rings), which, by (6.7), induce isomorphisms on the associated sheaves. We shall show that the associated sheaves are in fact canonically isomorphic to the constant sheaf $\mathbb{Z}_S$.

Lemma 6.10. Let (S, A) be a locally ringed topos, let U be an object of S distinct from the empty object, and let $p, q \in \mathbb{N}$. If

$$A_U^p \simeq A_U^q,$$

then $p = q$.

Proof. By an argument similar to that given in the proof of (2.15.1), one is reduced to the case where (S, A) is the locally ringed topos defined by a prescheme; in this case the assertion is trivial: take a point in U.

Definition 6.11. The rank, denoted rg, is the additive S-function from $\mathcal{C}_1$ to $\mathbb{Z}_S$ defined by

$$\operatorname{rg}(L) = p \quad \text{if } L \simeq A_X^p, \qquad X \neq \varnothing,$$

$$\operatorname{rg}(L) = 0 \quad \text{if } L \in \operatorname{ob} \mathcal{C}_{1,X}, \qquad X = \varnothing.$$

By (6.7), the rank function extends uniquely to an additive S-function from $\operatorname{Parf}(S)$ to $\mathbb{Z}_S$, which we shall again call rank and denote by rg.

Proposition 6.12. a) For $L, M \in \operatorname{ob} \mathrm{D}^-(X)_{\mathrm{parf}}$, with $X \in \operatorname{ob} S$, one has

$$\operatorname{rg}(L \overset{\mathrm{L}}{\otimes} M) = \operatorname{rg}(L)\ \operatorname{rg}(M).$$

b) Let

$$u : (S', A') \longrightarrow (S, A)$$

be a morphism of locally ringed topoi. For $M \in \operatorname{ob} \mathrm{D}^-(S)_{\mathrm{parf}}$, one has

$$\operatorname{rg}(\mathrm{L}u^*(M)) = u^*(\operatorname{rg}(M)).$$

In other words, the rank homomorphism

$$\operatorname{rg} : k(\mathrm{D}^-(S)_{\mathrm{parf}}) \longrightarrow \mathbb{Z}_S$$

is a homomorphism of presheaves of rings, compatible with inverse images.

Proof. It is enough to show that the homomorphism induced by rank on the sheaf associated to $k(\mathrm{D}^-(S)_{\mathrm{Parf}})$ is a homomorphism of sheaves of rings compatible with inverse images. By (6.9), one may replace $k(\mathrm{D}^-(S)_{\mathrm{Parf}})$ by $k(\mathcal{C}_1)$. We are thus reduced to verifying a) and b) for free modules of finite type, which is trivial.

6.13. With (S, A) still denoting a locally ringed topos, let $X \in \operatorname{ob} S$ and $n \in H^0(X, \mathbb{Z}_S)$. We define an object of $\operatorname{Parf}(X)$, denoted A_X^n, as follows. If n is constant of value an integer $n \geq 0$ (respectively $n < 0$), put $A_X^n = A_X^{\oplus n}$ (respectively $A_X^n = A_X^{-n}[1]$). In the general case, decompose X into disjoint pieces X_i on which $n|X_i$ is constant, and define A_X^n as the unique object of $\operatorname{Parf}(X)$ inducing $A_{X_i}^{n|X_i}$ on each X_i. More generally, for $L \in \operatorname{ob} \operatorname{Parf}(X)$, one may define L^n by putting $L^n = A_X^n \otimes_A L$.

The map

$$i_X : H^0(X, \mathbb{Z}_S) \longrightarrow k(\operatorname{Parf}(X)), \qquad i_X(n) = \operatorname{cl}(A_X^n),$$

is a homomorphism of rings, with $i_X(1) = 1$, and defines, as X varies, a homomorphism of presheaves of rings

$$i : \mathbb{Z}_S \longrightarrow k(\operatorname{Parf}(S)).$$

Proposition 6.14. Under the hypotheses of (6.13), one has

$$\mathrm{rg} \circ i = \mathrm{Id}(\mathbb{Z}_S).$$

In other words, $k(\mathrm{Parf}(S))$, considered as a presheaf of $\mathbb{Z}_S$-algebras by means of i, is augmented toward $\mathbb{Z}_S$ by the rank. Moreover, the rank

$$\mathrm{rg} : k(\mathrm{Parf}(S)) \longrightarrow \mathbb{Z}_S$$

defines an isomorphism on the associated sheaves.

Proof. The first assertion follows trivially from the relations

$$\mathrm{cl}(L[1]) = -\mathrm{cl}(L), \qquad \mathrm{cl}(L^n) = n\,\mathrm{cl}(L), \qquad L \in \mathrm{ob}\,\mathrm{Parf}(S).$$

Let us prove the second. First observe that i factors in the evident way through $k(\mathcal{C}_1)$. Since $\mathrm{rg} \circ i$ is the identity, we are reduced, by (6.9), to proving that the homomorphism

$$i \circ \mathrm{rg} : k(\mathcal{C}_1) \longrightarrow k(\mathcal{C}_1)$$

induces an isomorphism on the associated sheaves; equivalently, for $L \in \mathrm{ob}\,\mathcal{C}_1$, that $i(\mathrm{rg}(L))$ is locally isomorphic to L. This is immediate.

One deduces, by (6.6 b):

Corollary 6.15. Under the hypotheses of (6.13), for every abelian sheaf F on S, the group of S-additive functions from $\mathrm{Parf}(S)$ to F is canonically identified with $H^0(S, F)$, where S is the final object of S. The rank function corresponds, for $F = \mathbb{Z}_S$, to the unit section of $\mathbb{Z}_S$.

7. Duality of perfect complexes

7.0. In this section, (S, A) denotes a topos ringed in commutative rings, and S also denotes the final object of S. We propose to generalize to perfect complexes the duality notions that are well known for locally free sheaves of finite type.

Proposition 7.1. Let $E \in \mathrm{ob}\,\mathrm{D}^-(S)_{\mathrm{Parf}}$ and $F \in \mathrm{ob}\,\mathrm{D}^+(S)$.

a) If F has locally bounded cohomology, then so does $\mathrm{RHom}(E, F)$. If F is pseudo-coherent (respectively locally of finite Tor-dimension, respectively perfect), then the same is true of $\mathrm{RHom}(E, F)$.

b) Suppose, moreover, that E is of finite Tor-dimension, a condition satisfied if S is of finite type. Then, if F has bounded cohomology (respectively finite Tor-dimension), the same is true of $\mathrm{RHom}(E, F)$. More precisely, let a, b, m, n be integers such that

$$\mathrm{tor.amp}(E) \subset [a, b]$$

(or, equivalently by (5.8), $\mathrm{parf.amp}(E) \subset [a, b]$), and such that $\mathrm{H}^i(F) = 0$ for $i \notin [m, n]$ (respectively $\mathrm{tor.amp}(F) \subset [m, n]$). Then

$$\mathrm{H}^i(\mathrm{RHom}(E, F)) = 0 \quad (i \notin [m - b, n - a]),$$

respectively

$$\mathrm{tor.amp}(\mathrm{RHom}(E, F)) \subset [m - b, n - a].$$

Proof. Assertion a) is local, so we may suppose E strictly perfect, and then conclude by devissage on E, reducing to $E = A$. For assertion b), we may suppose E strictly perfect with $E^i = 0$ for

$i \notin [a,b]$, and $F^i = 0$ for $i \notin [m,n]$ (respectively F^i flat for every i and $F^i = 0$ for $i \notin [m,n]$). It is then enough to apply the following lemma.

Lemma 7.1.1. Let $E \in \mathrm{ob}\,\mathrm{D}^-(S)$ and $F \in \mathrm{ob}\,\mathrm{D}^+(S)$. If E is strictly pseudo-coherent, that is, in the sense of (2.1), with components direct factors of free finite-type modules, then the canonical arrow of $\mathrm{D}^+(S)$

$$\mathrm{Hom}^\bullet(E,F) \longrightarrow \mathrm{RHom}(E,F)$$

is an isomorphism.

Proof. The spectral sequence

$$E_2^{p0} = \mathrm{H}^p(\mathrm{Hom}^\bullet(E,F)) \Longrightarrow \mathrm{Ext}^p(E,F)$$

where $\mathrm{Ext}^q(E^i,F^j) = 0$ for every $q > 0$ by (1.3.1), degenerates. One obtains isomorphisms

$$E_2^{p0} = \mathrm{H}^p(\mathrm{Hom}^\bullet(E,F)) \xrightarrow{\sim} \mathrm{Ext}^p(E,F) = \mathrm{H}^p(\mathrm{RHom}(E,F)),$$

which prove the assertion.

Proposition 7.1.2. Let

$$f : (S',A') \longrightarrow (S,A)$$

be a morphism of ringed topoi. Let $E \in \mathrm{ob}\,\mathrm{D}^-(S)$ and $F \in \mathrm{ob}\,\mathrm{D}^b(S)$ be such that $\mathrm{RHom}(E,F) \in \mathrm{ob}\,\mathrm{D}^b(S)$ and $\mathrm{L}f^*(F) \in \mathrm{ob}\,\mathrm{D}^b(S')$. There is a functorial canonical arrow

$$\mathrm{L}f^*\mathrm{RHom}(E,F) \longrightarrow \mathrm{RHom}(\mathrm{L}f^*E, \mathrm{L}f^*F).$$

This is an isomorphism if E is perfect.

Proof. By the adjunction of $\mathrm{L}f^*$ and $\mathrm{R}f_*$, it is enough to define an arrow

$$\mathrm{RHom}(E,F) \longrightarrow \mathrm{R}f_*\mathrm{RHom}(\mathrm{L}f^*E, \mathrm{L}f^*F).$$

For this we use the adjunction arrow $F \to \mathrm{R}f_*\mathrm{L}f^*F$ and the duality isomorphism

$$\mathrm{R}f_*\mathrm{RHom}(\mathrm{L}f^*E, \mathrm{L}f^*F) \xrightarrow{\sim} \mathrm{RHom}(E, \mathrm{R}f_*\mathrm{L}f^*F).$$

To see that the arrow of (7.1.2) is an isomorphism for E perfect, one reduces trivially, by localization and devissage, to the case $E = A$, where it is a tautology.

Proposition 7.2. There exists (cf. SGA 5 I 1.6), for $E \in \mathrm{ob}\,\mathrm{D}(S)$ and $F \in \mathrm{ob}\,\mathrm{D}^+(S)$, a functorial canonical arrow

$$E \longrightarrow \mathrm{RHom}(\mathrm{RHom}(E,F),F).$$

This is an isomorphism if $E \in \mathrm{ob}\,\mathrm{D}(S)_{\mathrm{Parf}}$ and $F = A$.

Proof. Define the arrow by resolving F injectively and using the canonical arrow in $\mathrm{K}(S)$

$$E \longrightarrow \mathrm{Hom}^\bullet(\mathrm{Hom}^\bullet(E,F),F).$$

To see that the arrow in question is an isomorphism if E is perfect and $F = A$, one reduces, by localization and devissage, to $E = A$, where it is evident.

Definition 7.3. Let $E \in \mathrm{ob}\,\mathrm{D}(S)$. We shall put

$$\mathrm{RHom}(E,A) = E^\vee,$$

and we shall say that $E^\vee$ is the dual of E.

By (7.1) and (7.2), if $E \in \mathrm{ob}\,\mathrm{D}(S)$ is perfect (respectively perfect and of finite Tor-dimension), then so is $E^\vee$, and the canonical arrow $E \to E^{\vee\vee}$ is an isomorphism. In other words, the functor

$\mathrm{RHom}(\,\cdot\,, A)$ defines an anti-auto-equivalence of the category $\mathrm{D}(S)_{\mathrm{Parf}}$ (respectively $\mathrm{D}(S)_{\mathrm{parf}}$, cf. (5.8.4 b)) with itself.

Lemma 7.4 (Cartan isomorphism) (cf. ([H] II 5.15)). For $E \in \mathrm{ob}\,\mathrm{D}(S)$, $F \in \mathrm{ob}\,\mathrm{D}^-(S)$, and $G \in \mathrm{ob}\,\mathrm{D}^+(S)$, there are functorial canonical isomorphisms

$$\begin{aligned}\mathrm{RHom}(E \overset{\mathrm{L}}{\otimes} F, G) &\xrightarrow{\sim} \mathrm{RHom}(E, \mathrm{RHom}(F, G)),\\ \mathrm{RHom}(E \otimes F, G) &\xrightarrow{\sim} \mathrm{RHom}(E, \mathrm{RHom}(F, G)),\\ \mathrm{Hom}(E \otimes F, G) &\xrightarrow{\sim} \mathrm{Hom}(E, \mathrm{RHom}(F, G)).\end{aligned}$$

Proof. This is standard: resolve G injectively and F flatly.

Lemma 7.5. For $E \in \mathrm{ob}\,\mathrm{D}^-(S)$ and $F \in \mathrm{ob}\,\mathrm{D}^+(S)$, there is a functorial canonical homomorphism

$$E \overset{\mathrm{L}}{\otimes} \mathrm{RHom}(E, F) \longrightarrow F.$$

Proposition 7.6 (cf. ([H] II 5.13)). Let $E \in \mathrm{ob}\,\mathrm{D}(S)$, $F \in \mathrm{ob}\,\mathrm{D}^+(S)$, and $G \in \mathrm{ob}\,\mathrm{D}^+(S)$. Under either of the following hypotheses:

(i) G is of finite Tor-dimension;

(ii) $E \in \mathrm{ob}\,\mathrm{D}^-(S)$, F is of finite Tor-dimension, and $G \in \mathrm{ob}\,\mathrm{D}^b(S)$,

there is a functorial canonical homomorphism

$$\mathrm{RHom}(E, F) \overset{\mathrm{L}}{\otimes} G \longrightarrow \mathrm{RHom}(E, F \overset{\mathrm{L}}{\otimes} G).$$

This is an isomorphism when E is perfect.

Proof. Let us define the arrow. Under hypothesis (i), it is enough to resolve F injectively and G flatly. Under hypothesis (ii), by (7.4) it is equivalent to define an arrow

$$E \overset{\mathrm{L}}{\otimes} \mathrm{RHom}(E, F) \overset{\mathrm{L}}{\otimes} G \longrightarrow F \overset{\mathrm{L}}{\otimes} G.$$

Apply the functor $- \otimes^{\mathrm{L}} G$ to the arrow of (7.5).

To see that the arrow is an isomorphism when E is perfect, use the standard method (cf. the proof of (7.2)): reduce, by localization and devissage, to the case $E = A$.

Corollary 7.7. There exists, for $E \in \mathrm{ob}\,\mathrm{D}(S)_{\mathrm{Parf}}$ and $F \in \mathrm{ob}\,\mathrm{D}^+(S)$, a functorial isomorphism

$$E^\vee \overset{\mathrm{L}}{\otimes} F \xrightarrow{\sim} \mathrm{RHom}(E, F),$$

with the notation of (7.3).

Proof. Apply (7.6), with F and G replaced respectively by A and F, and use the fact (7.1) that $E^\vee \in \mathrm{ob}\,\mathrm{D}(S)_{\mathrm{Parf}}$.

Corollary 7.8. Let $E, F \in \mathrm{ob}\,\mathrm{D}(S)_{\mathrm{Parf}}$. There is a natural arrow

$$\mathrm{RHom}(E, F) \overset{\mathrm{L}}{\otimes} \mathrm{RHom}(F, E) \longrightarrow A,$$

which is a "perfect duality," that is, modulo (7.4), it identifies each of the complexes $\mathrm{RHom}(E, F)$ and $\mathrm{RHom}(F, E)$ with the dual of the other, in the sense of (7.3).

Proof. By (7.5), one has natural pairings $E^\vee \otimes^{\mathrm{L}} E \to A$ and $F^\vee \otimes^{\mathrm{L}} F \to A$. Hence, by tensor product, one obtains a natural pairing

$$E^\vee \overset{\mathrm{L}}{\otimes} F \overset{\mathrm{L}}{\otimes} F^\vee \overset{\mathrm{L}}{\otimes} E \longrightarrow A,$$

which, in view of (7.7), gives the announced pairing on the RHom's. Let us show that it is a perfect duality. There are canonical isomorphisms

$$\begin{aligned} \mathrm{RHom}(F^\vee \overset{\mathrm{L}}{\otimes} E, A) &\xrightarrow{\sim} \mathrm{RHom}(F^\vee, E^\vee) && (7.4)\\ &\xrightarrow{\sim} F^{\vee\vee} \overset{\mathrm{L}}{\otimes} E^\vee && (7.6)\\ &\xrightarrow{\sim} F \overset{\mathrm{L}}{\otimes} E^\vee && (7.2). \end{aligned}$$

Thus, up to a compatibility verification, the result follows. One could also localize and devissage to reduce to $E = F = A$.

Exercise 7.9. Let $E, F \in \mathrm{ob}\, \mathrm{D}(S)_{\mathrm{Parf}}$. Show that there is a canonical isomorphism

$$E^\vee \overset{\mathrm{L}}{\otimes} F^\vee \xrightarrow{\sim} (E \overset{\mathrm{L}}{\otimes} F)^\vee.$$

8. Traces and cup-products

8.0. In this section we generalize to perfect complexes the notion of the trace of an endomorphism of a projective module of finite type (see SGA 5 III for applications). The hypotheses and notation are those of (7.0).

8.1. Let $E \in \mathrm{ob}\, \mathrm{D}(S)_{\mathrm{parf}}$ (5.8.4 b). There is a natural arrow

$$\tau : \mathrm{RHom}(E, E) \longrightarrow A,$$

obtained by composing the inverse of the isomorphism (7.7)

$$\mathrm{RHom}(E, E) \xrightarrow{\sim} E^\vee \overset{\mathrm{L}}{\otimes} E$$

with the canonical arrow (7.5) $E^\vee \otimes^{\mathrm{L}} E \to A$.

Let $U \in \mathrm{ob}\, S$. Applying to τ the functor $H^0(U, \cdot)$, and using the fact that $H^0(U, \mathrm{RHom}(E, E))$ identifies with $\mathrm{Hom}_{\mathrm{D}(U)}(E|U, E|U)$, one obtains a homomorphism of $H^0(U, A)$-modules

$$\mathrm{Tr}_{E|U} : \mathrm{Hom}_{\mathrm{D}(U)}(E|U, E|U) \longrightarrow H^0(U, A),$$

which we shall call the trace homomorphism. The finite Tor-dimension hypothesis on E is in fact superfluous for the definition of $\mathrm{Tr}_{E|U}$; see (8.5).

Before going further, we give some properties of the trace that follow immediately from the definition.

8.1.1. If $E = A$, then

$$\mathrm{Tr}_{A|U} : \mathrm{Hom}(A|U, A|U) \longrightarrow H^0(U, A)$$

is just the well-known isomorphism. If E is a direct factor of a free module of finite type, an endomorphism of E over U is locally defined by

$$e \longmapsto \sum_i \langle e, x_i^\vee \rangle x_i,$$

where x_i (respectively $x_i^\vee$) is a local section of E (respectively $E^\vee$); the corresponding trace is $\sum_i \langle x_i, x_i^\vee \rangle$. It follows easily that, if E and F are direct factors of free modules of finite type, and if

$$u : (E+F)|U \longrightarrow (E+F)|U$$

is defined by a matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$, then

$$\mathrm{Tr}_{(E+F)|U}(u) = \mathrm{Tr}_{E|U}(a) + \mathrm{Tr}_{F|U}(d).$$

8.1.2. Let E be a strictly perfect complex, let $U \in \mathrm{ob}\, S$, and let

$$u : E|U \longrightarrow E|U$$

be a homomorphism of complexes, with components $u^i : E^i|U \to E^i|U$. Then

$$\mathrm{Tr}_{E|U}(u) = \sum_i (-1)^i \mathrm{Tr}_{E^i|U}(u^i).$$

Indeed, the question being local, one may suppose that u is defined by a section of $H^0(E^\vee \otimes E)$, and even that this section is of the form

$$\sum_{i,j} x_{ij}^\vee \otimes x_{ij},$$

where x_{ij} (respectively $x_{ij}^\vee$) is a section of E^i (respectively $E^{i\vee}$). Making explicit the arrow (7.5) $E^\vee \otimes^{\mathrm{L}} E \to A$, one finds

$$\mathrm{Tr}_{E|U}(u) = \sum_{i,j} (-1)^i \langle x_{ij}, x_{ij}^\vee \rangle = \sum_i (-1)^i \mathrm{Tr}_{E^i|U}(u^i).$$

8.2. Let $E, F \in \mathrm{ob}\, \mathrm{D}(S)_{\mathrm{Parf}}$. We have seen in (7.8) that there is a canonical homomorphism

$$\chi : \mathrm{RHom}(E,F) \overset{\mathrm{L}}{\otimes} \mathrm{RHom}(F,E) \longrightarrow A.$$

Let $U \in \mathrm{ob}\, S$, and let

$$u \in H^0(U, \mathrm{RHom}(E,F)), \qquad v \in H^0(U, \mathrm{RHom}(F,E)).$$

One may interpret u (respectively v) as a homomorphism, in $\mathrm{D}(U)$, from $A|U$ to $\mathrm{RHom}(E,F)|U$ (respectively $\mathrm{RHom}(F,E)|U$), and form

$$u \overset{\mathrm{L}}{\otimes} v : A|U \longrightarrow (\mathrm{RHom}(E,F) \overset{\mathrm{L}}{\otimes} \mathrm{RHom}(F,E))|U.$$

The map $(u,v) \mapsto \langle u, v \rangle = \chi \circ (u \otimes^{\mathrm{L}} v)$ defines an $H^0(U,A)$-bilinear pairing

$$\mathrm{Hom}_{\mathrm{D}(U)}(E|U, F|U) \otimes_{H^0(U,A)} \mathrm{Hom}_{\mathrm{D}(U)}(F|U, E|U) \longrightarrow H^0(U,A),$$

which we shall call the cup-product. The same comment as for the definition of $\mathrm{Tr}_{E|U}$ applies here.

The relation between trace and cup-product is expressed in the following proposition.

Proposition 8.3. In the situation of (8.2), for $u \in \mathrm{Hom}(E|U, F|U)$ and $v \in \mathrm{Hom}(F|U, E|U)$, one has

$$\mathrm{Tr}_{E|U}(vu) = \mathrm{Tr}_{F|U}(uv) = \langle u, v \rangle.$$

In particular, if $E = F$, then

$$\mathrm{Tr}_{E|U}(u) = \langle u, \mathrm{Id}\rangle = \langle \mathrm{Id}, u\rangle.$$

Proof. For simplicity we suppose $U = S$. We therefore have two arrows

$$u : A \longrightarrow E^\vee \overset{\mathrm{L}}{\otimes} F, \qquad v : A \longrightarrow F^\vee \overset{\mathrm{L}}{\otimes} E,$$

and hence

$$u \overset{\mathrm{L}}{\otimes} v : A \longrightarrow E^\vee \overset{\mathrm{L}}{\otimes} F \overset{\mathrm{L}}{\otimes} F^\vee \overset{\mathrm{L}}{\otimes} E.$$

On the other hand, we have seen that $vu : A \to E^\vee \otimes^{\mathrm{L}} E$ and $uv : A \to F^\vee \otimes^{\mathrm{L}} F$. The proposition follows from the commutativity of the following diagrams, whose verification is purely mechanical:

$$\begin{array}{ccc} A & \xrightarrow{u \otimes^{\mathrm{L}} v} & E^\vee \otimes^{\mathrm{L}} F \otimes^{\mathrm{L}} F^\vee \otimes^{\mathrm{L}} E \\ & \searrow^{vu} & \downarrow{\scriptstyle \mathrm{Id} \otimes \tau_F} \\ & & E^\vee \otimes^{\mathrm{L}} E \end{array} \qquad \begin{array}{ccc} A & \xrightarrow{u \otimes^{\mathrm{L}} v} & E^\vee \otimes^{\mathrm{L}} F \otimes^{\mathrm{L}} F^\vee \otimes^{\mathrm{L}} E \\ & \searrow^{uv} & \downarrow{\scriptstyle \tau_E \otimes \mathrm{Id}} \\ & & F^\vee \otimes^{\mathrm{L}} F \end{array}$$

$$\begin{array}{ccc} E^\vee \otimes^{\mathrm{L}} F \otimes^{\mathrm{L}} F^\vee \otimes^{\mathrm{L}} E & \xrightarrow{\mathrm{Id} \otimes \tau_E} & F^\vee \otimes^{\mathrm{L}} F \\ \downarrow{\scriptstyle \mathrm{Id} \otimes \tau_F} & & \downarrow{\scriptstyle \tau_F} \\ E^\vee \otimes^{\mathrm{L}} E & \xrightarrow[\tau_E]{} & A. \end{array}$$

Corollary 8.4. Let E, F, U be as in (8.2), let $u \in \mathrm{Hom}(E|U, E|U)$, and let $s : E|U \to F|U$ be an isomorphism. Then $sus^{-1} \in \mathrm{Hom}(F|U, F|U)$, and

$$\mathrm{Tr}_{F|U}(sus^{-1}) = \mathrm{Tr}_{E|U}(u).$$

Proof. Immediate.

Remark 8.5. If $\mathcal{C}$ is a fibered S-category, denote by $\mathcal{E}(\mathcal{C})$ the fibered S-category whose fiber over $U \in \mathrm{ob}\, S$ is the category whose objects are pairs (L, u), with $L \in \mathrm{ob}\, \mathcal{C}_U$ and $u \in \mathrm{End}_S(L)$, and whose arrows from (L, u) to (M, v) are the arrows $f : L \to M$ such that $fu = vf$. By (8.4) one may regard the trace homomorphism as an S-functor from $\mathcal{E}(\mathrm{D}(S)_{\mathrm{Parf}})^{\mathrm{is}}$ to $\mathcal{A}$, where the exponent is means that only isomorphisms are considered, and where $\mathcal{A}$ is the S-category with discrete fibers defined by A (cf. (6.6 a)). Since every perfect complex is locally of finite Tor-dimension, the forgetful S-functor

$$\mathcal{E}(\mathrm{D}(S)_{\mathrm{Parf}})^{\mathrm{is}} \longrightarrow \mathcal{E}(\mathrm{D}(S)_{\mathrm{parf}})^{\mathrm{is}}$$

induces an isomorphism on the associated stacks. Consequently, the trace homomorphism extends uniquely to an S-functor from $\mathcal{E}(\mathrm{D}(S)_{\mathrm{Parf}})^{\mathrm{is}}$ to $\mathcal{A}$.

For $E \in \mathrm{ob}\, \mathrm{Parf}(U)$, $U \in \mathrm{ob}\, S$, we again write

$$\mathrm{Tr}_E : \mathrm{Hom}(E, E) \longrightarrow H^0(U, A)$$

for the corresponding homomorphism, which is an $H^0(U, A)$-module homomorphism. One sees in the same way that the definition of the cup-product (8.2), as well as assertions (8.3) and (8.4), generalize to perfect complexes, not necessarily of finite Tor-dimension.

Proposition 8.6. Let $U \in \operatorname{ob} S$, let $E, F \in \operatorname{Parf}(U)$, and let $u \in \operatorname{Hom}(E,E)$, $v \in \operatorname{Hom}(F,F)$; hence $u \otimes^{\mathrm{L}} v \in \operatorname{Hom}(E \otimes^{\mathrm{L}} F, E \otimes^{\mathrm{L}} F)$. Then

$$\operatorname{Tr}_{E \otimes^{\mathrm{L}} F}(u \overset{\mathrm{L}}{\otimes} v) = \operatorname{Tr}_E(u)\ \operatorname{Tr}_F(v).$$

Proof. The question being local, by (8.4) and (4.10) one may suppose that u and v are arrows of $K^b(\mathcal{C}_0)$. Using (8.1.2), one is reduced to the case where u and v are arrows of $\mathcal{C}_0$. One finishes by (8.1.1).

Exposé II. Existence of global resolutions

by L. Illusie

1. General globalization criteria

1.0

In this section we are given a site S, a flat abelian S-category $\mathcal{C}$ (I 1.1), and a strictly full additive sub-S-category $\mathcal{C}_0$ (I 1.1). We assume that $\mathcal{C}_0$ is locally quasi-liftable in $\mathcal{C}$ (I 1.2) and locally quasi-stable under kernels of epimorphisms (I 1.2).

Proposition 1.1. Let $S \in \operatorname{ob}(S)$, and suppose that:

(i) $\mathcal{C}_{0S}$ is quasi-liftable in $\mathcal{C}_S$ (I 1.2), where $\mathcal{C}_S$ is regarded as a category fibered over a punctual site;

(ii) every object of $\mathcal{C}_S$ which is of finite $\mathcal{C}_0$-type (I 1.2), respectively of finite $\mathcal{C}_0$-presentation (I 2.8), is of finite $\mathcal{C}_{0S}$-type.

Then:

a) $\mathcal{C}_{0S}$ is quasi-stable under kernels of epimorphisms (I 1.2), where $\mathcal{C}_{0S}$ is regarded as a category fibered over a punctual site.

b) Let $E \in \operatorname{ob} \mathrm{D}^-(\mathcal{C}_S)$ and $n \in \mathbb{Z}$. If E is n-$\mathcal{C}_0$-pseudo-coherent (I 2.2), then E is n-$\mathcal{C}_{0S}$-pseudo-coherent, respectively $(n+1)$-$\mathcal{C}_{0S}$-pseudo-coherent. In other words,

$$\mathrm{D}^-(\mathcal{C}_S)_{n-\mathcal{C}_0\text{-coh}} = \mathrm{D}^-(\mathcal{C}_S)_{n-\mathcal{C}_{0S}\text{-coh}},$$

and, respectively,

$$\mathrm{D}^-(\mathcal{C}_S)_{n-\mathcal{C}_0\text{-coh}} \subset \mathrm{D}^-(\mathcal{C}_S)_{(n+1)-\mathcal{C}_{0S}\text{-coh}} \subset \mathrm{D}^-(\mathcal{C}_S)_{(n+1)-\mathcal{C}_0\text{-coh}},$$

inclusions of strictly full subcategories of $\mathrm{D}(\mathcal{C}_S)$, the inclusion on the right being trivial.

c) For an object $E \in \operatorname{ob} \mathrm{D}(\mathcal{C}_S)$ to be pseudo-coherent relative to $\mathcal{C}_0$ (I 2.3), it is necessary and sufficient that it be pseudo-coherent relative to $\mathcal{C}_{0S}$; equivalently,

$$\mathrm{D}^-(\mathcal{C}_S)_{\mathcal{C}_0\text{-coh}} = \mathrm{D}^-(\mathcal{C}_S)_{\mathcal{C}_{0S}\text{-coh}}.$$

Moreover, the canonical functor

$$\mathrm{K}^-(\mathcal{C}_{0S})/\mathrm{K}^{-,\delta}(\mathcal{C}_{0S}) \longrightarrow \mathrm{D}(\mathcal{C}_S),$$

where $\mathrm{K}^{-,\delta}(\mathcal{C}_{0S})$ denotes the thick subcategory of $\mathrm{K}^-(\mathcal{C}_{0S})$ formed by acyclic complexes, is fully faithful and has as essential image $\mathrm{D}^-(\mathcal{C}_S)_{\mathcal{C}_0\text{-coh}}$. If $\mathcal{C}_{0S}$ is liftable in $\mathcal{C}_S$ (I 1.2), that is, if the objects of $\mathcal{C}_{0S}$ are projective, then $\mathrm{K}^{-,\delta}(\mathcal{C}_{0S})$ is reduced to zero objects, and consequently the functor

$$\mathrm{K}^-(\mathcal{C}_{0S}) \longrightarrow \mathrm{D}(\mathcal{C}_S)$$

is fully faithful and has essential image $\mathrm{D}^-(\mathcal{C}_S)_{\mathcal{C}_0\text{-coh}}$.

Proof. a) Let

$$0 \longrightarrow L \longrightarrow L^0 \longrightarrow \cdots \longrightarrow L^m \longrightarrow 0$$

be an exact sequence in $\mathcal{C}_S$, with $L^i \in \operatorname{ob} \mathcal{C}_{0S}$ for all i. It is enough to prove that L is of finite $\mathcal{C}_{0S}$-type. By (I 2.2), L is $\mathcal{C}_0$-pseudo-coherent, hence, by (I 2.9), of finite $\mathcal{C}_0$-presentation; the assertion follows from (ii).

b) We prove by descending induction on i that E is i-$\mathcal{C}_{0S}$-pseudo-coherent for $i \geq n$, respectively for $i \geq n+1$. One may already suppose that E is strictly $(n+1)$-$\mathcal{C}_{0S}$-pseudo-coherent, respectively strictly $(n+2)$-$\mathcal{C}_{0S}$-pseudo-coherent (I 2.1); the point is then to prove that E is n-$\mathcal{C}_{0S}$-pseudo-coherent, respectively $(n+1)$-$\mathcal{C}_{0S}$-pseudo-coherent. Thus there is an exact sequence

$$0 \longrightarrow E' \longrightarrow E \longrightarrow E'' \longrightarrow 0,$$

where E' is strictly $\mathcal{C}_{0S}$-perfect (I 2.1) and $E''^i = 0$ for $i > n$, respectively for $i > n+1$. Replacing E by E'', one may therefore suppose (I 2.6) that $E^i = 0$ for $i > n$, respectively for $i > n+1$. Then, by (I 2.10 a)), $H^n(E)$, respectively $H^{n+1}(E)$, is of finite $\mathcal{C}_0$-type, respectively of finite $\mathcal{C}_0$-presentation. Hence, by (ii), $H^n(E)$, respectively $H^{n+1}(E)$, is of finite $\mathcal{C}_{0S}$-type. Applying (I 2.10 b)) again, one obtains that E is n-$\mathcal{C}_{0S}$-pseudo-coherent, respectively $(n+1)$-$\mathcal{C}_{0S}$-pseudo-coherent. The hypothesis (i) and part a) have been used implicitly in the references to (I 2.6 and 2.10).

c) The first assertion follows from b), the second from (I 2.7), and the last is evident.

Proposition 1.2. Suppose that $\mathcal{C}_0$ is locally liftable in $\mathcal{C}$ (I 1.2) and locally stable under kernels of epimorphisms (I 1.2), and make the hypotheses (1.1 (i) and (ii), respectively). Let $\mathcal{C}_{1S}$ denote the strictly full subcategory of $\mathcal{C}_S$ formed by the objects which are locally in $\mathcal{C}_0$. Then:

a) $\mathcal{C}_{1S}$ is stable under kernels of epimorphisms (I 1.2) and is quasi-liftable in $\mathcal{C}_S$ (I 1.2), as a category fibered over a punctual site.

b) Let $E \in \operatorname{ob} \mathrm{D}(\mathcal{C}_S)$ and let $[m,n]$ be an interval of $\mathbb{Z}$. For E to have $\mathcal{C}_0$-perfect amplitude contained in $[m,n]$, it is necessary and sufficient that E be isomorphic, in $\mathrm{D}(\mathcal{C}_S)$, to a complex F such that $F^i = 0$ for $i \notin [m,n]$, $F^i \in \operatorname{ob} \mathcal{C}_{0S}$ for $i > m$, and $F^m \in \operatorname{ob} \mathcal{C}_{1S}$.

c) The canonical functor
$$\mathrm{K}^b(\mathcal{C}_{1S})/\mathrm{K}^{b,\delta}(\mathcal{C}_{1S}) \longrightarrow \mathrm{D}(\mathcal{C}_S)$$
is fully faithful and has as essential image the full subcategory of $\mathrm{D}(\mathcal{C}_S)$ formed by complexes of finite $\mathcal{C}_0$-perfect amplitude.

d) If $\mathcal{C}_{1S}$ is not merely quasi-liftable but liftable in $\mathcal{C}_S$, one may replace, in b), the expression "E is isomorphic to F in $\mathrm{D}(\mathcal{C}_S)$" by "there exists a quasi-isomorphism $F \to E$"; and, in c), $\mathrm{K}^{b,\delta}(\mathcal{C}_{1S})$ is reduced to zero objects.

Proof. a) It is clear that $\mathcal{C}_{1S}$ is stable under kernels of epimorphisms. On the other hand, the objects of $\mathcal{C}_{1S}$ are $\mathcal{C}_0$-pseudo-coherent, hence $\mathcal{C}_{0S}$-pseudo-coherent by (1.1 c)); the second assertion follows from (I 2.14), taking S to be the punctual site.

b) It suffices to prove necessity. By (1.1 c)), E is already $\mathcal{C}_{0S}$-pseudo-coherent. Since E is acyclic in degree $> n$, one may, after replacing E by an isomorphic complex in $\mathrm{D}(\mathcal{C}_S)$, suppose (I 2.10) that E is strictly $(m+1)$-$\mathcal{C}_{0S}$-pseudo-coherent and that $E^i = 0$ for $i > n$. Since E is acyclic in degree $< m$, one may also replace E by its truncation
$$0 \longrightarrow E^m/B^m \longrightarrow E^{m+1} \longrightarrow \cdots \longrightarrow E^n \longrightarrow 0,$$
so that $E^i = 0$ for $i < m$. Then, by (I 4.16), E^m is locally an object of $\mathcal{C}_0$, and therefore an object of $\mathcal{C}_{1S}$.

c) In view of (1.2 a)), the assertion follows from (1.2 b)) and (I 4.12.2). d) The fact that $\mathrm{K}^{b,\delta}(\mathcal{C}_{1S})$ is reduced to zero objects is evident. The other assertion follows from (I 4.6), applied over the punctual site.

2. Application to certain categories of modules

2.0. Notation

Let (S, A) be a ringed topos. For $U \in \operatorname{ob} S$, write $\mathrm{Mod}(U)$ for the category of left A_U-modules, and $\mathrm{Lib}(U)$, respectively $\mathrm{Loclib}(U)$, for the full subcategory of $\mathrm{Mod}(U)$ formed by free A_U-modules, respectively modules locally direct factors of free modules, of finite type.

2.1. Lifting lemmas

Lemma 2.1.1 (cf. EGA 0_{I}, 5.2.3). Let (S, A) be a ringed topos, and let $S \in \operatorname{ob} S$. Suppose that S is quasi-compact, that is, every covering family $(S_i \to S)$ is dominated by a finite covering family.

a) Let F be a left A_S-module which is the filtered inductive limit, over a filtered category Λ, of A_S-modules F_λ, and let
$$u = \varinjlim u_\lambda : F \longrightarrow G$$
be an epimorphism, where G is an A_S-module of finite type. Then there exists $\lambda \in \Lambda$ such that u_λ is an epimorphism.

b) Let F be a left A_S-module generated by its sections, that is, such that there exists an epimorphism $A_S^{(I)} \to F$ for a suitable set of indices I. If F is of finite type, then there exists an epimorphism $A_S^p \to F$ for some $p \in \mathbb{N}$.

The proof of a) is analogous to the proof of the cited result and is left to the reader; b) follows immediately from a).

Lemma 2.1.2. Let (S, A) be a ringed topos, let $\mathcal{C}$ be the S-category fibered in left A-modules, let $\mathcal{C}_0$ be the fibered subcategory of free A-modules of finite type (I 1.3 d)), let $S \in \operatorname{ob} S$, and let $\mathcal{C}'_S$ be a strictly full additive subcategory of $\mathcal{C}_S$ containing $\mathcal{C}_{0S}$ and stable under kernels, cokernels, and extensions. Suppose that

$$H^1(S, F) = 0 \quad \text{for every } F \in \operatorname{ob} \mathcal{C}'_S.$$

Then:

a) Every exact sequence in $\mathcal{C}_S$

$$0 \longrightarrow E \longrightarrow F \longrightarrow G \longrightarrow 0,$$

such that $\operatorname{Hom}(G, E) \in \operatorname{ob} \mathcal{C}'_S$ and such that G is locally a direct factor of a free module of finite type, is split. The category $\mathcal{C}_{0S}$ is liftable in $\mathcal{C}'_S$ (I 2.2).

b) Let $\operatorname{Mod}(A(S))$ denote the category of $A(S)$-modules. The functor

$$\Gamma_S : \mathcal{C}'_S \longrightarrow \operatorname{Mod}(A(S))$$

is exact. Moreover:

(i) if every object F of $\mathcal{C}'_S$ admits a finite global presentation

$$A_S^q \longrightarrow A_S^p \longrightarrow F \longrightarrow 0,$$

then Γ_S is fully faithful and has as essential image the full subcategory of $\operatorname{Mod}(A(S))$ formed by $A(S)$-modules of finite presentation;

(ii) if $\mathcal{C}'_S$ contains the free A_S-modules, if every object F of $\mathcal{C}'_S$ admits a global presentation

$$A_S^{(J)} \longrightarrow A_S^{(I)} \longrightarrow F \longrightarrow 0,$$

and if Γ_S commutes with filtered inductive limits, then Γ_S is an equivalence of categories.

Proof. a) Since G is locally a direct factor of a free module of finite type, the spectral sequence

$$E_2^{pq} = H^p(S, \mathcal{E}xt^q(G, E)) \Longrightarrow \operatorname{Ext}^{p+q}(G, E)$$

degenerates (I 1.3.1) and gives an isomorphism

$$H^1(S, \operatorname{Hom}(G, E)) \simeq \operatorname{Ext}^1(G, E),$$

whence the first assertion. The second is a particular case, since for $G \in \operatorname{ob} \mathcal{C}_{0S}$ and $E \in \operatorname{ob} \mathcal{C}'_S$ one has $\operatorname{Hom}(G, E) \in \operatorname{ob} \mathcal{C}'_S$.

b) The first assertion is trivial. Let us prove, in case (i) or (ii), the full faithfulness of $\Gamma_S : \mathcal{C}'_S \to \operatorname{Mod}(A(S))$. Let $F, G \in \operatorname{ob} \mathcal{C}'_S$ and let

$$A_S^{(J)} \longrightarrow A_S^{(I)} \longrightarrow F \longrightarrow 0 \qquad (*)$$

be a global presentation of F, with I and J finite in case (i). Applying Γ_S, which is exact on $\mathcal{C}'_S$ and, in case (ii), commutes with filtered inductive limits, one obtains an exact sequence

$$A(S)^{(J)} \longrightarrow A(S)^{(I)} \longrightarrow \Gamma_S(F) \longrightarrow 0. \qquad (**)$$

Applying the left exact functors $\mathrm{Hom}_{\mathcal{C}_S}(-, G)$ and $\mathrm{Hom}_{A(S)}(-, \Gamma_S(G))$ to $(*)$ and $(**)$ gives a commutative diagram with exact rows:

$$\begin{array}{ccccccc} 0 & \longrightarrow & \mathrm{Hom}_{\mathcal{C}_S}(F, G) & \longrightarrow & \mathrm{Hom}_{\mathcal{C}_S}(A_S^{(I)}, G) & \longrightarrow & \mathrm{Hom}_{\mathcal{C}_S}(A_S^{(J)}, G) \\ & & \downarrow & & \downarrow\sim & & \downarrow\sim \\ 0 & \longrightarrow & \mathrm{Hom}_{A(S)}(\Gamma_S F, \Gamma_S G) & \longrightarrow & \mathrm{Hom}_{A(S)}(A(S)^{(I)}, \Gamma_S G) & \longrightarrow & \mathrm{Hom}_{A(S)}(A(S)^{(J)}, \Gamma_S G). \end{array}$$

The two vertical arrows on the right are visibly isomorphisms, hence so is the arrow on the left. The description of the essential image in cases (i) and (ii) is immediate and is left to the reader.

Lemma 2.1.3. Let $\mathcal{A}$ and $\mathcal{B}$ be abelian categories, and let $\varphi : \mathcal{A} \to \mathcal{B}$ be an exact functor.

a) For $M \in \mathrm{ob}\,\mathcal{A}$, the following conditions are equivalent:

   (i) for every $L \in \mathrm{ob}\,\mathcal{A}$, the canonical map induced by φ

   $$\mathrm{Ext}^n_{\mathcal{A}}(L, M) \longrightarrow \mathrm{Ext}^n_{\mathcal{B}}(\varphi L, \varphi M)$$

   is an isomorphism for all n;

   (ii) for every $L \in \mathrm{ob}\,\mathcal{A}$, the canonical map

   $$\mathrm{Hom}_{\mathcal{A}}(L, M) \longrightarrow \mathrm{Hom}_{\mathcal{B}}(\varphi L, \varphi M)$$

   is an isomorphism, and for every $n \geq 1$ and every $x \in \mathrm{Ext}^n_{\mathcal{B}}(\varphi L, \varphi M)$ there exists an epimorphism $L' \to L$ in $\mathcal{A}$ which kills x.

b) The following conditions are equivalent:

   (i) for all $L, M \in \mathrm{ob}\,\mathcal{A}$ and all $n \in \mathbb{Z}$, the canonical map

   $$\mathrm{Ext}^n_{\mathcal{A}}(L, M) \longrightarrow \mathrm{Ext}^n_{\mathcal{B}}(\varphi L, \varphi M)$$

   is an isomorphism;

   (ii) the canonical functor induced by φ

   $$\mathrm{D}^b(\mathcal{A}) \longrightarrow \mathrm{D}^b(\mathcal{B})$$

   is fully faithful and has as essential image the full subcategory of $\mathrm{D}^b(\mathcal{B})$ formed by complexes F such that $H^i(F)$ is in the essential image of φ for every i.

Proof. For (i)⇒(ii) in a), it is enough to show that, if $n \geq 1$, $L \in \mathrm{ob}\,\mathcal{A}$, and $y \in \mathrm{Ext}^n_{\mathcal{A}}(L, M)$, then there exists an epimorphism $L' \to L$ killing y. Using Yoneda's interpretation ([18], III 3.2), y is the class of an exact sequence

$$0 \longrightarrow M \longrightarrow E_{n-1} \longrightarrow \cdots \longrightarrow E_0 \longrightarrow L \longrightarrow 0,$$

and the epimorphism $E_0 \to L$ kills y ([18], III 3.2.5 and 3.2.8). Conversely, put

$$F^n(L) = \mathrm{Ext}^n_{\mathcal{A}}(L, M), \qquad G^n(L) = \mathrm{Ext}^n_{\mathcal{B}}(\varphi L, \varphi M).$$

The effaceability hypothesis says, for $n \geq 1$ and $L \in \mathrm{ob}\,\mathcal{A}$, that

$$G^n(L) = \varinjlim \mathrm{Coker}\, igl(G^{n-1}(L_0) \to G^{n-1}(L_1)),$$

the limit being taken over the exact sequences $L_1 \to L_0 \to L \to 0$. As above, one has the same formula for $F^n(L)$. Since $F^0 \to G^0$ is an isomorphism, induction on n shows that the morphism $F^n \to G^n$ induced by φ is an isomorphism for every n. The equivalence in b) follows by an immediate dévissage, left to the reader.

Remarks 2.1.3.1. There is of course a dual version of a), which we leave to the reader to state. On the other hand, if $\mathcal{A}$ and $\mathcal{B}$ have enough injectives, the conditions (i) and (ii) of b) are equivalent to:

(iii) for $L \in \mathrm{ob}\,\mathrm{D}^-(\mathcal{A})$ and $M \in \mathrm{ob}\,\mathrm{D}^+(\mathcal{A})$, the canonical map

$$\mathrm{RHom}(L, M) \longrightarrow \mathrm{RHom}(\varphi L, \varphi M)$$

is an isomorphism,

as is seen at once by a spectral sequence argument.

2.2. Noetherian schemes and divisorial schemes

Notation 2.2.1. Let S be a scheme. We write $\mathrm{Qcoh}(S)$, respectively $\mathrm{Coh}(S)$, for the abelian category of quasi-coherent, respectively coherent, $\mathcal{O}_S$-modules. Let $[m, n]$ be an interval of $\mathbb{Z}$. We shall say that an object E of $\mathrm{D}(\mathrm{Qcoh}(S))$ is n-pseudo-coherent, respectively pseudo-coherent, respectively of perfect amplitude contained in $[m, n]$, respectively perfect, if it is so relative to the category fibered over the Zariski site of S defined by

$$U \longmapsto \mathrm{Loclib}(U)$$

((I 2.3), (I 4.7), and (2.0)). We denote by $\mathrm{D}^-(\mathrm{Qcoh}(S))_{\mathrm{coh}}$, respectively $\mathrm{D}(\mathrm{Qcoh}(S))_{\mathrm{parf}}$, the full triangulated subcategory of $\mathrm{D}(\mathrm{Qcoh}(S))$ formed by pseudo-coherent, respectively perfect, complexes.

Proposition 2.2.2. Let S be a noetherian scheme. The canonical functor

$$\mathrm{D}^-(\mathrm{Coh}(S)) \longrightarrow \mathrm{D}(\mathrm{Qcoh}(S))$$

is fully faithful and has as essential image $\mathrm{D}^-(\mathrm{Qcoh}(S))_{\mathrm{coh}}$.

Proof. Apply (1.1), taking for the site the Zariski site of S, and for $\mathcal{C}$, respectively $\mathcal{C}_0$, the fibered categories $U \mapsto \mathrm{Qcoh}(U)$, respectively $U \mapsto \mathrm{Coh}(U)$. Since $\mathcal{O}_S$ is coherent, the objects of $\mathcal{C}_0$ are pseudo-coherent (I 3.5); hence an object of $\mathrm{D}(\mathrm{Qcoh}(U))$ is pseudo-coherent, in the sense of (2.2.1), if and only if it is pseudo-coherent relative to $\mathcal{C}_0$ (I 2.14.1). By (1.1 c)), it remains to verify conditions (i) and (ii) of (1.1). For (ii) this is trivial, since a quasi-coherent module which is a quotient of a coherent module is coherent, and coherence is local. For (i), one uses (2.1.1 a)) and the fact that every quasi-coherent $\mathcal{O}_S$-module is a filtered inductive limit of coherent $\mathcal{O}_S$-modules (EGA I 9.4.9).

Granting (3.5) and (3.7), which are independent of the present section, one easily deduces the following.

Corollary 2.2.2.1. Let S be a noetherian scheme, respectively a noetherian scheme of finite dimension. The canonical functor

$$\mathrm{D}^b(\mathrm{Coh}(S)) \longrightarrow \mathrm{D}(S)$$

respectively

$$\mathrm{D}^-(\mathrm{Coh}(S)) \longrightarrow \mathrm{D}(S)$$

is fully faithful and has as essential image $\mathrm{D}^b(S)_{\mathrm{coh}}$, respectively $\mathrm{D}^-(S)_{\mathrm{coh}}$ (I 2.15).

Proposition 2.2.3 (cf. EGA II 4.5.2 and 4.5.5). Let S be a quasi-compact and quasi-separated scheme, and let $(L_i)_{i\in I}$ be a family of invertible sheaves on S. For every $\mathcal{O}_S$-module F and every pair $(i,n) \in I \times \mathbb{Z}$, let $F_{(i,n)}$ denote the sub-$\mathcal{O}_S$-module of $F \otimes L_i^{\otimes n}$ generated by the sections of $F \otimes L_i^{\otimes n}$ over S. The following conditions are equivalent:

(i) the open sets S_f, for $f \in \Gamma(S, L_i^{\otimes n})$, $i \in I$ and $n \in \mathbb{N}$, form a base for the topology of S;

(ii) those of the S_f which are affine cover S;

(iii) for every quasi-coherent $\mathcal{O}_S$-module F of finite type, there exists a finite family (i_α, n_α) with $n_\alpha \geq 0$ and an epimorphism

$$\bigoplus_\alpha L_{i_\alpha}^{\otimes(-n_\alpha)} \longrightarrow F;$$

(iv) for every $F \in \mathrm{ob}\,\mathrm{Qcoh}(S)$, one has

$$F = \sum_{(i,n)\in I\times\mathbb{N}} F_{(i,n)} \otimes L_i^{\otimes(-n)},$$

a sum, not necessarily direct, of sub-sheaves of F;

(v) same condition as (iv), but with F a quasi-coherent ideal of $\mathcal{O}_S$.

Proof. This is a simple paraphrase of the cited passages; we recall the argument briefly for the reader's convenience. For (i)⇒(ii), choose for $x \in S$ an affine open U containing x. An open S_f with $x \in S_f \subset U$, where $f \in \Gamma(S, L_i^{\otimes n})$ and $n \geq 0$, is necessarily affine, by the following lemma.

Lemma 2.2.3.1 (EGA II 5.5.8). Let X be a scheme, L an invertible $\mathcal{O}_X$-module, and $f \in \Gamma(X, L)$. The canonical immersion $X_f \to X$ is affine.

Proof. This is trivial: the question is local on X, so one may suppose X affine and $L \simeq \mathcal{O}_X$.

For (ii)⇒(iii), choose a finite covering of S by affine opens $S_{f_{ij}}$, with $f_{ij} \in \Gamma(S, L_i^{\otimes m_{ij}})$. Replacing the f_{ij} by suitable powers, one may suppose that the m_{ij} with fixed i are all equal to an integer m_i. If F is quasi-coherent of finite type, then, for each i, j, there is an integer $q_i \geq 0$ such that every section of F over $S_{f_{ij}}$ extends to a section of $F \otimes L_i^{\otimes q_i m_i}$ over S. Thus $F \otimes L_i^{\otimes q_i m_i}$ is generated over $S_{f_{ij}}$ by finitely many global sections. Proceeding as in the proof of EGA II 4.5.5, one obtains, for each i, an integer $n_i \geq 0$ such that $F \otimes L_i^{\otimes n_i}$ is generated over the union of the corresponding $S_{f_{ij}}$ by finitely many sections over S. Hence there are integers $r_i \geq 0$ and a morphism

$$L_i^{-n_i r_i} \longrightarrow F$$

which induces an epimorphism over that union; the assertion follows.

For (iii)⇒(iv), since every quasi-coherent sheaf on S is the inductive limit of its quasi-coherent subsheaves of finite type (EGA I 9.4.9 and IV 1.7.7), it is enough to treat the case where F is of finite type. There exist morphisms

$$u_i : L_i^{-n_i r_i} \longrightarrow F$$

whose sum is an epimorphism. But

$$\mathrm{Im}(u_i) = \mathrm{Im}(u_i \otimes \mathrm{Id}(L_i^{n_i})) \otimes L_i^{-n_i},$$

and $\mathrm{Im}(u_i \otimes \mathrm{Id}(L_i^{n_i}))$ is a subsheaf of $F_{(i,n_i)}$, which gives the assertion. The implication (iv)⇒(v) is trivial. Finally, for (v)⇒(i), let $x \in S$, let U be an open containing x, and let F be a quasi-coherent ideal defining $S - U$. By (v), there are $(i,n) \in I \times \mathbb{N}$ and a section f of $F \otimes L_i^{\otimes n}$ over S with $f(x) \neq 0$. Then $x \in S_f \subset U$, proving (i).

Definition 2.2.4. Let S be a quasi-compact and quasi-separated scheme, and let $(L_i)_{i\in I}$ be a family of invertible sheaves on S. We say that the L_i form an *ample family* if the equivalent conditions of (2.2.3) hold. In particular, a family consisting of a single sheaf L is ample if and only if L is ample in the usual sense (EGA II 4.5.3).

Definition 2.2.5. A scheme S is called *divisorial* if S is quasi-compact and quasi-separated and if there exists an ample family (2.2.4) of invertible $\mathcal{O}_S$-modules.

Lemma 2.2.6. Let X be a locally noetherian scheme. Let U be an open of X such that the inclusion $U \to X$ is affine, for example U affine and X separated. Then $X - U$ is purely of codimension 0 or 1; that is, at every maximal point x of $X - U$ one has $\dim \mathcal{O}_{X,x} = 0$ or 1. It is purely of codimension 1 if U contains the maximal points of X.

Proof. Put $Y = X - U$. Let x be a maximal point of Y and make the base change $X' = \mathrm{Spec}\,\mathcal{O}_{X,x} \to X$; one obtains a cartesian diagram

$$\begin{array}{ccc} U' & \longrightarrow & U \\ \downarrow & & \downarrow \\ X' & \longrightarrow & X. \end{array}$$

Let $Y' = X' - U'$. Since x is a maximal point of Y, Y' is just the closed point of X'. Since X' is affine, U' is an affine open of X'. We show that the dimension d of X' is 0 or 1. Indeed, one knows (SGA 2 V 5.7) that $H^d_{Y'}(X', \mathcal{O}_{X'}) \neq 0$. But if $d \geq 2$, then

$$H^d_{Y'}(X', \mathcal{O}_{X'}) = H^{d-1}(U', \mathcal{O}_{X'}),$$

and the latter group is zero because U' is affine and $d - 1 \geq 1$, a contradiction.

Remark 2.2.6.1. Without the separation hypothesis on X, (2.2.6) would be false for an affine open U of X, as shown by the example of the affine plane with the origin doubled (EGA I 5.5.11).

Proposition 2.2.7. Let S be a noetherian separated locally factorial scheme, that is, a scheme whose local rings are factorial. Then S is divisorial (2.2.5). In particular (EGA IV 21.11.1):

Corollary 2.2.7.1. Every noetherian regular separated scheme is divisorial.

Proof of 2.2.7. One may suppose that S is integral. Let $(S_i)_{i\in I}$ be a finite covering of S by nonempty affine opens. By (2.2.6), $S - S_i$ is purely of codimension 1; hence, by EGA IV 21.7.4, it is the support of a positive divisor. In other words, for each $i \in I$, there is an invertible sheaf L_i and a section $f_i \in \Gamma(S, L_i)$ such that $S_i = S_{f_i}$. The family (L_i) is then ample by (2.2.4), using (2.2.3 (ii)).

Remark 2.2.7.2. As in (2.2.6), the separation hypothesis on S is essential. Let S again be the affine plane with the origin doubled. Recall that S is obtained by gluing two copies of the affine plane $\mathbb{A}^2_k$ along the identity on the complement U of the origin O; hence there is a canonical projection

$$p : S \longrightarrow \mathbb{A}^2_k$$

which is an isomorphism over U, while $p^{-1}(O)$ consists of two points O_1 and O_2. An invertible sheaf on S is obtained by gluing two invertible sheaves on $\mathbb{A}^2_k$ by an isomorphism over U. Since every invertible sheaf on $\mathbb{A}^2_k$ is trivial, an invertible sheaf on S is defined by an element

$g \in \Gamma(U, \mathcal{O}_U^*)$. But g is necessarily constant, since the restriction $\Gamma(\mathbb{A}_k^2, \mathcal{O}_{\mathbb{A}^2}) \to \Gamma(U, \mathcal{O}_U)$ is an isomorphism, the origin being of depth 2 in the plane. Thus every invertible sheaf on S is trivial. It is immediate, on the other hand, that p induces an isomorphism

$$\Gamma(\mathbb{A}_k^2, \mathcal{O}_{\mathbb{A}^2}) \xrightarrow{\sim} \Gamma(S, \mathcal{O}_S).$$

Consequently every global section of $\mathcal{O}_S$ which vanishes at O_1 also vanishes at O_2, and the opens S_f, for $f \in \Gamma(S, \mathcal{O}_S)$, do not form a base for the topology of S.

Theorem 2.2.8. Let S be a divisorial scheme (2.2.5), and let $(L_i)_{i\in I}$ be an ample family of invertible $\mathcal{O}_S$-modules. Let $L(S)$ be the strictly full additive subcategory of $\mathrm{Qcoh}(S)$ generated by the $L_i^{\otimes(-n)}$, for $(i, n) \in I \times \mathbb{N}$. Let $E \in \mathrm{ob}\,\mathrm{D}(\mathrm{Qcoh}(S))$.

a) The categories $L(S)$ and $\mathrm{Loclib}(S)$ are quasi-liftable in $\mathrm{Qcoh}(S)$ (I 1.2) and quasi-stable under kernels of epimorphisms (I 1.2).

b) Let $n \in \mathbb{Z}$. For E to be n-pseudo-coherent, respectively pseudo-coherent, in the sense of (2.2.1), it is necessary and sufficient that E be so relative to $L(S)$ or to $\mathrm{Loclib}(S)$ (I 2.3). The canonical functors

$$\mathrm{K}^-(L(S))/\mathrm{K}^{-,\delta}(L(S)) \longrightarrow \mathrm{D}(\mathrm{Qcoh}(S)),$$

$$\mathrm{K}^-(\mathrm{Loclib}(S))/\mathrm{K}^{-,\delta}(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}(\mathrm{Qcoh}(S))$$

are fully faithful and have as essential image $\mathrm{D}^-(\mathrm{Qcoh}(S))_{\mathrm{coh}}$.

c) Let $[m, n]$ be an interval of $\mathbb{Z}$. For E to have perfect amplitude contained in $[m, n]$ (2.2.1), it is necessary and sufficient that E be isomorphic, in $\mathrm{D}(\mathrm{Qcoh}(S))$, to a complex F such that $F^i = 0$ for $i \notin [m, n]$, $F^i \in \mathrm{ob}\,L(S)$ for $i > m$, and F^m is locally free of finite type. The canonical functor

$$\mathrm{K}^b(\mathrm{Loclib}(S))/\mathrm{K}^{b,\delta}(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}(\mathrm{Qcoh}(S))$$

is fully faithful and has as essential image $\mathrm{D}(\mathrm{Qcoh}(S))_{\mathrm{parf}}$.

Proof. Let $F \to G$ be an epimorphism in $\mathrm{Qcoh}(S)$, with G of finite type. Since F is the inductive limit of its quasi-coherent subsheaves of finite type (EGA I 9.4.9), there exists, by (2.1.1 a)), a quasi-coherent subsheaf F' of finite type in F such that $F' \to F \to G$ is an epimorphism. By (2.2.3 (iii)), there is an epimorphism $E \to F'$, with $E \in \mathrm{ob}\,L(S)$; hence $E \to F' \to F \to G$ is an epimorphism. This proves that the category of quasi-coherent $\mathcal{O}_S$-modules of finite type is quasi-liftable in $\mathrm{Qcoh}(S)$, and a fortiori the same is true for $\mathrm{Loclib}(S)$ and for $L(S)$.

For the second assertion of a), apply (1.1) on the Zariski site of S, with $\mathcal{C}$ the fibered category $U \mapsto \mathrm{Qcoh}(U)$ and $\mathcal{C}_0$ the fibered category $U \mapsto L(U)$. Since every object of L is pseudo-coherent, the notions of n-pseudo-coherence and pseudo-coherence in the fibered category D(Qcoh) coincide with the same notions relative to L (I 2.14). Condition (ii) of (1.1) is satisfied by (2.2.3 (iii)), and thus (1.1 a)) gives the part of a) concerning $L(S)$. The assertion for $\mathrm{Loclib}(S)$ is proved similarly. Part b) follows immediately from (1.1 b), c)), taking into account that, if $E \in \mathrm{ob}\,\mathrm{D}(\mathrm{Qcoh}(S))$ is n-pseudo-coherent, then E lies in $\mathrm{D}^-(\mathrm{Qcoh}(S))$, since S is quasi-compact. An object of the fibered category Qcoh is locally in L if and only if it is locally free of finite type; hence L is locally liftable in Qcoh and locally stable under kernels of epimorphisms. Thus c) follows from (1.2), with $\mathcal{C} = \mathrm{Qcoh}$, $\mathcal{C}_0 = L$, and $\mathcal{C}_1 = \mathrm{Loclib}(S)$.

Proposition 2.2.9. The hypotheses and notation are those of (2.2.8), but assume moreover that S is separated or noetherian.

a) The canonical functors

$$\mathrm{K}^-(L(S))/\mathrm{K}^{-,\delta}(L(S)) \longrightarrow \mathrm{D}(S), \qquad \mathrm{K}^-(\mathrm{Loclib}(S))/\mathrm{K}^{-,\delta}(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}(S)$$

are fully faithful and have as essential image $\mathrm{D}^-(S)_{\mathrm{coh}}$. Moreover, if S is of finite cohomological dimension in the sense of (3.7), for example if the underlying space of S is noetherian of finite Krull dimension, then the functors

$$\mathrm{K}(L(S))/\mathrm{K}^{\delta}(L(S)) \longrightarrow \mathrm{K}(\mathrm{Loclib}(S))/\mathrm{K}^{\delta}(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}^-(S)_{\mathrm{coh}}$$

are equivalences of categories.

b) The canonical functor

$$\mathrm{K}^b(\mathrm{Loclib}(S))/\mathrm{K}^{b,\delta}(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}(S)$$

is fully faithful and has as essential image $\mathrm{D}(S)_{\mathrm{parf}}$ (I 4.9). For $E \in \mathrm{ob}\,\mathrm{D}(S)$ to have perfect amplitude contained in $[m,n]$ (I 4.8), it is necessary and sufficient that E be isomorphic, in $\mathrm{D}(S)$, to a complex F such that $F^i = 0$ for $i \notin [m,n]$, $F^i \in \mathrm{ob}\,L(S)$ for $i > m$, and F^m is locally free of finite type.

Proof. In view of (3.5) and (3.7), this is an immediate corollary of (2.2.8). The only point to check, and it follows trivially from (3.5), respectively (3.7), is that for an object E of $\mathrm{D}^-(\mathrm{Qcoh}(S))$, respectively of $\mathrm{D}(\mathrm{Qcoh}(S))$ when S has finite cohomological dimension in the sense of (3.7), the notions of pseudo-coherence and perfection of (2.2.1) coincide with the usual notions (I 2.15 and 4.9) after regarding E as an object of $\mathrm{D}(S)$.

Remark 2.2.10. a) If $S = \mathrm{Spec}\,A$ is affine, the family consisting of the single sheaf $\mathcal{O}_S$ is ample, and for it $L(S) = \mathrm{Lib}(S)$. It is also clear that the categories $\mathrm{K}^{-,\delta}(\mathrm{Lib}(S))$ and $\mathrm{K}^{-,\delta}(\mathrm{Loclib}(S))$ are reduced to zero objects. It follows from (2.2.9) that, writing $\mathrm{Mod}(A)$ for the category of A-modules and $\mathrm{D}(A) = \mathrm{D}(\mathrm{Mod}(A))$, the functor $R\Gamma_S : \mathrm{D}(S) \to \mathrm{D}(A)$ induces fully faithful functors

$$\mathrm{D}^-(S)_{\mathrm{coh}} \longrightarrow \mathrm{D}(A), \qquad \mathrm{D}(S)_{\mathrm{parf}} \longrightarrow \mathrm{D}(A),$$

whose essential images are respectively the triangulated subcategories $\mathrm{D}^-(A)_{\mathrm{coh}}$ and $\mathrm{D}(A)_{\mathrm{parf}}$, formed by complexes with bounded-above cohomology and pseudo-coherent, respectively perfect, relative to the subcategory $\mathrm{Lib}(A)$, respectively $\mathrm{Loclib}(A)$, of free, respectively projective, modules of finite type. There are commutative diagrams of equivalences of categories

$$\begin{array}{ccccc}
\mathrm{K}^{-,b}(\mathrm{Lib}(S)) & \longrightarrow & \mathrm{K}^{-,b}(\mathrm{Loclib}(S)) & \longrightarrow & \mathrm{D}^b(S)_{\mathrm{coh}} \\
{\scriptstyle \Gamma_S}\downarrow & & {\scriptstyle \Gamma_S}\downarrow & & \downarrow{\scriptstyle R\Gamma_S} \\
\mathrm{K}^{-,b}(\mathrm{Lib}(A)) & \longrightarrow & \mathrm{K}^{-,b}(\mathrm{Loclib}(A)) & \longrightarrow & \mathrm{D}^b(A)_{\mathrm{coh}},
\end{array}$$

$$\begin{array}{ccc}
\mathrm{K}^b(\mathrm{Loclib}(S)) & \longrightarrow & \mathrm{D}(S)_{\mathrm{parf}} \\
{\scriptstyle \Gamma_S}\downarrow & & \downarrow{\scriptstyle R\Gamma_S} \\
\mathrm{K}^b(\mathrm{Loclib}(A)) & \longrightarrow & \mathrm{D}(A)_{\mathrm{parf}}.
\end{array}$$

In the upper diagram, one may replace b by $-$ when S has finite cohomological dimension in the sense of (3.7).

b) For an arbitrary scheme S, it follows from a) that a complex of $\mathcal{O}_S$-modules which is pseudo-coherent and has bounded cohomology is locally isomorphic, in $\mathrm{D}(S)$, to a strictly pseudo-coherent complex, which was by no means evident a priori (cf. I 2.3.1).

2.3. Soft sheaves

2.3.1. Recall a few definitions and results from [T.F.]. Let X be a paracompact space. A sheaf of sets F on X is called *soft* if, for every closed subset Y of X, every section of F over Y extends to a section of F over X. Soft abelian sheaves are acyclic: if F is soft, then $H^i(X, F) = 0$ for $i > 0$ (T.F. II 4.4.3).

Let A be a sheaf of rings on X. If F is a soft A-module, then F is generated by its sections (cf. 2.1.1): indeed, the homomorphism $A_X^{(I)} \to F$ defined by $I = H^0(X, F)$ is an epimorphism. Moreover, if A is soft, every A-module is soft (T.F. II 3.7.1). Examples of soft sheaves of rings include the sheaf of continuous real or complex-valued functions on a paracompact space and the sheaf of C^∞ functions on a C^∞ manifold.

Proposition 2.3.2. Let S be a compact space equipped with a soft sheaf of rings A. Write $\mathrm{Mod}(S)$ for the category of left A-modules and $\mathrm{D}(S) = \mathrm{D}(\mathrm{Mod}(S))$.

a) The category $\mathrm{Lib}(S)$, respectively $\mathrm{Loclib}(S)$ (2.0), is liftable in $\mathrm{Mod}(S)$ and quasi-stable, respectively stable, under kernels of epimorphisms (I 1.2). This assertion holds more generally for S paracompact.

b) Let $E \in \mathrm{ob}\,\mathrm{D}(S)$ and $n \in \mathbb{Z}$. For E to be n-pseudo-coherent, respectively pseudo-coherent, it is necessary and sufficient that it be so relative to $\mathrm{Lib}(S)$ or to $\mathrm{Loclib}(S)$. The canonical functors
$$\mathrm{K}^-(\mathrm{Lib}(S)) \longrightarrow \mathrm{D}(S), \qquad \mathrm{K}^-(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}(S)$$
are fully faithful and have as essential image $\mathrm{D}^-(S)_{\mathrm{coh}}$ (I 2.15).

c) Let $E \in \mathrm{ob}\,\mathrm{D}(S)$ and let $[m, n]$ be an interval of $\mathbb{Z}$. For E to have perfect amplitude contained in $[m, n]$ (I 4.8), it is necessary and sufficient that there exist a quasi-isomorphism $F \to E$, where F is a complex such that $F^i = 0$ for $i \notin [m, n]$, $F^i \in \mathrm{ob}\,\mathrm{Lib}(S)$ for $i > m$, and $F^m \in \mathrm{ob}\,\mathrm{Loclib}(S)$. The canonical functor
$$\mathrm{K}^b(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}(S)$$
is fully faithful and has as essential image $\mathrm{D}(S)_{\mathrm{parf}}$ (I 4.9).

d) Let $\mathrm{Mod}(A(S))$ be the category of left $A(S)$-modules and $\mathrm{D}(A(S))$ the corresponding derived category. The functor
$$H^0(S, -) : \mathrm{Mod}(S) \longrightarrow \mathrm{Mod}(A(S))$$
is exact and is an equivalence of categories. Moreover it defines equivalences of categories
$$\mathrm{D}(S) \xrightarrow{\sim} \mathrm{D}(A(S)), \qquad \mathrm{D}^-(S)_{\mathrm{coh}} \xrightarrow{\sim} \mathrm{D}^-(A(S))_{\mathrm{coh}}, \qquad \mathrm{D}(S)_{\mathrm{parf}} \xrightarrow{\sim} \mathrm{D}(A(S))_{\mathrm{parf}},$$
where pseudo-coherence, respectively perfection, in $\mathrm{D}(A(S))$ is understood relative to the category of free, respectively projective, modules of finite type. It also gives an equivalence from the full subcategory of $\mathrm{D}(S)$ formed by n-pseudo-coherent objects, respectively by objects of perfect amplitude contained in $[m, n]$, onto the analogous full subcategory of $\mathrm{D}(A(S))$.

Proof. The first assertion of a) follows from (2.1.2 a)), applied with S the topos of sheaves of sets on S and $\mathcal{C}'_S = \mathrm{Mod}(S)$, using (2.3.1). The second follows from (1.1 a)), respectively (1.2 a)), with $\mathcal{C} = \mathrm{Mod}$ and $\mathcal{C}_0 = \mathrm{Lib}$, respectively Loclib; the condition (ii) of (1.1) is verified by (2.3.1) and (2.1.1 b)). Part b) follows from (1.1 b), c)) with the same $\mathcal{C}$ and $\mathcal{C}_0$. Part c) follows from (1.2 b), c), d)), with $\mathcal{C} = \mathrm{Mod}$ and $\mathcal{C}_0 = \mathrm{Lib}$. The first assertion of d) follows, using (2.3.1), from (2.1.2 b) (ii)) with $\mathcal{C}'_S = \mathcal{C}_S = \mathrm{Mod}(S)$. The other assertions in d) follow from it, together with b) and c), and from the fact that Γ_S carries free modules, respectively direct factors of free modules, of finite type to free, respectively projective, modules of finite type.

2.4. Stein spaces

Definition 2.4.1. Let S be a locally ringed topos (I 2.15.1 (ii)), with final object also denoted S. We say that S is *Stein* if the structural sheaf $\mathcal{O}_S$ is coherent (I 3.1) and if the following properties hold:

Theorem A: every coherent $\mathcal{O}_S$-module (I 3.1) is generated by its sections;

Theorem B: for every coherent $\mathcal{O}_S$-module F, one has $H^i(S, F) = 0$ for $i > 0$.

Remark 2.4.1.1. If S has enough closed points s such that the ideal $\mathfrak{m}_s$ defined by s is coherent, then the relation $H^1(S, F) = 0$ for every coherent sheaf F implies Theorem A. Indeed, let F be a coherent $\mathcal{O}_S$-module and let s be a closed point of S. There is an exact sequence

$$0 \longrightarrow \mathfrak{m}_s F \longrightarrow F \longrightarrow F/\mathfrak{m}_s F \longrightarrow 0,$$

where $F/\mathfrak{m}_s F$ is a coherent sheaf concentrated at s. Applying $H^0(S, -)$ and writing the cohomology exact sequence, one finds that

$$H^0(S, F) \longrightarrow H^0(S, F/\mathfrak{m}_s F)$$

is an epimorphism. Since

$$H^0(S, F/\mathfrak{m}_s F) = F_s/\mathfrak{m}_s F_s,$$

where $\mathfrak{m}_s$ is the maximal ideal of $\mathcal{O}_s$, Nakayama's lemma gives the conclusion. The editor does not know whether the preceding implication is true in general when one assumes only that $\mathcal{O}_S$ is a coherent sheaf of local rings. The editor also does not know whether the relation $H^1(S, F) = 0$ for every coherent sheaf F implies Theorem B.

Examples 2.4.2. A complex analytic Stein space, a compact convex subset of $\mathbb{C}^n$ equipped with the sheaf induced by the sheaf of holomorphic functions, the spectrum of a noetherian ring, and an affine rigid analytic space define Stein topoi.

Lemma 2.4.3. Let S be a Stein topos (2.4.1). Suppose that the final object S is quasi-compact (2.1.1), and let $\mathrm{Coh}(S)$ be the abelian category of coherent $\mathcal{O}_S$-modules, that is, modules of finite presentation. Then:

a) $\mathrm{Lib}(S)$, respectively $\mathrm{Loclib}(S)$, is liftable in $\mathrm{Coh}(S)$ and quasi-stable, respectively stable, under kernels of epimorphisms (I 1.2).

b) The canonical functors

$$\mathrm{K}^-(\mathrm{Lib}(S)) \longrightarrow \mathrm{K}^-(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}^-(\mathrm{Coh}(S))$$

are equivalences of categories.

c) Put $A = \Gamma(S, \mathcal{O}_S)$, and write $\mathrm{Mod}(A)$ for the category of A-modules and $\mathrm{D}(A)$ for the corresponding derived category. The functor

$$\Gamma_S : \mathrm{Coh}(S) \longrightarrow \mathrm{Mod}(A)$$

is exact, fully faithful, and has as essential image the strictly full additive subcategory of $\mathrm{Mod}(A)$ formed by A-modules of finite presentation. It induces a fully faithful functor

$$\mathrm{D}^-(\mathrm{Coh}(S)) \longrightarrow \mathrm{D}(A),$$

whose essential image is the full subcategory $\mathrm{D}^-(A)_{\mathrm{coh}}$ formed by complexes pseudo-coherent relative to the subcategory of free modules of finite type.

Here "enough closed points" means enough fiber functors (SGA 4 IV 6.4.1) of the form $i^* : S \to s$, with i_* the inclusion of a closed subtopos of S; and $\mathfrak{m}_s$ denotes the sections of $\mathcal{O}_S$ whose fiber at s belongs to the maximal ideal of $\mathcal{O}_s$.

Proof. For the first assertion of a), apply (2.1.2 a)) with $\mathcal{C}'_S = \mathrm{Coh}(S)$; the hypothesis of (2.1.2) is verified by Theorem B, since if E is coherent and G is locally free of finite type, then $\mathrm{Hom}(G, E)$ is coherent. Thus $\mathrm{Loclib}(S)$, and a fortiori $\mathrm{Lib}(S)$, is liftable in $\mathrm{Coh}(S)$. The second assertion of a) follows from (1.1 a)), respectively (1.2 a)), applied with $\mathcal{C}_0 = \mathrm{Lib}$, respectively Loclib; condition (ii) of (1.1) is verified by Theorem A and (2.1.1 b)). Part b) follows from (1.1 c)), applied successively with $\mathcal{C}_0 = \mathrm{Lib}$ and $\mathcal{C}_0 = \mathrm{Loclib}$. The first assertion of c) follows from (2.1.2 b)(i)), applied with $\mathcal{C}'_S = \mathrm{Coh}(S)$. To prove that $\Gamma_S : \mathrm{D}^-(\mathrm{Coh}(S)) \to \mathrm{D}(A)$ is fully faithful, it is enough, by b), to prove that the composite

$$\mathrm{K}^-(\mathrm{Lib}(S)) \longrightarrow \mathrm{D}^-(\mathrm{Coh}(S)) \longrightarrow \mathrm{D}(A)$$

is so. But this composite factors as

$$\mathrm{K}^-(\mathrm{Lib}(S)) \xrightarrow{\Gamma_S} \mathrm{K}^-(\mathrm{Lib}(A)) \longrightarrow \mathrm{D}(A),$$

where $\mathrm{Lib}(A)$ denotes the category of free A-modules of finite type; the first arrow is an equivalence of categories, and the second is fully faithful by (I 2.7 b)), applied with $\mathcal{C} = \mathrm{Mod}(A)$ and $\mathcal{C}_0 = \mathrm{Lib}(A)$, since $\mathrm{K}^{-,\delta}(\mathrm{Lib}(A)) = 0$. This proves the last assertion of c).

Lemma 2.4.4. Under the hypotheses of (2.4.3), the canonical functor

$$\mathrm{D}^b(\mathrm{Coh}(S)) \longrightarrow \mathrm{D}(S)$$

is fully faithful and has as essential image $\mathrm{D}^b(S)_{\mathrm{coh}}$ (I 2.15).

Proof. Apply (2.1.3) with $\mathcal{A} = \mathrm{Coh}(S)$, $\mathcal{B} = \mathrm{Mod}(S)$, and $\varphi : \mathcal{A} \to \mathcal{B}$ the inclusion functor. Since this functor is fully faithful, it is enough, by (2.1.3 a)(ii)), to check that for fixed $M \in \mathrm{ob}\,\mathrm{Coh}(S)$ and $n > 0$ the functor

$$L \longmapsto \mathrm{Ext}^n_{\mathrm{Mod}(S)}(L, M)$$

is coeffaceable on $L \in \mathrm{ob}\,\mathrm{Coh}(S)$. By Theorem A and (2.1.1 b)), every coherent $\mathcal{O}_S$-module is a quotient of a free module of finite type; and if L is free of finite type, then $\mathrm{Ext}^n_{\mathrm{Mod}(S)}(L, M) = 0$ by Theorem B. The assertion follows. Hence the functor $\mathrm{D}^b(\mathrm{Coh}(S)) \to \mathrm{D}(S)$ is fully faithful and has as essential image the full subcategory of $\mathrm{D}(S)$ formed by complexes with bounded coherent cohomology, which is precisely $\mathrm{D}^b(S)_{\mathrm{coh}}$ since $\mathcal{O}_S$ is coherent (I 3.5).

Proposition 2.4.5. With the hypotheses and notation of (2.4.3), one has:

a) The canonical functors

$$\mathrm{K}^{-,b}(\mathrm{Lib}(S)) \longrightarrow \mathrm{K}^{-,b}(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}^b(S)_{\mathrm{coh}}$$

are equivalences of categories. Moreover, the functor $R\Gamma_S : \mathrm{D}^b(S) \to \mathrm{D}^b(A)$ induces a fully faithful functor

$$R\Gamma_S : \mathrm{D}^b(S)_{\mathrm{coh}} \longrightarrow \mathrm{D}^b(A),$$

whose essential image is $\mathrm{D}^b(A)_{\mathrm{coh}}$, the triangulated subcategory of $\mathrm{D}(A)$ formed by complexes with bounded cohomology and pseudo-coherent relative to the category of free modules of finite type.

b) Let $E \in \mathrm{ob}\,\mathrm{D}(S)$, and let $[m, n]$ be an interval of $\mathbb{Z}$. If E has perfect amplitude contained in $[m, n]$ (I 4.5), then E is isomorphic to a complex F such that $F^i = 0$ for $i \notin [m, n]$, $F^i \in \mathrm{ob}\,\mathrm{Lib}(S)$ for $i > m$, and $F^m \in \mathrm{ob}\,\mathrm{Loclib}(S)$.

c) The canonical functor

$$\mathrm{K}^b(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}(S)_{\mathrm{parf}}$$

is an equivalence of categories (I 4.9). Moreover, $R\Gamma_S : \mathrm{D}^b(S) \to \mathrm{D}^b(A)$ induces a fully faithful functor

$$R\Gamma_S : \mathrm{D}(S)_{\mathrm{parf}} \longrightarrow \mathrm{D}^b(A),$$

whose essential image is $\mathrm{D}^b(A)_{\mathrm{parf}}$, the triangulated subcategory of $\mathrm{D}(A)$ formed by complexes perfect relative to the category of projective modules of finite type.

Proof. a) The functors

$$\mathrm{K}^{-,b}(\mathrm{Lib}(S)) \longrightarrow \mathrm{K}^{-,b}(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}^b(\mathrm{Coh}(S)) \longrightarrow \mathrm{D}^b(A)_{\mathrm{coh}}$$

are equivalences of categories by (2.4.3 b), c). Since the fully faithful functor $\Gamma_S : \mathrm{D}^b(\mathrm{Coh}(S)) \to \mathrm{D}(A)$ factors as

$$\mathrm{D}^b(\mathrm{Coh}(S)) \longrightarrow \mathrm{D}^b(S)_{\mathrm{coh}} \xrightarrow{R\Gamma_S} \mathrm{D}(A),$$

the conclusion follows from (2.4.4).

b) Suppose $\mathrm{parf.amp}(E) \subset [m, n]$. In particular E is pseudo-coherent; by a), after replacing E by an isomorphic object, we may assume that $E^i \in \mathrm{ob}\,\mathrm{Lib}(S)$ for $i > m$ and $E^i = 0$ for $i > n$. Truncating, we may also suppose that $E^i = 0$ for $i < m$. By (I 4.16), applied with $\mathcal{C} = \mathrm{Mod}$ and $\mathcal{C}_0 = \mathrm{Lib}$, one then has $E^m \in \mathrm{ob}\,\mathrm{Loclib}(S)$.

c) The hypotheses (1.1 (i)) and, respectively, (1.1 (ii)) are verified for $\mathcal{C} = \mathrm{Coh}(S)$ and $\mathcal{C}_0 = \mathrm{Lib}$, by (2.4.3 a)) and by (2.1.1 b)) together with Theorem A. Hence (1.2 c), d)) shows that the functor

$$\mathrm{K}^b(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}^b(\mathrm{Coh}(S))$$

is fully faithful. Therefore, by (2.4.4), the same is true for

$$\mathrm{K}^b(\mathrm{Loclib}(S)) \longrightarrow \mathrm{D}(S),$$

and its essential image is $\mathrm{D}(S)_{\mathrm{parf}}$ by b). By an argument analogous to that used in the proof of (2.4.3 c)), one sees that the functor $\mathrm{K}^b(\mathrm{Loclib}(S)) \to \mathrm{D}(S)$ induced by Γ_S is fully faithful and has essential image $\mathrm{D}^b(A)_{\mathrm{parf}}$; one finishes the proof as in a).

Remark 2.4.6. The editor does not know whether in (2.4.4) one may replace D^b by D^-, and consequently whether (2.4.5 a)) remains true when one replaces $\mathrm{K}^{-,b}$ by K^- and D^b by D^-.

We finish with an interesting complement to (2.4.5). First we give a definition.

Definition 2.4.7. A *complex pseudo-analytic space* is a ringed space locally isomorphic to a ringed space of the form $(Y, \mathcal{O}_X|Y)$, where X is a complex analytic space and Y is a closed subset of X.

The structural sheaf of a complex pseudo-analytic space is therefore coherent. We say that a complex pseudo-analytic space is Stein if the corresponding topos is Stein (2.4.1).

Exposé II. Global resolutions (continued)

Proposition 2.4.8. Let S be a compact Stein complex pseudo-analytic space (2.4.7). Suppose that, for every open U of S and every reduced closed subspace X of U, the normalization of X is locally connected. This condition is verified, for example, when S is locally defined by real analytic equations or inequalities in a space $\mathbb{R}^n$. Then

$$A = \Gamma(S, \mathcal{O}_S)$$

is a noetherian ring.

Proof. It is enough to show that, if M is an A-module of finite presentation, then the set of submodules of M, or equivalently the set of submodules of finite type of M, satisfies the maximal condition. Indeed, if N is a submodule of finite type of M, then M/N is of finite presentation by I 2.6 and 2.9, so that N is itself of finite presentation by the equivalence (2.4.3 c). Using again the equivalence (2.4.3 c) between the category of coherent $\mathcal{O}_S$-modules and the category of A-modules of finite presentation, together with the compactness of S, one is reduced to proving the following lemma.

Lemma 2.4.8.1. Let S be a complex pseudo-analytic space satisfying the local connectedness condition of (2.4.8). Let F be a coherent $\mathcal{O}_S$-module, let (E_n) be an increasing sequence of coherent sub-$\mathcal{O}_S$-modules of F, and let s be a point of S. Then there exists an open neighbourhood U of s such that the sequence $(E_n|U)$ is stationary.

Proof. Since the ring $\mathcal{O}_{S,s}$ is noetherian, there exists an integer n_0 such that $(E_n)_s = (E_{n_0})_s$ for $n \geq n_0$. Replacing the sequence (E_n) by the sequence (E_n/E_{n_0}), one may therefore suppose that $(E_n)_s = 0$ for every n. On the other hand $F_s = M$ is a finite $\mathcal{O}_{S,s}$-module; hence it has a finite filtration

$$M = M_0 \supset M_1 \supset \cdots \supset M_q = 0$$

such that

$$M_i/M_{i+1} \simeq \mathcal{O}_s/\mathfrak{p}_i,$$

where $\mathfrak{p}_i$ is a prime ideal of $\mathcal{O}_s$. Since the category of finite-type $\mathcal{O}_s$-modules is equivalent to the category of germs at s of coherent $\mathcal{O}_S$-modules, after shrinking around s one may suppose that the M_i, respectively the $\mathfrak{p}_i$, are the fibres at s of coherent sub-$\mathcal{O}_S$-modules F_i, respectively coherent ideals $\mathfrak{p}_i$, of F, respectively of $\mathcal{O}_S$, and that one has

$$F = F_0 \supset F_1 \supset \cdots \supset F_q = 0, \qquad F_i/F_{i+1} \simeq \mathcal{O}_S/\mathfrak{p}_i.$$

To prove that the sequence (E_n) is stationary in a neighbourhood of s is therefore equivalent to proving the same assertion for the induced sequences on the graded pieces of this filtration. Thus one may suppose that $F = \mathcal{O}_S$ and that $\mathcal{O}_{S,s}$ is an integral domain; the E_n then form an increasing sequence of ideals of $\mathcal{O}_S$ with $(E_n)_s = 0$.

Since $\mathcal{O}_{S,s}$ is an integral domain, hence in particular reduced, one may moreover suppose, by Oka's theorem, after localizing at s, that S is reduced. We have to show that there is an open neighbourhood U of s such that $E_n|U = 0$ for n large enough. Consider, to do this, the normalization $\widetilde{S}$ of S. It is the analytic spectrum of a finite $\mathcal{O}_S$-algebra $\widetilde{\mathcal{O}}_S$ whose fibre at each $t \in S$ is the integral closure of $\mathcal{O}_{S,t}$. Since $E_n \subset E_n\widetilde{\mathcal{O}}_S$, it is enough to prove that $E_n\widetilde{\mathcal{O}}_S = 0$ for n large. This reduces us to the case where S is normal.

In that case, since $(E_n)_s = 0$, the closed immersion

$$i_n : S_n \longrightarrow S$$

defined by E_n is étale at s. But, S being normal, the set of points at which i_n is étale is both open and closed by the lemma below. Hence its image in S is simultaneously open and closed. The restriction of E_n to the connected component of s in S is therefore zero; this component is open because S is locally connected. The lemma is proved.

Lemma 2.4.8.2 (cf. EGA IV 18.10.3). Let Y be a normal pseudo-analytic space, and let $f : X \to Y$ be a non-ramified morphism. The set of points of X at which f is étale is both open and closed.

Proof. It is immediate that the set of points at which f is étale is open. It remains to show that the set of points at which f is not étale is open. Since a non-ramified morphism is locally an

immersion, one may suppose that f is a closed immersion defined by a coherent ideal I. Let x be a point of X such that $I_x \neq 0$. Let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}_{Y,x}$ containing I_x. One has

$$\dim(\mathcal{O}_{Y,x}/\mathfrak{p}) > 0,$$

for otherwise $\mathfrak{p} = 0$, since $\mathcal{O}_{Y,x}$ is integral. Thus Y has positive codimension at x, hence positive codimension in a neighbourhood of x; the assertion follows.

3. Complements on quasi-coherent sheaves on schemes

3.0. In this section we fix a quasi-compact and quasi-separated scheme S. The canonical, fully faithful inclusion functor

$$\iota : \mathrm{Qcoh}(S) \longrightarrow \mathrm{Mod}(S)$$

extends to a functor, again denoted ι, from $\mathrm{D}(\mathrm{Qcoh}(S))$ to $\mathrm{D}(S) = \mathrm{D}(\mathrm{Mod}(S))$, which we shall study.

Lemma 3.1. The category $\mathrm{Qcoh}(S)$ is an abelian category satisfying AB5, and the quasi-coherent sheaves of finite type form a small family of generators. In particular $\mathrm{Qcoh}(S)$ has enough injectives.

Proof. The assertion about generators follows at once from the fact that every quasi-coherent sheaf on S is the filtered inductive limit of its quasi-coherent subsheaves of finite type (EGA I 9.4.9 and IV 1.7.7). The other assertions are evident.

Remark 3.1.1. The editor does not know whether $\mathrm{Qcoh}(S)$ still has enough injectives when one assumes only that S is quasi-separated.

Lemma 3.2. The functor

$$\iota : \mathrm{Qcoh}(S) \longrightarrow \mathrm{Mod}(S)$$

has a right adjoint

$$Q : \mathrm{Mod}(S) \longrightarrow \mathrm{Qcoh}(S),$$

called the coherer.

Proof. If S is affine, the existence of Q is immediate: one takes $Q = \widetilde{\Gamma_S}$ (EGA I 1.3.7). Let now $f : U \to S$ be an affine open of S. It is clear that, for $E \in \mathrm{ob}\,\mathrm{Qcoh}(S)$ and $F \in \mathrm{ob}\,\mathrm{Mod}(U)$, one has a canonical isomorphism

$$\mathrm{Hom}(E, f_*F) \simeq \mathrm{Hom}(E, f_*Q(F)). \tag{1}$$

Let $(f_i : U_i \to S)$ be a finite covering of S by affine opens, and, for each pair (i,j), let $(U_{ijk} \to U_i \cap U_j)_k$ be a finite covering of $U_i \cap U_j$ by affine opens, which is possible since S is quasi-separated. For $F \in \mathrm{ob}\,\mathrm{Mod}(S)$ one has an exact sequence

$$0 \longrightarrow F \longrightarrow \prod_i f_{i*}(F|U_i) \longrightarrow \prod_{i,j,k} f_{ijk*}(F|U_{ijk}), \tag{2}$$

where f_{ijk} denotes the inclusion of U_{ijk} into S. If $g : V \to U$ is an inclusion of affine opens of S, there is an evident natural arrow

$$Q(F|U) \longrightarrow g_*Q(F|V).$$

Consequently (2) gives an arrow

$$\prod_i f_{i*}Q(F|U_i) \longrightarrow \prod_{i,j,k} f_{ijk*}Q(F|U_{ijk}), \tag{3}$$

whose kernel we denote by QF. If $E \in \mathrm{ob}\,\mathrm{Qcoh}(S)$, applying the functor $\mathrm{Hom}(E, \cdot)$ to (2), and using (1), one obtains a functorial isomorphism in E,

$$\mathrm{Hom}(E, F) \simeq \mathrm{Hom}(E, QF).$$

This proves the existence of Q; its uniqueness is evident, since it is an adjoint.

Lemma 3.3.

a) The coherer is an additive functor and transforms injectives into injectives.

b) Let

$$RQ : \mathrm{D}^+(S) \longrightarrow \mathrm{D}^+(\mathrm{Qcoh}(S))$$

be the right derived functor of the coherer. For $E \in \mathrm{ob}\,\mathrm{D}(\mathrm{Qcoh}(S))$ and $F \in \mathrm{ob}\,\mathrm{D}^+(S)$ there are canonical functorial isomorphisms

$$R\,\mathrm{Hom}_{\mathrm{Mod}}(E, F) \simeq R\,\mathrm{Hom}_{\mathrm{Qcoh}}(E, RQ(F)), \tag{i}$$
$$\mathrm{Hom}_{\mathrm{Mod}}(E, F) \simeq \mathrm{Hom}_{\mathrm{Qcoh}}(E, RQ(F)). \tag{ii}$$

Proof. Assertion a) is an immediate consequence of the definition. For b), it is enough to establish the isomorphism (i), since (ii) follows by passing to cohomology. For this purpose one may suppose that F has injective components. Then QF has injective components by a), and the isomorphism (i) follows directly from the definition of Q.

Lemma 3.4. Let $f : X \to Y$ be a morphism of quasi-compact and quasi-separated schemes. For $E \in \mathrm{ob}\,\mathrm{Mod}(X)$ there is a canonical functorial isomorphism

$$Q_Y f_*(E) \simeq f_* Q_X(E).$$

Proof. Since f is quasi-compact and quasi-separated (EGA IV 1.2.3 and 1.2.4), f_* transforms quasi-coherent sheaves into quasi-coherent sheaves (EGA III 1.4.10 and IV 1.7.21). The functors $Q_Y f_*$ and $f_* Q_X$ from $\mathrm{Mod}(X)$ to $\mathrm{Qcoh}(Y)$ are therefore both right adjoints to the functor

$$f^* : \mathrm{Qcoh}(Y) \longrightarrow \mathrm{Mod}(X),$$

and hence are canonically isomorphic.

Proposition 3.5. If S is noetherian, or quasi-compact and separated, the functor

$$\iota : \mathrm{D}^+(\mathrm{Qcoh}(S)) \longrightarrow \mathrm{D}^+(S)$$

is fully faithful and has as essential image the full subcategory $\mathrm{D}^+(S)_{\mathrm{qcoh}}$ of $\mathrm{D}^+(S)$ formed by complexes with quasi-coherent cohomology.

Proof. One may restrict to proving the assertion in the case where S is separated, since the noetherian case is already known. It is plainly equivalent to prove the following two assertions.

(3.5.1) For $E \in \mathrm{ob}\,\mathrm{D}^+(\mathrm{Qcoh}(S))$, the adjunction arrow

$$E \longrightarrow RQ(E)$$

is an isomorphism.

(3.5.2) For $E \in \mathrm{ob}\,\mathrm{D}^+(S)_{\mathrm{qcoh}}$, the adjunction arrow

$$RQ(E) \longrightarrow E$$

is an isomorphism.

Proof of (3.5.1). By an immediate dévissage one is reduced to proving that quasi-coherent sheaves are acyclic for the coherer, that is, for $E \in \mathrm{ob}\,\mathrm{Qcoh}(S)$, one has $R^iQ(E) = 0$ for $i > 0$, and that, moreover, the adjunction arrow $E \to QE$ is an isomorphism. If S is affine, this follows from the formula $Q = \widetilde{\Gamma_S}$ used in the proof of (3.2). In the general case, cover S by a finite number of affine opens U_i. Since S is separated, the inclusions

$$f_{i_0\dots i_p} : U_{i_0} \cap \cdots \cap U_{i_p} \longrightarrow S$$

are affine morphisms. Let $E \in \mathrm{ob}\,\mathrm{Qcoh}(S)$, and consider the resolution of E defined by this covering,

$$0 \longrightarrow E \longrightarrow \prod_i f_{i*}f_i^*E \longrightarrow \cdots \longrightarrow \prod_{i_0\dots i_p} f_{i_0\dots i_p*}f_{i_0\dots i_p}^*E \longrightarrow \cdots . \qquad (*)$$

It gives a spectral sequence

$$E_1^{pq} = \prod_{i_0\dots i_p} R^qQ(f_{i_0\dots i_p*}f_{i_0\dots i_p}^*E) \Longrightarrow R^{p+q}Q(E). \qquad (**)$$

Since $f_{i_0\dots i_p}$ is affine, (3.4) gives, for every q,

$$R^qQ(f_{i_0\dots i_p*}f_{i_0\dots i_p}^*E) \simeq f_{i_0\dots i_p*}R^qQ(f_{i_0\dots i_p}^*E). \qquad (***)$$

In particular $E_1^{pq} = 0$ for $q > 0$, by the affine case already treated. From (**) one deduces isomorphisms

$$R^nQ(E) \simeq H^n(QE') \quad (n \geq 0),$$

where E' is the resolution of E defined by the exact sequence (*). But by (***) one has $QE^n \simeq E^n$ for $n \geq 0$; hence finally

$$R^nQ(E) = 0 \quad (n > 0),$$

and $Q(E) \simeq E$. This proves (3.5.1).

Proof of (3.5.2). The spectral sequence

$$R^pQ(H^q(E)) \Longrightarrow R^{p+q}Q(E)$$

reduces us immediately to the case where $E \in \mathrm{ob}\,\mathrm{Qcoh}(S)$. The composite

$$E \longrightarrow RQE \longrightarrow E$$

of the adjunction arrows is the identity, and the assertion follows from (3.5.1). This completes the proof of (3.5).

Remark 3.6. The conclusion of (3.5) would be false if one omitted the hypothesis "separated or noetherian", as is shown by a neat counterexample of J.-L. Verdier; see Appendix I to the present exposé.

Proposition 3.7. Under the hypothesis of (3.5), suppose moreover that there is an integer N such that, for every $F \in \mathrm{ob}\,\mathrm{Mod}(S)$ and every quasi-compact open U of S, one has

$$H^i(U, F) = 0 \quad \text{for } i > N.$$

Then:

a) The coherer has finite cohomological dimension.

b) The functor

$$\iota : \mathrm{D}(\mathrm{Qcoh}(S)) \longrightarrow \mathrm{D}(S)$$

is fully faithful and has as essential image the full subcategory $\mathrm{D}(S)_{\mathrm{qcoh}}$ of $\mathrm{D}(S)$ formed by complexes with quasi-coherent cohomology.

Proof of a). If S is affine, the formula $Q = \widetilde{\Gamma_S}$ implies that Q is of cohomological dimension $\leq N$. We pass to the general case. Let us show that there is an integer a such that $R^qQ(E) = 0$ for every $E \in \mathrm{ob}\,\mathrm{Mod}(S)$ and every $q > a$. The hypothesis implies that every $E \in \mathrm{ob}\,\mathrm{Mod}(S)$ admits a finite right resolution E' of length N such that the E^i are acyclic, that is, $H^q(U, E^i) = 0$ for every open U of S and every $q > 0$. Thus it is enough to prove that there is an integer b such that

$$R^qQ(E) = 0$$

for every acyclic $\mathcal{O}_S$-module E and every $q > b$; one may then take $a = b + N$.

Let (U_i) be a finite covering of S by N' affine opens. Let E be an acyclic $\mathcal{O}_S$-module and let $C'(E)$ be the resolution of E defined by the covering (U_i). There are two cases.

If S is separated, the components of $C'(E)$ are sums of terms of the form f_*f^*E, where $f : U \to S$ is the inclusion of an affine open, hence an affine morphism. One has

$$RQ(Q_X f_*)f^*E \simeq RQ\, Rf_*f^*E \simeq RQ\, f_*f^*E,$$

since f^*E is acyclic. On the other hand, by (3.4),

$$R(Q_X f_*)f^*E \simeq R(f_*Q_X)f^*E \simeq f_*RQf^*E,$$

since f is affine. Hence

$$R^nQ(f_*f^*E) \simeq f_*R^nQ(f^*E) \quad (n \geq 0).$$

By the affine case,

$$R^nQ(f_*f^*E) = 0 \quad (n > N).$$

Since $C'(E)$ has length N', it follows that

$$R^nQ(E) = 0 \quad (n > N + N').$$

If S is noetherian, the components of $C'(E)$ are sums of terms of the same form f_*f^*E, where now $f : U \to S$ is the inclusion of a quasi-compact and separated open. As in the first case, one has

$$R(Q_X f_*)f^*E \simeq RQ\, f_*f^*E.$$

Since U is noetherian, $\mathrm{Qcoh}(U)$ has enough injective objects in $\mathrm{Mod}(U)$, and hence the right derived functor of $f_* : \mathrm{Qcoh}(U) \to \mathrm{Qcoh}(S)$ is induced by $Rf_* : \mathrm{D}^+(U) \to \mathrm{D}^+(S)$ when $\mathrm{D}^+(\mathrm{Qcoh}(U))$ and $\mathrm{D}^+(\mathrm{Qcoh}(S))$ are identified with full subcategories of $\mathrm{D}^+(U)$ and $\mathrm{D}^+(S)$ by (3.5). Thus

$$R(f_*Q_X)f^*E \simeq Rf_*RQf^*E.$$

One deduces a spectral sequence

$$E_2^{pq} = R^pf_*R^qQ(f^*E) \Longrightarrow R^{p+q}(f_*Q)f^*E.$$

By the first case there is an integer $n(U)$ depending only on U such that Q is of cohomological dimension $< n(U)$ on $\mathrm{Mod}(U)$; hence $E_2^{pq} = 0$ for $q > n(U)$. Also $E_2^{pq} = 0$ for $p > N$, by the cohomological-dimension hypothesis on S. Thus

$$R^n(f_*Q)f^*E = 0 \quad (n > N + N''),$$

where N'' is an integer greater than all the $n(U)$, with U running over the intersections $U_{i_0} \cap \cdots \cap U_{i_p}$. Taking account of the preceding displayed isomorphism, one obtains

$$R^n Q(f_* f^* E) = 0 \quad (n > N + N''),$$

and hence finally

$$R^n Q(E) = 0 \quad (n > N + N' + N'').$$

This proves a).

Proof of b). The coherer, being of finite cohomological dimension by a), admits a right derived functor

$$RQ : \mathrm{D}(S) \longrightarrow \mathrm{D}(\mathrm{Qcoh}(S))$$

whose restriction to $\mathrm{D}^+(S)$ coincides with the functor RQ defined above. For $E \in \mathrm{ob}\,\mathrm{D}(\mathrm{Qcoh}(S))$ there is a canonical functorial isomorphism

$$E \xrightarrow{\sim} RQ(E), \tag{1}$$

since, by (3.5.1), the E^i are acyclic for Q and satisfy $E^i \xrightarrow{\sim} Q(E^i)$. On the other hand, for $E \in \mathrm{ob}\,\mathrm{D}(S)$ one has a canonical functorial homomorphism

$$RQ(E) \longrightarrow E, \tag{2}$$

which, in the case where the E^i are Q-acyclic, comes from the ordinary adjunction homomorphism between ι and Q. It is checked directly that these homomorphisms make

$$RQ : \mathrm{D}(S) \longrightarrow \mathrm{D}(\mathrm{Qcoh}(S))$$

a right adjoint of

$$\iota : \mathrm{D}(\mathrm{Qcoh}(S)) \longrightarrow \mathrm{D}(S).$$

The fact that (1) is an isomorphism implies that ι is fully faithful. Finally, using the spectral sequence

$$R^p Q(H^q(E)) \Longrightarrow R^{p+q} Q(E),$$

which converges since Q has finite cohomological dimension, one sees that (2) is an isomorphism for $E \in \mathrm{ob}\,\mathrm{D}(S)_{\mathrm{qcoh}}$; hence ι has image $\mathrm{D}(S)_{\mathrm{qcoh}}$. This proves b) and completes the proof of (3.7).

Appendix I. A counterexample of Verdier

0. Introduction

If S is a scheme, write $\mathrm{Mod}(S)$, respectively $\mathrm{Qcoh}(S)$, for the category of $\mathcal{O}_S$-modules, respectively of quasi-coherent $\mathcal{O}_S$-modules. The purpose of this appendix is to draw attention to certain pathological properties of the category $\mathrm{D}(\mathrm{Qcoh}(S))$, and in particular to prove the following facts.

0.1. Let X be an affine scheme with ring A, and let I be an injective A-module. We know that, if A is noetherian, the sheaf $\widetilde{I}$ is an injective $\mathcal{O}_X$-module. If A is not noetherian, $\widetilde{I}$ is not necessarily injective, nor even flasque, even if the underlying space of X is noetherian of finite Krull dimension. Moreover, the restriction of $\widetilde{I}$ to an open U of X is not, in general, an injective object of $\mathrm{Qcoh}(U)$.

0.2. Let $f : X \to Y$ be a morphism of quasi-compact and quasi-separated schemes. The functor

$$Rf_* : \mathrm{D}^+(X) \longrightarrow \mathrm{D}^+(Y)$$

does not in general induce, on $\mathrm{D}^+(\mathrm{Qcoh}(X))$ and $\mathrm{D}^+(\mathrm{Qcoh}(Y))$, the right derived functor of

$$f_* : \mathrm{Qcoh}(X) \longrightarrow \mathrm{Mod}(Y).$$

More precisely, an injective object of $\mathrm{Qcoh}(X)$ is not necessarily acyclic for $f_* : \mathrm{Mod}(X) \to \mathrm{Mod}(Y)$.

0.3. Let S be a quasi-compact and quasi-separated scheme. An object of $\mathrm{Qcoh}(S)$, even an injective object, is not necessarily acyclic for the coherer (II 3.2). The functor

$$\iota : \mathrm{D}^b(\mathrm{Qcoh}(S)) \longrightarrow \mathrm{D}^b(S)$$

is not in general fully faithful.

1. The counterexamples

We first recall the following lemma (SGA 2 II 9).

Lemma 1.1. Let A be a ring, $X = \mathrm{Spec}(A)$, let $\mathbf{f} = (f_\alpha)$ be a finite system of elements of A, and let Y be the closed subset defined by $\mathbf{f}(x) = 0$. For $i > 0$, the following conditions are equivalent:

(i) for every injective A-module I, one has $H^i_Y(X, \widetilde{I}) = 0$;

(ii) the pro-object $n \mapsto H_i(\mathbf{f}^n, A)$ is zero, that is, for every n there exists $n' \geq n$ such that

$$H_i(\mathbf{f}^{n'}, A) \longrightarrow H_i(\mathbf{f}^n, A)$$

is zero.

1.2. We shall use (1.1) to prove (0.1). Let k be a field,

$$B = k[x, y], \qquad \mathbf{f} = (x, y), \qquad M = \bigoplus_{n>0} B/(\mathbf{f}^n),$$

and let A be the B-algebra $D_B(M)$ (EGA 0_{IV} 18.2.3). One has trivially

$$H_2^A(\mathbf{f}^n, A) \simeq H_2^B(\mathbf{f}^n, A).$$

On the other hand,

$$H_2^B(\mathbf{f}^n, A) \simeq H_2^B(\mathbf{f}^n, B) \oplus H_2^B(\mathbf{f}^n, M),$$

and

$$H_2^B(\mathbf{f}^n, B) = 0,$$

since $\mathbf{f}$ is a regular sequence. Thus

$$H_2^B(\mathbf{f}^n, A) \simeq H_2^B(\mathbf{f}^n, M).$$

Finally,

$$H_2^B(\mathbf{f}^n, M) \simeq H_B^0(\mathbf{f}^n, M),$$

where $H_B^0(\mathbf{f}^n, M)$ is canonically identified with the submodule $(\mathbf{f}^n, M)$ of M annihilated by $\mathbf{f}^n$. Hence

$$H_2^A(\mathbf{f}^n, A) \simeq (\mathbf{f}^n, M). \qquad (*)$$

Since the transition morphism

$$H_2^A(\mathbf{f}^{n'}, A) \longrightarrow H_2^A(\mathbf{f}^n, A)$$

is induced by multiplication by $\mathbf{f}^{n'-n}$, one checks immediately from (*) that the pro-object $n \mapsto H_2^A(\mathbf{f}^n, A)$ is not zero. Hence, by (1.1), there is an injective A-module I such that

$$H_Y^2(X, \widetilde{I}) \neq 0,$$

and therefore $\widetilde{I}$ is not flasque. Notice also that the projection $\mathrm{Spec}(A) \to \mathrm{Spec}(B)$ is a homeomorphism, so that the underlying space of X is noetherian of dimension 2. If U denotes the complement of Y in X, then by SGA 2 II 4,

$$H_Y^2(X, I) \simeq H^1(U, I) \neq 0.$$

But, since U is separated, the functor $\mathrm{D}^+(\mathrm{Qcoh}(U)) \to \mathrm{D}^+(U)$ is fully faithful by II 3.5, so $\widetilde{I}|U$ is not injective in $\mathrm{Qcoh}(U)$. This proves assertion (0.1).

Let Z be the quasi-compact and quasi-separated scheme obtained by gluing two copies of X along U; let j_1, j_2 be the two canonical open immersions of X into Z. Thus one has a Cartesian square

$$\begin{array}{ccc} U & \xrightarrow{i} & X \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle j_1} \\ X & \xrightarrow[j_2]{} & Z. \end{array}$$

One has

$$j_2^* R^1 j_{1*}(\widetilde{I}) \simeq R^1 i_*(i^* \widetilde{I}),$$

and hence

$$H^0(X, R^1 j_{1*}(\widetilde{I})) \simeq H^1(U, \widetilde{I}) \neq 0,$$

so that $R^1 j_{1*}(\widetilde{I}) \neq 0$, which proves (0.2).

On the other hand, by II 3.4 and 3.5 one has

$$RQ\, Rj_{1*}(\widetilde{I}) \simeq j_{1*}(\widetilde{I}).$$

It follows from this a spectral sequence whose exact sequence in low degrees gives the isomorphism

$$R^1 j_{1*}(\widetilde{I}) \simeq R^2 Q(j_{1*} \widetilde{I}).$$

Since the sheaf $j_{1*}\widetilde{I}$ is injective in $\mathrm{Qcoh}(Z)$, the first part of (0.3) is proved.

Finally, let $E \in \mathrm{ob}\,\mathrm{Qcoh}(Z)$. We have the duality isomorphism

$$R\,\mathrm{Hom}_{\mathrm{Mod}}(E, Rj_{1*}\widetilde{I}) \simeq R\,\mathrm{Hom}_{\mathrm{Mod}}(j_1^* E, \widetilde{I}),$$

but, since X is affine, II 3.5 gives

$$R\,\mathrm{Hom}_{\mathrm{Mod}}(j_1^* E, \widetilde{I}) \simeq R\,\mathrm{Hom}_{\mathrm{Qcoh}}(j_1^* E, I) \simeq \mathrm{Hom}(j_1^* E, I).$$

Consequently

$$R\,\mathrm{Hom}_{\mathrm{Mod}}(E, Rj_{1*}\widetilde{I}) \simeq \mathrm{Hom}(j_1^* E, I).$$

A spectral sequence then gives, in low degree, the isomorphism

$$\mathrm{Ext}^2_{\mathrm{Mod}}(E, j_{1*}\widetilde{I}) \simeq \mathrm{Hom}(E, R^1 j_{1*}\widetilde{I}).$$

Thus the identity morphism of $E = R^1 j_{1*}\widetilde{I}$ supplies a non-zero element of

$$\mathrm{Ext}^2_{\mathrm{Mod}}(E, j_{1*}\widetilde{I}).$$

It follows that the functor

$$\mathrm{D}^b(\mathrm{Qcoh}(Z)) \longrightarrow \mathrm{D}^b(Z)$$

is not fully faithful. This completes the proof of (0.3).

Appendix II. Definition of the analytic index of a relative elliptic complex

In this appendix we propose to show that the notion of a perfect complex leads to a simple and natural definition of the "analytic index" of a continuous family of elliptic differential operators, or more generally of a relative elliptic complex. For the initiated reader, let us say that the definition given here has the advantage, compared with the classical definitions (see for example [2] and [17]), of not requiring any deformation of the elliptic complex under consideration.

Sections 1 and 2 consist of reminders on the classical notion of a "mixed structure". [16] We give, of course, only the minimum of definitions and results required in order to state and prove, in Section 3, the central theorem we have in view. It says, more precisely, that the direct image, by the projection (assumed proper) onto the base (assumed locally compact), of a relative elliptic complex is a perfect complex. When the base S is compact, the definition of the analytic index as an element of $K(S)$, the Grothendieck group of complex vector bundles of finite rank on S, then follows from the globalization sorite of II 2.3.2.

Throughout what follows, if S is a topological space, $\mathcal{O}_S$ will denote the sheaf of continuous real-valued functions on S.

1. The sorite of mixed structures

In this section a topological space S is fixed.

1.1. Definition of mixed varieties

Let V be an open subset of $\mathbb{R}^n$. For $r \in \mathbb{N}$ one writes $C^r(V)$ for the Fréchet space of real-valued functions of class C^r on V. Put

$$C^\infty(V) = \lim_r C^r(V).$$

Let U be an open subset of S. For $r \in \mathbb{N} \cup \{\infty\}$, denote by ${}^r\mathcal{O}_{U\times V}$ the sheaf of rings on $U \times V$ defined by

$$\Gamma(U' \times V', {}^r\mathcal{O}_{U\times V}) = C(U', C^r(V')),$$

where U' (respectively V') is an open subset of U (respectively of V), and $C(U', C^r(V'))$ denotes the space of continuous maps from U' into $C^r(V')$. There is a canonical injection

$$\mathrm{pr}_1^{-1}(\mathcal{O}_U) \longrightarrow {}^r\mathcal{O}_{U\times V}$$

which makes $(U \times V, {}^r\mathcal{O}_{U\times V})$ into a ringed space over U.

A ringed space X over S is said to be a *mixed variety of class* C^r ($r \in \mathbb{N} \cup \{\infty\}$) if X is locally isomorphic, as a ringed space over S, to a space of the type just described. If S is reduced to one point, a mixed variety of class C^r over S is just a variety of class C^r in the usual sense.

Let $f : X \to S$ be a mixed variety of class C^r. For $s \in S$, the fiber $X_s = f^{-1}(s)$, endowed with the sheaf $i_s^{-1}(\mathcal{O}_X)/I_s$, where $i_s : X_s \to X$ is the injection and I_s is the ideal of sections which vanish on X_s, is a variety of class C^r.

[16] The informed reader is advised to skip them.

1.2. Relative differential operators

It is easy, on the model of algebraic geometry (EGA IV 16, SGA 3 VII), to develop an infinitesimal study of mixed varieties. We shall only review rapidly the notions we shall need.

1.2.1. Let $f : X \to S$ be a mixed variety of class C^∞. For each $n \in \mathbb{N}$ one defines the sheaf $P^n_{X/S}$ of principal parts of order n on X. In two different ways, corresponding to the two projections pr_1 and pr_2 of $X \times_S X$ onto X, it is an $\mathcal{O}_X$-algebra augmented toward $\mathcal{O}_X$, and is locally free of finite type as an $\mathcal{O}_X$-module. When the $\mathcal{O}_X$-module structure on $P^n_{X/S}$ is not specified, it will be understood to be the one coming from pr_1. One has the canonical identifications

$$P^0_{X/S} = \mathcal{O}_X, \qquad P^1_{X/S}/\mathcal{O}_X = \Omega^1_{X/S}.$$

The sheaf $\Omega^1_{X/S}$ is the sheaf of relative differentials of X over S, or relative cotangent sheaf. Its dual is denoted $T_{X/S}$ and called the relative tangent sheaf. The sheaf $T_{X/S}$, respectively $\Omega^1_{X/S}$, is the sheaf of sections of a vector bundle of finite rank on X, called the relative tangent, respectively cotangent, bundle; these bundles are mixed varieties over X.

The $f^{-1}(\mathcal{O}_S)$-linear homomorphism, corresponding to the $\mathcal{O}_X$-algebra structure defined by pr_2,

$$d^n_{X/S} : \mathcal{O}_X \longrightarrow P^n_{X/S},$$

which associates to a section of $\mathcal{O}_X$ its principal part of order n, is called the universal differential operator of order n on X relative to S.

1.2.2. More generally, if E is a locally free $\mathcal{O}_X$-module of finite type, one may consider the sheaf of principal parts of order n of E,

$$P^n_{X/S}(E) = P^n_{X/S} \otimes_{\mathcal{O}_X} E,$$

where the tensor product is defined by means of the second $\mathcal{O}_X$-module structure on $P^n_{X/S}$. One has a universal differential operator

$$d^n_{X/S}(E) : E \longrightarrow P^n_{X/S}(E).$$

Let E, F be locally free $\mathcal{O}_X$-modules of finite type. By definition, a differential operator from E to F of order $\leq n$ is an $f^{-1}(\mathcal{O}_S)$-linear homomorphism from E to F which factors through $d^n_{X/S}(E)$ as an $\mathcal{O}_X$-linear homomorphism $P^n_{X/S}(E) \to F$; the factorization is then unique. In other words, $d^n_{X/S}(E)$ gives a bijection

$$\mathrm{Hom}_{\mathcal{O}_X}(P^n_{X/S}(E), F) \xrightarrow{\sim} \mathrm{Diff}^n(E, F), \tag{1.2.2.1}$$

where $\mathrm{Diff}^n(E, F)$ denotes the set of differential operators from E to F of order $\leq n$.

1.2.3. We shall also have to consider differential operators with complex coefficients. Let $\mathcal{O}_X \otimes \mathbb{C}$ (respectively $\mathcal{O}_S \otimes \mathbb{C}$) be the complexification of $\mathcal{O}_X$ (respectively $\mathcal{O}_S$). Let E, F be locally free $(\mathcal{O}_X \otimes \mathbb{C})$-modules of finite type. By a differential operator from E to F of order $\leq n$ one means an $f^{-1}(\mathcal{O}_S \otimes \mathbb{C})$-linear homomorphism from E to F which factors through $d^n_{X/S}(E)$ as an $(\mathcal{O}_X \otimes \mathbb{C})$-linear homomorphism $P^n_{X/S}(E) \to F$. If $\mathrm{Diff}^n_{\mathbb{C}}(E, F)$ denotes the set of such operators, $d^n_{X/S}(E)$ therefore defines a bijection

$$\mathrm{Hom}_{\mathcal{O}_X \otimes \mathbb{C}}(P^n_{X/S}(E), F) \xrightarrow{\sim} \mathrm{Diff}^n_{\mathbb{C}}(E, F). \tag{1.2.3.1}$$

1.2.4. For $n \geq 1$ there is a canonical exact sequence

$$0 \longrightarrow S^n(\Omega^1_{X/S}) \longrightarrow P^n_{X/S} \longrightarrow P^{n-1}_{X/S} \longrightarrow 0.$$

Hence, tensoring over $\mathcal{O}_X$ with a locally free $\mathcal{O}_X$-module, respectively $(\mathcal{O}_X \otimes \mathbb{C})$-module, E of finite type, one obtains an exact sequence

$$0 \longrightarrow S^n(\Omega^1_{X/S}) \otimes E \longrightarrow P^n_{X/S}(E) \longrightarrow P^{n-1}_{X/S}(E) \longrightarrow 0. \tag{1.2.4.1}$$

Here $S^n(\Omega^1_{X/S})$ denotes the n-th symmetric power.

Let F be a locally free $\mathcal{O}_X$-module, respectively $(\mathcal{O}_X \otimes \mathbb{C})$-module, of finite type. Applying $\mathrm{Hom}(\ ,F)$, respectively $\mathrm{Hom}_{\mathcal{O}_X \otimes \mathbb{C}}(\ ,F)$, to (1.2.4.1), and using (1.2.2.1) and (1.2.3.1), one obtains an exact sequence

$$0 \longrightarrow \mathrm{Diff}^{n-1}(E,F) \longrightarrow \mathrm{Diff}^n(E,F) \xrightarrow{\sigma_n} \mathrm{Hom}_{\mathcal{O}_X}\big(S^n(\Omega^1_{X/S}) \otimes E, F\big), \tag{1.2.4.2}$$

and analogously in the complex case. If X is paracompact and $\mathcal{O}_X$ is soft, the sequence may be completed on the right by adding a zero. The homomorphism σ_n is called the *symbol*. It associates to a differential operator from E to F of order $\leq n$ a homogeneous polynomial map of degree n from $T^*_{X/S}$ into $\mathrm{Hom}(E,F)$, or equivalently a homomorphism $p^*E \to p^*F$, where p is the projection of the relative cotangent bundle onto X, satisfying the usual homogeneity condition.

Let E, F, G be locally free $\mathcal{O}_X$-modules of finite type, $u \in \mathrm{Diff}^n(E,F)$ and $v \in \mathrm{Diff}^m(F,G)$. Then $vu \in \mathrm{Diff}^{m+n}(E,G)$ and one checks at once the relation

$$\sigma_{m+n}(vu) = \sigma_m(v)\sigma_n(u). \tag{1.2.4.3}$$

The same relation holds for differential operators with complex coefficients. In particular, if the composite of two differential operators is zero, then the composite of their symbols is zero.

1.2.5. Let $E^\bullet$ be a bounded complex of differential operators with complex coefficients on X relative to S, and let $d^i : E^i \to E^{i+1}$ be of order n_i. By (1.2.4.3),

$$\sigma_{n_{i+1}}(d^{i+1})\sigma_{n_i}(d^i) = 0.$$

The complex $E^\bullet$ is called an *elliptic complex of order* (n_i) if the symbol complex on the relative cotangent bundle, pulled back to that bundle, is acyclic outside the zero section.

When S is reduced to one point, this notion of elliptic complex on X coincides with the usual one, studied in detail in [4] and [16].

1.2.6. Let $s \in S$, and let i_s be the inclusion of the fiber X_s in X, considered as a monomorphism of ringed spaces (1.1). For $n \in \mathbb{N}$ one has a canonical isomorphism

$$i_s^* P^n_{X/S} \simeq P^n_{X_s},$$

and hence a restriction homomorphism

$$i_s^* : \mathrm{Diff}^n(E,F) \longrightarrow \mathrm{Diff}^n(i_s^*E, i_s^*F),$$

for E, F locally free $\mathcal{O}_X$-modules of finite type, and similarly for operators with complex coefficients. If $E^\bullet$ is a bounded complex of differential operators with complex coefficients on X, then $E^\bullet$ is elliptic if and only if, for every $s \in S$, $i_s^*(E^\bullet)$ is an elliptic complex. The verification is left to the reader.

2. Rigidity lemmas

2.0. It is "well known" that compact differentiable varieties are rigid, that is, they admit no continuous deformation other than the trivial one. Since this result will be used essentially in

Section 3, and references seem rather scarce, it is perhaps useful to give precise statements and a few proofs.

A topological space S is fixed. The mixed varieties under consideration are assumed to be of class C^r, with $r \gg 1$; possibly $r = \infty$.

2.1. Notation. Let X, Y be mixed S-varieties. We denote by $\mathrm{Hom}(X, Y)$ the set of S-morphisms from X to Y, and by $\mathcal{H}om(X, Y)$ the sheaf on X of germs of S-morphisms from X to Y, defined by

$$\mathcal{H}om(X, Y)(U) = \mathrm{Hom}(U, Y)$$

for U open in X.

Let $s \in S$, and write i_s for the inclusion of X_s in X. There is a canonical induction homomorphism

$$i_s^{-1}\mathcal{H}om(X, Y) \longrightarrow \mathcal{H}om(X_s, Y_s) \tag{2.1.1}$$

which is an epimorphism, as is immediate. In the case $Y = S \times \mathbb{R}$, the sheaf $\mathcal{H}om(X, Y)$ is canonically identified with $\mathcal{O}_X$, and the epimorphism (2.1.1) with the epimorphism

$$i_s^{-1}(\mathcal{O}_X) \longrightarrow i_s^*(\mathcal{O}_X)$$

considered in (1.1).

Proposition 2.2. Let X, Y be mixed S-varieties, and let $s \in S$. Suppose that the fiber X_s is paracompact and that s has a fundamental system of paracompact neighborhoods. Let A be a closed subset of X_s, and let

$$f \in H^0(A, \mathcal{H}om(X_s, Y_s)).$$

The subsheaf $\mathcal{F}$ of $i_s^{-1}\mathcal{H}om(X, Y)$ consisting of the germs which extend f, that is, whose image by (2.1.1) coincides with f over A, is soft.

Proof. Let X' be an open neighborhood in X which is isomorphic, as a mixed variety, to $S' \times U$, where S' is a paracompact neighborhood of s and U is a relatively compact open subset of $\mathbb{R}^n$, and such that the image by f of $X'_s \cap A$ is contained in an open subset of Y isomorphic to $S' \times V$, where V is a convex open subset of $\mathbb{R}^q$ containing the origin. By T.F. II 3.4.1 it is enough to show that every section of $\mathcal{F}$ over a closed subset of X_s contained in X'_s extends to X'_s. Since $X'_s = \{s\} \times U$ is relatively compact, a closed subset of X_s contained in X'_s is compact. Identifying X' with $S' \times U$ and Y' with $S' \times V$, putting $A' = A \cap X'_s$, and using T.F. II 3.3.1, the assertion is reduced to the following elementary lemma.[17]

Lemma 2.2.1. Let U be an open subset of $\mathbb{R}^n$, and let V be a convex open subset of $\mathbb{R}^q$ containing 0. Let A_1, A_2 be closed subsets of $\{s\} \times U$. Let U_1, respectively U_2, be an open subset of $S \times U$, respectively of $\{s\} \times U$, containing A_1, respectively A_2. Let $f_1 : U_1 \to V$ be a morphism and let $f_2 : U_2 \to S \times V$ be an S-morphism which, on $U_1 \cap (\{s\} \times U)$, defines the same germ as f_1 near A_1. Then there exists an open subset U' of $S \times U$ containing $\{s\} \times U$ and an S-morphism

$$F : U' \longrightarrow S \times V$$

such that the germ of F along $\{s\} \times U$ extends the germ defined by f_1, and the morphism induced by F on $\{s\} \times U$ defines the same germ as f_2 near A_2.

Proof. Replacing f_1 by af_1, where a is a C^∞ function on U equal to 1 near A_1 and with support in U_1, one may suppose $U_1 = U$. Let b be a C^∞ function on U, equal to 1 on A_2 and with support in $U_2 \cap (\{s\} \times U)$. Then

$$U' = U_1 \cup \big(S \times (U - \mathrm{Supp}\, b)\big)$$

[17] Communicated to the writer by A. Douady. A closed subset of a paracompact space has a fundamental system of paracompact neighborhoods.

is an open subset of $S \times U$ containing $\{s\} \times U$. The morphism $F : U' \to S \times V$ defined by

$$F(t,x) = \big(t,\, b(x)\,\mathrm{pr}_2\, f_2(x) + (1 - b(x)) f_1(t,x)\big)$$

visibly satisfies the required conditions.

Corollary 2.3. Under the hypotheses of (2.2), the sheaves $i_s^{-1}\mathcal{H}om(X,Y)$ and $\mathcal{H}om(X_s,Y_s)$ are soft. In particular, the sheaves $i_s^{-1}(\mathcal{O}_X)$ and $\mathcal{O}_{X_s}$ are soft. For every closed subset A of X_s, the map

$$H^0(X_s, i_s^{-1}\mathcal{H}om(X,Y)) \longrightarrow H^0(A, \mathcal{H}om(X_s,Y_s))$$

deduced from (2.1.1) is surjective.

Proof. The softness of $i_s^{-1}\mathcal{H}om(X,Y)$ follows from (2.2) applied with $A = \varnothing$. Taking $S = \{s\}$, one obtains the softness of $\mathcal{H}om(X_s,Y_s)$. The last assertion follows from (2.2).[18]

Corollary 2.4. Under the hypotheses of (2.2), let E be an $\mathcal{O}_X$-module. For every closed subset A of X_s, the canonical homomorphism

$$H^0(X_s, i_s^{-1}E) \longrightarrow H^0(A, i_s^*E)$$

deduced from the epimorphism

$$i_s^{-1}E \longrightarrow i_s^*E = i_s^{-1}E \otimes_{i_s^{-1}\mathcal{O}_X} \mathcal{O}_{X_s}$$

is an epimorphism.

Proof. Since $i_s^{-1}\mathcal{O}_X$ is soft by (2.3), the functor $H^0(A,\ )$ is exact on the category of $i_s^{-1}\mathcal{O}_X$-modules (T.F. II 3.7.1, 3.4.2, 4.4.3). Hence

$$H^0(A, i_s^{-1}E) \longrightarrow H^0(A, i_s^*E)$$

is an epimorphism. Since $i_s^{-1}E$ is soft, the homomorphism

$$H^0(X_s, i_s^{-1}E) \longrightarrow H^0(A, i_s^{-1}E)$$

is an epimorphism, and this proves the assertion.

Corollary 2.5. Let $p : X \to S$ be a mixed variety and let $s \in S$. Suppose that s has a fundamental system of paracompact neighborhoods S' such that the $p^{-1}(S')$ form a fundamental system of paracompact neighborhoods of X_s. This condition is satisfied, for example, if S is locally compact and p is a proper map of topological spaces. Then, for every $\mathcal{O}_X$-module E,

$$(R^i p_* E)_s = 0 \qquad (i > 0).$$

Proof. By T.F. II 4.17.1,

$$(R^i p_* E)_s = H^i(X_s, i_s^{-1}E).$$

But $i_s^{-1}\mathcal{O}_X$ is soft by (2.3), hence $H^i(X_s, i_s^{-1}E) = 0$ for $i > 0$.

Corollary 2.6. Let X, Y be mixed S-varieties, and let $s \in S$. Suppose that X satisfies the hypotheses of (2.5). For every morphism $f : X_s \to Y_s$, there exists an open neighborhood S' of s and a morphism

$$F : X|S' \longrightarrow Y|S'$$

such that $F_s = f$.

[18] For $\mathcal{O}_{X_s}$ this is very well known. The writer does not know whether $\mathcal{O}_X$ is soft when the hypotheses of (2.2) are satisfied for every $s \in S$ and X is paracompact. This would trivially imply, under those hypotheses, the softness of $i_s^{-1}(\mathcal{O}_X)$ as well as (2.5) below.

Proof. This is an immediate consequence of (2.3), with $A = X_s$, and of the fact that the hypotheses on X give

$$H^0(X_s, i_s^{-1}\mathcal{H}om(X,Y)) = \varinjlim_{S' \ni s} \mathrm{Hom}(X|S', Y|S')$$

for open S' containing s (T.F. II 8.5.5).

Proposition 2.7. Let X, Y be mixed S-varieties, let $f : X \to Y$ be a morphism, let $s \in S$, and let $x \in X_s$. If the tangent linear map of

$$f_s : X_s \longrightarrow Y_s$$

is invertible at x, then f is a local isomorphism at x; that is, there is an open neighborhood U of x in X and an open subset V of Y such that f induces an isomorphism $U \simeq V$.

Proof. This is an easy consequence of the implicit function theorem. The details are left to the reader.

Corollary 2.8. Let X, Y be mixed S-varieties and let $s \in S$. Suppose that s has a fundamental system of neighborhoods S' such that the $X|S'$, respectively $Y|S'$, form a fundamental system of neighborhoods of X_s, respectively Y_s; this is the case, for example, if S is locally compact and X, respectively Y, is proper over S. Let $f : X \to Y$ be an S-morphism such that

$$f_s : X_s \longrightarrow Y_s$$

is an isomorphism. Then there exists a neighborhood S' of s such that

$$f|X|S' : X|S' \longrightarrow Y|S'$$

is an isomorphism.

Proof. By (2.7), there exists an open neighborhood U of X_s in X such that $f|U$ is étale, that is, a local isomorphism. We may suppose that $U = X|S'$ for a neighborhood S' of s; after shrinking S, we may therefore assume that f is étale. Then the fiber product $Z = X \times_Y X$ is naturally a mixed S-variety, étale over X for each projection, and the diagonal morphism $\Delta : X \to Z$ is an open immersion. Moreover the sets $Z|S'$ form a fundamental system of neighborhoods of Z_s. Since

$$\Delta_s : X_s \longrightarrow Z_s$$

is an isomorphism, it follows, after shrinking S, that Δ is an isomorphism. Thus f is an open immersion, and after shrinking S again it is an isomorphism.

Corollary 2.9. Let X be a mixed S-variety and let $s \in S$. Suppose that the hypothesis of (2.5) is satisfied. Then there exists a neighborhood S' of s in S such that $X|S'$ is S'-isomorphic to $S' \times X_s$.

Proof. Apply (2.6) and (2.8).

Corollary 2.10. Let $s \in S$ and let V be a paracompact variety. Put $X = S \times V$, and let i_s be the injection of V into X defined by s. Suppose that the hypothesis of (2.5) is satisfied. Let E be a locally free $\mathcal{O}_X$-module, respectively $\mathcal{O}_X \otimes \mathbb{C}$-module, of finite type. Then there exists a neighborhood S' of s in S such that $E|X|S'$ is isomorphic to $\mathrm{pr}_2^*(i_s^*E)$, where $\mathrm{pr}_2 : S' \times V \to V$ is the second projection.

Proof. Put $F = \mathrm{pr}_2^*(i_s^*E)$. By (2.4), applied to $\mathcal{H}om(E,F)$, the induction homomorphism

$$\mathrm{Hom}(i_s^{-1}E, i_s^{-1}F) \longrightarrow \mathrm{Hom}(i_s^*E, i_s^*F)$$

is an epimorphism. On the other hand, by T.F. II 3.3.1,

$$\mathrm{Hom}(i_s^{-1}E, i_s^{-1}F) = \lim_{S' \ni s} \mathrm{Hom}(E|X|S', F|X|S').$$

Thus the canonical isomorphism $i_s^*E \simeq i_s^*F$ is induced, after shrinking S, by a homomorphism $f : E \to F$. Since f_s is an isomorphism, f is an isomorphism near X_s by Nakayama, hence over $X|S'$ for a suitable neighborhood S' of s.

3. The finiteness theorem

3.0. Conventions and notation

3.0.1. Let X and Y be topological spaces. We write $C(X, Y)$ for the set of continuous maps from X to Y, and $\mathcal{C}(X, Y)$ for the sheaf on X defined by $U \mapsto C(U, Y)$.

3.0.2. Let E, F be Banach spaces, real or complex. We write $L(E, F)$ for the Banach space of continuous linear maps from E to F.

3.0.3. The mixed varieties occurring in this section are assumed to be of class C^∞. If X is a mixed S-variety, we shall often identify a locally free $\mathcal{O}_X$-module, respectively $\mathcal{O}_X \otimes \mathbb{C}$-module, of finite type with the corresponding real, respectively complex, vector bundle.

3.0.4. Let X be a compact ordinary variety, and let E be a real or complex vector bundle of finite rank on X. Write $C^\infty(X, E)$ for the Fréchet space of C^∞ sections of E on X. For $r \in \mathbb{Z}$, write $C_r(X, E)$ for the Hilbert space of sections of E which are r times differentiable in L^2 ([16] IX). For $s \leq r$, $C_r(X, E)$ maps to $C_s(X, E)$ by a continuous linear injective map with dense image, and

$$C^\infty(X, E) = \lim_r C_r(X, E).$$

3.0.5. Let S be a topological space. We shall need the notion of a Hilbert bundle over S, for which we refer the reader to [12] or [14]. There is an additive functor from the category of real, respectively complex, Hilbert bundles over S to the category of $\mathcal{O}_S$-, respectively $\mathcal{O}_S \otimes \mathbb{C}$-, modules: it sends a Hilbert bundle E to the sheaf of continuous sections of E.

3.1. Auxiliary technical results

Lemma 3.1.1. Let X, Y be topological spaces, with X locally compact. Let $\mathcal{C}'(X, Y)$ be the presheaf, on the basis of relatively compact open subsets of X, defined by

$$\mathcal{C}'(X, Y)(U) = C(\overline{U}, Y).$$

The canonical restriction morphism

$$\mathcal{C}'(X, Y) \longrightarrow \mathcal{C}(X, Y)$$

induces an isomorphism on the associated sheaves.

Proof. Immediate.

Lemma 3.1.2. Let E, F be locally convex topological vector spaces over $\mathbb{C}$, and let $u : E \to F$ be a continuous linear map, respectively a continuous linear map with dense image. Let X be compact. Endow $C(X, E)$ and $C(X, F)$ with the topology of uniform convergence. Then the induced linear map

$$u_X : C(X, E) \longrightarrow C(X, F)$$

is continuous, respectively continuous with dense image.

Proof. It is clear that u_X is continuous. On the other hand, by Bourbaki, *Intégration*, chapter II, §2, lemmas 1 and 2, the subspace $C(X,\mathbb{C})\otimes E$ of $C(X,E)$, formed by the continuous maps from X to E whose values lie in a finite-dimensional vector subspace, is dense; and similarly $C(X,\mathbb{C})\otimes F$ is dense in $C(X,F)$. If u has dense image, then $u_X(C(X,E))$ is dense in $C(X,\mathbb{C})\otimes F$, and taking closures gives the assertion.

3.1.3. Let V be a compact variety, let E and F be complex vector bundles of finite rank on V, and let $n\in\mathbb{N}$. The space $\mathrm{Diff}^n_{\mathbb{C}}(E,F)$, identified by (1.2.3.1) with

$$\mathrm{Hom}(P^n(E),F)\simeq C^\infty(V,\mathrm{Hom}(P^n(E),F)),$$

is naturally a Fréchet space. Let $u\in\mathrm{Diff}^n_{\mathbb{C}}(E,F)$. One checks easily that the linear map $C^\infty(V,E)\to C^\infty(V,F)$ defined by u is continuous. If $L(C^\infty(V,E),C^\infty(V,F))$ denotes the space of continuous linear maps, one therefore has a linear map

$$\delta:\mathrm{Diff}^n_{\mathbb{C}}(E,F)\longrightarrow L(C^\infty(V,E),C^\infty(V,F)).$$

Moreover, for $r\in\mathbb{Z}$, u acts by extension of scalars on the C_r sections of E and defines a linear map

$$\delta_r:\mathrm{Diff}^n_{\mathbb{C}}(E,F)\longrightarrow L(C_r(V,E),C_{r-n}(V,F)).$$

The maps δ_r are continuous, and for $u\in\mathrm{Diff}^n_{\mathbb{C}}(E,F)$, $\delta(u)$ is the inverse-limit element of the projective system of the $\delta_r(u)$. These assertions follow easily from [16] IX: one reduces immediately to $n=0$; the statement on the C_r follows directly from the definitions, while the statement for C^∞ follows, after localizing by a partition of unity, from the formula for successive derivatives of a product. The analogous real statements are also valid.

Lemma 3.1.4. Let S be a topological space, let V be a compact variety, let E,F be complex vector bundles of finite rank on V, and let $n\in\mathbb{N}$. Put $X=S\times V$. For

$$u\in\mathrm{Diff}^n_{\mathbb{C}}(\mathrm{pr}_2^*E,\mathrm{pr}_2^*F),$$

the map $s\mapsto i_s^*u$ from S into $\mathrm{Diff}^n_{\mathbb{C}}(E,F)$ is continuous. The linear map

$$\mathrm{Diff}^n_{\mathbb{C}}(\mathrm{pr}_2^*E,\mathrm{pr}_2^*F)\longrightarrow C(S,\mathrm{Diff}^n_{\mathbb{C}}(E,F))$$

so defined is an isomorphism.

Proof. By (1.2.3.1) one may restrict to the case $n=0$. Putting $G=\mathrm{Hom}(E,F)$, one is reduced to showing that for $u\in\Gamma(X,\mathrm{pr}_2^*G)$, the map $s\mapsto u_s=i_s^*u$ from S into $C^\infty(V,G)$ is continuous and that the resulting map

$$\Gamma(X,\mathrm{pr}_2^*G)\longrightarrow C(S,C^\infty(V,G))$$

is an isomorphism. This follows immediately from the definition of mixed varieties.

3.1.5. Under the hypotheses of (3.1.4), let

$$u\in\mathrm{Diff}^n_{\mathbb{C}}(\mathrm{pr}_2^*E,\mathrm{pr}_2^*F).$$

Identifying u, by (3.1.4), with a continuous map from S into $\mathrm{Diff}^n(E,F)$, one sees that, for U open in S, the morphism

$$\mathrm{pr}_{1*}(u)(U):C^\infty(U,E)\longrightarrow C^\infty(U,F)$$

is canonically identified with the linear map

$$C(U,C^\infty(V,E))\longrightarrow C(U,C^\infty(V,F))$$

deduced from

$$\delta u : U \longrightarrow L(C^\infty(V,E), C^\infty(V,F)).$$

Suppose S locally compact. By (3.1.1), the morphism of sheaves

$$\mathrm{pr}_{1*}(u) : \mathrm{pr}_{1*}\,\mathrm{pr}_2^*\,E \longrightarrow \mathrm{pr}_{1*}\,\mathrm{pr}_2^*\,F$$

is the morphism associated to the morphism of presheaves

$$\mathcal{C}'(S, C^\infty(V,E)) \longrightarrow \mathcal{C}'(S, C^\infty(V,F))$$

defined by δu. On the other hand, for $r \in \mathbb{Z}$,

$$\delta_r u : S \longrightarrow L(C_r(V,E), C_{r-n}(V,F))$$

defines a morphism of presheaves

$$u_r : \mathcal{C}'(S, C_r(V,E)) \longrightarrow \mathcal{C}'(S, C_{r-n}(V,F)).$$

By (3.1.3), the u_r form a projective system whose limit is the previous morphism. It will be convenient to interpret $\delta_r u$ as a morphism of trivial Hilbert bundles

$$S \times C_r(V,E) \longrightarrow S \times C_{r-n}(V,F),$$

inducing on sheaves of sections the sheaf morphism associated to u_r.

3.2. Definition of the index

Theorem 3.2.1. Let S be a locally compact space, let $p : X \to S$ be a proper mixed variety, and let $E^\bullet$ be an elliptic complex of order (n_i) of complex vector bundles on X (1.2.5). Then the complex $Rp_*(E^\bullet)$, which by (2.5) is isomorphic to $p_*(E^\bullet)$ in the derived category of $\mathcal{O}_S \otimes \mathbb{C}$-modules, is perfect.

Proof. The question being local on S, one may suppose by (2.9) that $X = S \times V$, where V is a compact variety, and that $p = \mathrm{pr}_1$. Moreover, by (2.10), one may suppose that for all i,

$$E^i = \mathrm{pr}_2^*(F^i),$$

where F^i is a complex vector bundle of finite rank on V. By (3.1.5), $p_*(E^\bullet)$ is associated to the complex of presheaves

$$\mathcal{C}'(S, C^\infty(V, F^\bullet)),$$

where the differentials are induced by the given differential operators. Put, for each $i \in \mathbb{Z}$,

$$m_i = \sum_{j<i} n_j,$$

with the convention $n_i = 0$ if $E^i = 0$. For each $r \in \mathbb{Z}$ one has, again by (3.1.5), a complex of presheaves

$$\mathcal{C}'(S, C_{r-m_i}(V, F^i)),$$

which we denote by $\mathcal{C}'(S, C_r(V, F^\bullet))$. These complexes form a projective system, and

$$\mathcal{C}'(S, C^\infty(V, F^\bullet)) = \lim_r \mathcal{C}'(S, C_r(V, F^\bullet)). \tag{3.2.1.1}$$

Finally, denote by $F_r^\bullet$ the complex of trivial Hilbert bundles over S defined by the corresponding $\delta_r(d^i)$, and by $\mathcal{F}_r^\bullet$ the complex of sheaves of sections; by (3.1.5), it is just the complex of

sheaves associated to $\mathcal{C}'(S, C_r(V, F^\bullet))$. To prove the theorem it is enough to prove the following assertions:

(a) For $r \in \mathbb{Z}$, the canonical morphism

$$\mathcal{C}'(S, C^\infty(V, F^\bullet)) \longrightarrow \mathcal{C}'(S, C_r(V, F^\bullet))$$

is a quasi-isomorphism of complexes of presheaves, that is, it induces isomorphisms on the presheaves of cohomology.

(b) For $r \in \mathbb{Z}$, the complex $\mathcal{F}_r^\bullet$ is perfect.

Proof of (b). The ellipticity of $E^\bullet$ implies ([16] XI, theorem 6) that, for every $s \in S$, the differential of $(F_r^\bullet)_s$ has closed image and the spaces $H^i((F_r^\bullet)_s)$ are finite-dimensional vector spaces. In the terminology of [11], $F_r^\bullet$ is a direct quasi-acyclic complex of Hilbert bundles. Hence, by [12] 2.3, $F_r^\bullet$ is locally homotopically equivalent to a bounded complex of vector bundles of finite rank. Since the sheaf-of-sections functor is additive (3.0.5), $\mathcal{F}_r^\bullet$ is locally homotopically equivalent to a bounded complex of locally free sheaves of finite type; hence it is perfect.

For the proof of (a) we shall need the following intermediate assertion:

(a') For $p \gg q$, the canonical morphism

$$F_p^\bullet \longrightarrow F_q^\bullet$$

is a quasi-isomorphism.

Proof of (a'). Let $M_{pq}^\bullet$ be the complex of Hilbert bundles which is the cone of the morphism $F_p^\bullet \to F_q^\bullet$. The ellipticity of $E^\bullet$ implies that, for every $s \in S$, the morphism $(F_p^\bullet)_s \to (F_q^\bullet)_s$ is a quasi-isomorphism ([16] XI, corollary 2 and theorem 6). In other words, $(M_{pq}^\bullet)_s$ is a direct acyclic complex. By [11] 2.3, $M_{pq}^\bullet$ is locally homotopically trivial; hence its sheaf complex, the cone of $\mathcal{F}_p^\bullet \to \mathcal{F}_q^\bullet$, is acyclic.

Proof of (a). It is enough to show that, for every relatively compact open subset U of S, the morphism

$$C^\infty(U, C^\infty(V, F^\bullet)) \longrightarrow C^\infty(U, C_r(V, F^\bullet))$$

is a quasi-isomorphism. Replacing S by $\overline{U}$ and $E^\bullet$ by the induced complex over $\overline{U}$, one is reduced to proving that

$$C(S, C^\infty(V, F^\bullet)) \longrightarrow C(S, C_r(V, F^\bullet))$$

is a quasi-isomorphism, with S compact. By (3.2.1.1),

$$C(S, C^\infty(V, F^\bullet)) = \lim_i C(S, C_i(V, F^\bullet)).$$

For each i, $C(S, C_i(V, F^j))$ is a Banach space for the topology of uniform convergence, and the transition morphisms

$$C(S, C_i(V, F^j)) \longrightarrow C(S, C_{i-1}(V, F^j))$$

are continuous linear maps with dense image by (3.0.4) and (3.1.2). On the other hand, applying to the quasi-isomorphisms (a') the functor "sections", which is exact since $\mathcal{O}_S$ is soft, one sees that the transition morphisms are quasi-isomorphisms. Assertion (a) follows from EGA 0_{I} 13.2.3, topological variant. This completes the proof of (3.2.1).

3.2.2. If S is a topological space, we denote by $\mathrm{Parf}(S)$ the triangulated category of perfect complexes of $(\mathcal{O}_S \otimes \mathbb{C})$-modules, and by $K^0(S)$ the corresponding Grothendieck group.[19]

[19] See I 6.3. For a general review of K-functors, see Exposé IV.

Let $S, X, E^\bullet$ be as in (3.2.1). The *analytic index* of $E^\bullet$ is the element

$$\mathrm{ind}_{\mathrm{an}}(E^\bullet) = [Rp_*(E^\bullet)] \in K^0(S).$$

If S is compact, $\mathrm{ind}_{\mathrm{an}}(E^\bullet)$ canonically defines an element in the usual group $K(S)$ of topologists. Indeed, in general, for every topological space S, let $\mathrm{Loclib}(S)$ be the additive category of locally free $(\mathcal{O}_S \otimes \mathbb{C})$-modules of finite type, and let $K(S)$ be the Grothendieck group of the triangulated category

$$K^b(\mathrm{Loclib}(S))/K^b_{\mathrm{ac}}(\mathrm{Loclib}(S)).$$

This category is in fact identified with $K^b(\mathrm{Loclib}(S))$ when S is paracompact (II 2.2.2(a)), so in this case, by I 6.4, $K(S)$ is canonically isomorphic to the Grothendieck group of the additive category $\mathrm{Loclib}(S)$. There is a natural homomorphism

$$K(S) \longrightarrow K^0(S).$$

By II 2.3.2 this is an isomorphism for compact S, proving the assertion. More generally, $\mathrm{ind}_{\mathrm{an}}(E^\bullet)$ defines an element in the completed group

$$\widehat{K}(S) = \lim_A K(A),$$

the projective limit being taken over the compact subsets A of S.

3.2.3. The writer does not know whether the finiteness theorem (3.2.1) remains valid if, instead of assuming S locally compact, one merely assumes that each point of S has a fundamental system of paracompact neighborhoods. Moreover, the local compactness hypothesis on S does not seem very natural. The space of "universal local parameters" for elliptic complexes of fixed order is in fact a subspace of infinite dimension in a Fréchet space. More precisely, let V be a compact variety, let $F = (F^i)$ be a sequence of complex vector bundles of finite rank on V, zero except for finitely many indices, and let $n = (n_i)$ be a sequence of integers ≥ 0. Let $\mathrm{Comp.\,diff}_n(F)$ be the space of complexes of differential operators of base F and order n, that is, the closed subspace of

$$\prod_i \mathrm{Diff}^{n_i}(F^i, F^{i+1})$$

defined by the equations $d^{i+1}d^i = 0$. This product is a Fréchet space. The subset $\mathrm{Ell}_n(F)$ formed by the elliptic complexes of order n is open. It is this space, in general not locally compact, which plays the role of a space of universal local parameters.

3.2.4. Nevertheless, even if the generalization of (3.2.1) just mentioned is impossible, one can always associate to $E^\bullet$, under the sole hypothesis that the fibration p is proper and locally trivial, an element of $K^0(S)$ deserving the name analytic index of $E^\bullet$. Indeed, suppose, for simplicity, that we are in the local situation where $X = S \times V$ with V compact, and $E^\bullet$ is given by a continuous map from S into $\mathrm{Ell}_n(F)$ (3.2.3). Assertions (a') and (b) in the proof of (3.2.1) are in fact valid without any hypothesis on S; it is therefore reasonable to put, with the notation of that proof,

$$\mathrm{ind}_{\mathrm{an}}(E^\bullet) = [\mathcal{F}_r^\bullet] \in K^0(S),$$

this element being independent of r.

3.2.5. Suppose S paracompact. Let H be a complex Hilbert space of infinite Hilbert dimension, and let $I(H)$ be the subspace of $L(H, H)$ formed by the Fredholm operators. The complexes $F_r^\bullet$ define [12] a canonical element in the group $[S, I(H)]$ of homotopy classes of continuous maps from S to $I(H)$. But the writer does not know, for non-compact S (even when S is locally compact), what the relations are between $[S, I(H)]$ and $K^0(S)$: is there a natural arrow from

one to the other? are they isomorphic? A fortiori, the relation between the two indices thus defined remains unclear.

For a generalization, under the hypotheses of (3.2.1), of the Atiyah–Singer index theorem, we refer to the recent work of Shih [17], or to work in preparation of M. F. Atiyah and I. M. Singer.[20]

Exposé III. Relative finiteness conditions

by L. Illusie

1. Relative pseudo-coherence

Theorem 1.1. Let $n \in \mathbb{Z}$. For each locally finite type morphism of schemes

$$f : X \longrightarrow Y$$

there exists one and only one full subcategory $D(f)_{n\text{-coh}}$ of $D(X)$ such that the following conditions are satisfied:

(i) If $E \in \operatorname{ob} D(f)_{n\text{-coh}}$, then $i^*(E) \in \operatorname{ob} D(fi)_{n\text{-coh}}$ for every open immersion $i : U \to X$.

(ii) If $E \in \operatorname{ob} D(X)$, and if there exists an open covering $(i_\alpha : U_\alpha \to X)_{\alpha \in A}$ such that $i_\alpha^*(E) \in \operatorname{ob} D(fi_\alpha)_{n\text{-coh}}$ for every $\alpha \in A$, then $E \in \operatorname{ob} D(f)_{n\text{-coh}}$.

(iii) If

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & \searrow^{h} & \downarrow{\scriptstyle g} \\ & & Z \end{array}$$

is a commutative triangle of locally finite type morphisms, where f is a closed immersion and g is smooth, then one has

$$E \in \operatorname{ob} D(h)_{n\text{-coh}} \quad \Longleftrightarrow \quad f_*(E) \in D(Y)_{n\text{-coh}}.$$

Here $D(X)$ denotes the derived category of $\mathcal{O}_X$-modules, and $D(Y)_{n\text{-coh}}$ denotes the full subcategory of $D(Y)$ formed by the n-pseudo-coherent objects.

Proof. Uniqueness is evident. Let indeed $f : X \to Y$ be a locally finite type morphism. Choose an open covering $(i_\alpha : X_\alpha \to X)_{\alpha \in A}$ such that, for every α, fi_α factors as

$$X_\alpha \xrightarrow{i'_\alpha} Y_\alpha \xrightarrow{f'_\alpha} Y,$$

where i'_α is a closed immersion and f'_α is smooth. It follows at once from (i), (ii), (iii) that the objects of $D(f)_{n\text{-coh}}$ are precisely the objects $E \in D(X)$ such that

$$i'_{\alpha *} i_\alpha^*(E) \in \operatorname{ob} D(Y_\alpha)_{n\text{-coh}};$$

therefore $D(f)_{n\text{-coh}}$ is well determined, since it is a full subcategory of $D(X)$. To prove existence we shall need several lemmas.

Lemma 1.1.1. Let $i : X \to Y$ be a closed immersion of schemes such that $i_*(\mathcal{O}_X)$ is pseudo-coherent, and let $E \in \operatorname{ob} D(X)$. In order that E be n-pseudo-coherent, it is necessary and sufficient that $i_*(E)$ be so.

Proof. The necessity follows from the general stability criterion for pseudo-coherence under application of a functor. Conversely, suppose that $i_*(E)$ is n-pseudo-coherent, and prove that the same is true of E. Since $i_*(E)$ has locally bounded-above cohomology, the same is true of E. The question being local, one may suppose that E is m-pseudo-coherent for m sufficiently large. We prove by descending induction on m, with E assumed m-pseudo-coherent for some

$m \geq n$. Suppose already proved that E is $(n+1)$-pseudo-coherent. After localization, there is a distinguished triangle

$$E' \longrightarrow E \longrightarrow E'' \longrightarrow E'[1]$$

where E' is perfect and $H^i(E'') = 0$ for $i > n$. By Exposé I, Proposition 2.6, it remains to show that E'' is n-pseudo-coherent. Applying i_* to the preceding triangle, we get a distinguished triangle

$$i_*(E') \longrightarrow i_*(E) \longrightarrow i_*(E'') \longrightarrow i_*(E')[1]$$

and, by the first part of the proof, $i_*(E')$ is pseudo-coherent. Hence, again by Exposé I, Proposition 2.6, $i_*(E'')$ is n-pseudo-coherent. Since $i_*(E'')$ is zero in degrees $> n$, this means, by Exposé I, Proposition 2.10 b), that $H^n(i_*(E''))$ is of finite type. But

$$H^n(i_*(E'')) = i_* H^n(E''),$$

so the assertion is reduced to showing, by Exposé I, Proposition 2.10 b), that if M is an $\mathcal{O}_X$-module such that $i_*(M)$ is of finite type, then M is of finite type. This is immediate and independent of the hypothesis on $i_*(\mathcal{O}_X)$.

Remark 1.1.2. The preceding lemma applies in particular to the case where i is a regular immersion. Indeed, by means of the Koszul complex, $i_*(\mathcal{O}_X)$ has locally a finite left resolution by finite-type free $\mathcal{O}_Y$-modules; hence $i_*(\mathcal{O}_X)$ is perfect, and a fortiori pseudo-coherent.

Lemma 1.1.3. Let

$$\begin{array}{ccc} X' & \xrightarrow{f} & X \\ {\scriptstyle i'}\downarrow & & \downarrow{\scriptstyle i} \\ Y' & \xrightarrow[g]{} & Y \end{array}$$

be a Cartesian square of schemes, where i is a closed immersion, and let E be a complex of $\mathcal{O}_X$-modules. Then the canonical base-change arrow

$$g^* i_*(E) \longrightarrow i'_* f^*(E)$$

is an isomorphism.

If $E' = f^*(E)$, if g is flat and $i_*(E)$ is n-pseudo-coherent, then $i'_*(E')$ is n-pseudo-coherent. Conversely, if g is faithfully flat and $i'_*(E')$ is n-pseudo-coherent, then $i_*(E)$ is n-pseudo-coherent.

Proof. The assertion is verified trivially on the fibers.

Lemma 1.1.4. Let

$$\begin{array}{ccccc} X' & \xleftarrow{i'} & X & \xrightarrow{i''} & X'' \\ & {\scriptstyle f'}\nwarrow & & \nearrow{\scriptstyle f''} & \\ & & Y & & \end{array}$$

be a commutative diagram of schemes, where i' (respectively i'') is a closed immersion and f' (respectively f'') is smooth, and let $E \in \operatorname{ob} D(X)$. Then

$$i'^*(E) \text{ is } n\text{-pseudo-coherent} \quad \Longleftrightarrow \quad i''^*(E) \text{ is } n\text{-pseudo-coherent}.$$

Proof. Following a device due to Lichtenbaum, send X diagonally into $X' \times_Y X''$. One is at once reduced to proving the assertion in the case where one of the morphisms f', f'' is the identity. Changing notation, one has a commutative triangle

$$\begin{array}{ccc} & & Y \\ & {\scriptstyle j}\nearrow & \downarrow{\scriptstyle f} \\ X & \xrightarrow[i]{} & Z \end{array}$$

where i and j are closed immersions and f is smooth, and one must show that $i_*(E)$ is n-pseudo-coherent if and only if $j_*(E)$ is n-pseudo-coherent. The question being local on Y and on Z in a neighborhood of a point of X, one may suppose that X, Y, Z are affine and that there is a factorization

$$\begin{array}{ccc} Y & \xrightarrow{i'} & Z[T_1, \ldots, T_r] \\ {\scriptstyle f}\downarrow & \swarrow & \\ Z & & \end{array}$$

where i' is a closed immersion and the oblique arrow is the canonical projection. Then, by Exposé VII, 1.10, i' is a regular immersion; hence by Lemma 1.1.1 an object F of $D(Y)$ is n-pseudo-coherent if and only if $i'_*(F)$ is so.

Thus one may suppose that $Y = Z[T_1, \ldots, T_r]$, f being the canonical projection. The preceding diagram then corresponds to a diagram of rings

$$A \xleftarrow{v} C \xrightarrow{u} B = C[T_1, \ldots, T_r]$$

where u and v are epimorphisms and $c : C \to B$ is the canonical inclusion. For $1 \leq i \leq r$, put $u(T_i) = x_i$, and let $z_i \in C$ be such that $v(z_i) = x_i$. The retraction

$$\sigma : B \longrightarrow C, \qquad \sigma(T_i) = z_i,$$

is defined by $c(T_i) = z_i$, is such that $v\sigma = u$. Geometrically, it corresponds to a section s of f such that $i = sj$. By Exposé VII, 1.10, s is a regular immersion; the assertion therefore follows from Lemma 1.1.1.

End of the proof of Theorem 1.1. Let $f : X \to Y$ be a locally finite type morphism. There exists an open covering (X_α) of X such that each X_α embeds by a closed immersion into a scheme Y_α smooth over Y. Put $\coprod X_\alpha = X'$, $\coprod Y_\alpha = Y'$. We have a commutative diagram

$$\begin{array}{ccc} X' & \xrightarrow{i'} & Y' \\ {\scriptstyle p'}\downarrow & \swarrow_{f'} & \\ X & & \\ {\scriptstyle f}\downarrow & & \\ Y & & \end{array}$$

where p' is the morphism which is the sum of a surjective family of open immersions (we shall say *special*, for short), i' is a closed immersion, and f' is smooth. We define $D(f)_{n\text{-coh}}$ as the full subcategory of $D(X)$ formed by the objects E such that $i'_* p'^*(E)$ is n-pseudo-coherent. First we show that this definition makes sense, that is, that $D(f)_{n\text{-coh}}$ is independent of the choice of i', p', f'. Let

$$\begin{array}{ccc} X'' & \xrightarrow{i''} & Y'' \\ {\scriptstyle p''}\downarrow & \swarrow_{f''} & \\ X & & \\ {\scriptstyle f}\downarrow & & \\ Y & & \end{array}$$

be an analogous commutative diagram, with p'' special, i'' a closed immersion, and f'' smooth.

From the two diagrams one deduces a commutative diagram

$$\begin{array}{ccc}
X' \times_X X'' & \longrightarrow & Y' \times_Y Y'' \\
\downarrow & & \downarrow \\
X' & \xrightarrow{i'} & Y' \\
\downarrow & & \downarrow{\scriptstyle f'} \\
X'' & \xrightarrow[i'']{} & Y'' \\
\downarrow & & {\scriptstyle f''}\downarrow \\
X & \xrightarrow[f]{} & Y
\end{array}$$

where the horizontal arrows, except for f, are closed immersions, and the arrows of the left (respectively right) Cartesian square are special morphisms (respectively smooth morphisms). Thus one is reduced to proving the following assertion.

$$\begin{array}{ccc}
X_1 & \xrightarrow{i_1} & Y_1 \\
{\scriptstyle p}\downarrow & & \downarrow{\scriptstyle q} \\
X_2 & \xrightarrow[i_2]{} & Y_2
\end{array}$$

Let this be a commutative square of schemes, where p is special, q is smooth, i_1 and i_2 are closed immersions, and let $E \in \operatorname{ob} D(X_2)$. Then $i_{2*}(E)$ is n-pseudo-coherent if and only if $i_{1*}p^*(E)$ is so.

Proof of the assertion. By definition, p is the sum of a family of opens U_α of X_2 covering X_2. Each U_α is induced by an open V_α of Y_2, and the V_α cover an open neighborhood X_2' of X_2 in Y_2. There is therefore a Cartesian commutative diagram

$$\begin{array}{ccccc}
X_1 & \xrightarrow{i_1'} & X_1' & & \\
{\scriptstyle p}\downarrow & & \downarrow{\scriptstyle p'} & & \\
X_2 & \xrightarrow[i_2']{} & X_2' & \xrightarrow[j]{} & Y_2
\end{array}$$

where i_1' and i_2' are closed immersions, p and p' are special morphisms, and j is an open immersion. The condition that $i_{2*}(E)$ be n-pseudo-coherent is plainly equivalent to the condition that $i'_{2*}(E)$ be n-pseudo-coherent. On the other hand, by Lemma 1.1.3, the condition that $i'_{2*}(E)$ be n-pseudo-coherent is equivalent to the condition that $i'_{1*}p^*(E)$ be n-pseudo-coherent. Applying Lemma 1.1.4 to the factorizations $(jp')i_1'$ and qi_1 of i_2p, and to $p^*(E) \in \operatorname{ob} D(X_1)$, one finally concludes that $i'_{2*}(E)$ is n-pseudo-coherent if and only if $i_{1*}p^*(E)$ is n-pseudo-coherent, as required.

We have thus shown that the category $D(f)_{n\text{-coh}}$ defined above by means of a diagram as above depends in fact only on f. Moreover it is trivial from the definition that it satisfies (i) to (iii). This proves Theorem 1.1.

Definition 1.2. Let $f : X \to Y$ be a locally finite type morphism, let $E \in \operatorname{ob} D(X)$, and let $n \in \mathbb{Z}$. We say that E is n-pseudo-coherent relative to f if $E \in \operatorname{ob} D(f)_{n\text{-coh}}$ (cf. 1.1). We say that E is pseudo-coherent, or $(-\infty)$-pseudo-coherent, relative to f if E is n-pseudo-coherent relative to f for every $n \in \mathbb{Z}$. We write $D(f)_{\text{coh}}$ for the full subcategory of $D(X)$ formed by the objects pseudo-coherent relative to f.

We shall say that f is n-pseudo-coherent (respectively pseudo-coherent) if $\mathcal{O}_X$ is n-pseudo-coherent (respectively pseudo-coherent) relative to f. When this cannot lead to confusion, we

shall sometimes say "n-pseudo-coherent (respectively pseudo-coherent) relative to Y" instead of "relative to f," and we shall also write

$$D(X)_{Y,n\text{-coh}} \quad \text{(respectively } D(X)_{Y,\text{coh}}\text{)}$$

instead of

$$D(f)_{n\text{-coh}} \quad \text{(respectively } D(f)_{\text{coh}}\text{)}.$$

Finally, for $* = +, -, b$, put

$$D^*(f)_{n\text{-coh}} = D^*(X) \cap D(f)_{n\text{-coh}}, \qquad D^*(f)_{\text{coh}} = D^*(X) \cap D(f)_{\text{coh}}.$$

Remarks 1.2.1.

a) The categories $D(f)_{n\text{-coh}}$, $D(f)_{\text{coh}}$ are not in general contained in $D^-(X)$. This is the case, however, if X is quasi-compact, since an object of $D(X)$ with locally bounded-above cohomology then has bounded-above cohomology.

b) The objects of $D(f)_{\text{coh}}$ have quasi-coherent cohomology. Indeed, if $E \in \text{ob}\, D(f)_{\text{coh}}$, the question being local, one may suppose that f is a closed immersion; then $f_*(E)$ is pseudo-coherent, hence has quasi-coherent cohomology, and one uses the fact that an $\mathcal{O}_X$-module M is quasi-coherent if and only if $f_*(M)$ is.

c) When it is a matter of an $\mathcal{O}_X$-module, we shall use the terminology "of finite presentation relative to f" in preference to "(-1)-pseudo-coherent relative to f." For an $\mathcal{O}_X$-module E to be of finite presentation relative to f, it is necessary and sufficient, by Exposé I, Proposition 2.9, that there exist locally a closed immersion $i : X \to X'$, with X' smooth over Y, such that $i_*(E)$ is of finite presentation in the ordinary sense. In particular, to say that f is (-1)-pseudo-coherent is equivalent to saying that f is locally of finite presentation in the sense of EGA IV 1.4.

Examples 1.3. A smooth morphism and a regular immersion are pseudo-coherent morphisms. The same is true of an arbitrary locally finite type morphism $f : X \to Y$ if Y is locally noetherian.

Proposition 1.4. Let $f : X \to Y$ be a locally finite type morphism and let

$$E \longrightarrow F \longrightarrow G \longrightarrow E[1]$$

be a distinguished triangle of $D(X)$. The following table, where $n \in \mathbb{Z} \cup \{-\infty\}$ indicates a degree of pseudo-coherence relative to f, has the property that each line represents an implication whose conclusion is underlined:

E	F	G
$n+1$	n	$\underline{n}$
n	$\underline{n}$	n
$\underline{n}$	n	$n-1$.

In particular, $D(f)_{\text{coh}}$ is a triangulated subcategory of $D(X)$.

Proof. By the properties (i) to (iii) of Theorem 1.1, one may suppose that f is a closed immersion. We then have a distinguished triangle

$$f_*(E) \longrightarrow f_*(F) \longrightarrow f_*(G) \longrightarrow f_*(E)[1]$$

and the assertion follows from Exposé I, Proposition 2.6.

Definition 1.5. Let X and Y be two S-schemes. We shall say that X and Y are *Tor-independent over S* if

$$\text{Tor}_i^S(\mathcal{O}_X, \mathcal{O}_Y) = 0 \quad \text{for } i \neq 0,$$

where the Tor_i^S are the local hyper-Tor sheaves defined in EGA III 6.5. This is a condition of local nature. If X, Y, S are affine, with respective rings B, C, A, it means that the canonical map

$$B \otimes_A^{\mathbf{L}} C \longrightarrow B \otimes_A C$$

is an isomorphism. It is therefore satisfied in particular if X or Y is flat over S.

Lemma 1.5.1. Let

$$\begin{array}{ccccc} X & \longleftarrow & X' & \longleftarrow & X'' \\ \uparrow & & \uparrow & & \uparrow \\ Y & \longleftarrow & Y' & \longleftarrow & Y'' \end{array}$$

be Cartesian squares of schemes. If X and Y' are Tor-independent over Y, and if X' and Y'' are Tor-independent over Y', then X and Y'' are Tor-independent over Y.

Proof. This is an easy exercise on associativity of the tensor product.

Notation 1.6. Let X and Y be two S-schemes, $E \in \mathrm{ob}\, D^-(X)$, $F \in \mathrm{ob}\, D^-(Y)$. We put

$$E \otimes_S^{\mathbf{L}} F = L\,\mathrm{pr}_1^*(E) \otimes^{\mathbf{L}} L\,\mathrm{pr}_2^*(F),$$

where $\mathrm{pr}_1, \mathrm{pr}_2$ are the two projections from $X \times_S Y$.

Lemma 1.7. Let S be a scheme, and for $i = 1, 2$ let

$$f_i : X_i \longrightarrow Y_i$$

be a closed S-immersion. Suppose that X_1 and X_2, and also Y_1 and Y_2, are Tor-independent over S. Then, for $E_i \in \mathrm{ob}\, D^-(X_i)_{\mathrm{qcoh}}$, there is a canonical isomorphism

$$f_{1*}(E_1) \otimes_S^{\mathbf{L}} f_{2*}(E_2) \xrightarrow{\sim} (f_1 \times_S f_2)_*(E_1 \otimes_S^{\mathbf{L}} E_2).$$

Proof. Put $f_1 \times_S f_2 = f$. One easily defines, by adjunction, a canonical arrow

$$f_{1*}(E_1) \otimes_S^{\mathbf{L}} f_{2*}(E_2) \longrightarrow f_*(E_1 \otimes_S^{\mathbf{L}} E_2).$$

We show that it is an isomorphism. The question being local, one may suppose S, X_i, Y_i affine with respective rings C, A_i, B_i. By dévissage, one is reduced to $E_i = \mathcal{O}_{X_i}$. One must then verify that

$$A_1 \otimes_{B_1}^{\mathbf{L}} B \otimes_{B_2}^{\mathbf{L}} A_2 \longrightarrow A$$

is an isomorphism, where $A = A_1 \otimes_C A_2$, $B = B_1 \otimes_C B_2$. In view of the Tor-independence hypotheses, this follows at once from associativity of the tensor product.

Proposition 1.8. Let S be a scheme, and for $i = 1, 2$ let

$$f_i : X_i \longrightarrow Y_i$$

be a locally finite type S-morphism. Suppose that X_1 and X_2, and also Y_1 and Y_2, are Tor-independent over S. Let $[a_i, b_i]$ be intervals of $\mathbb{Z}$, and let

$$E_i \in \mathrm{ob}\, D^-(X_i)_{\mathrm{qcoh}}$$

be a complex which is a_i-pseudo-coherent relative to f_i and acyclic in degree $> b_i$. Then

$$E_1 \otimes_S^{\mathbf{L}} E_2$$

is a-pseudo-coherent relative to $f = f_1 \times_S f_2$ and acyclic in degree $> b$, where

$$a = \sup(a_1 + b_2, a_2 + b_1), \qquad b = b_1 + b_2.$$

Proof. The question being local on $X_1 \times_S X_2$, one may suppose that f_i factors as

$$X_i \xrightarrow{i_i} Y_i' \xrightarrow{p_i} Y_i,$$

where i_i is a closed immersion and p_i a smooth morphism. Put $f' = f_1' \times_S f_2'$. We must show that $f'_*(E_1 \otimes_S^{\mathbf{L}} E_2)$ is a-pseudo-coherent and acyclic in degree $> b$. By Lemma 1.5.1, Y_1' and Y_2' are Tor-independent over S. After changing notation, one may suppose that $f_i = f_i'$, in other words that the f_i are closed immersions. By hypothesis, $f_{i*}(E_i)$ is a_i-pseudo-coherent and acyclic in degree $> b_i$; hence by Exposé I, Proposition 2.16,

$$f_{1*}(E_1) \otimes_S^{\mathbf{L}} f_{2*}(E_2)$$

is a-pseudo-coherent and acyclic in degree $> b$. One concludes by Lemma 1.7.

Corollary 1.9. Under the hypotheses of Proposition 1.8, the functor

$$\otimes_S^{\mathbf{L}} : D^-(X_1) \times D^-(X_2) \longrightarrow D^-(X)$$

induces a functor

$$\otimes_S^{\mathbf{L}} : D^-(f_1)_{\mathrm{coh}} \times D^-(f_2)_{\mathrm{coh}} \longrightarrow D^-(f)_{\mathrm{coh}}.$$

In particular, if f_1 and f_2 are pseudo-coherent, then so is f.

Corollary 1.10. Let

$$\begin{array}{ccc} X' & \xrightarrow{g} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow[h]{} & Y \end{array}$$

be a Cartesian square, with f locally of finite type. Then:

a) Suppose that X and Y' are Tor-independent over Y. For $n \in \mathbb{Z} \cup \{-\infty\}$, the functor $Lg^* : D^-(X) \to D^-(X')$ induces a functor

$$Lg^* : D^-(f)_{n\text{-}\mathrm{coh}} \longrightarrow D^-(f')_{n\text{-}\mathrm{coh}}.$$

In particular, if f is n-pseudo-coherent, then so is f'.

b) Suppose that h is faithfully flat. Let $n \in \mathbb{Z} \cup \{-\infty\}$, and let $E \in \mathrm{ob}\, D^-(X)$ be a complex with quasi-coherent cohomology. In order that E be n-pseudo-coherent relative to f, it is necessary and sufficient that $g^*(E)$ be n-pseudo-coherent relative to f'. In particular, in order that f be n-pseudo-coherent, it is necessary and sufficient that f' be so.

Proof. Taking Remark 1.2.1 b) into account, all assertions of Corollaries 1.9 and 1.10 follow trivially from Proposition 1.8, except the necessity in 1.10 b). For this one may, the question being local on X, suppose that f factors as a closed immersion followed by a smooth morphism. One is then reduced by Lemma 1.1.3 to the case where f (respectively f') is the identity of X (respectively X'). The assertion then follows, by a standard dévissage, from the fact that a quasi-coherent sheaf L on X is of finite type if and only if g^*L is of finite type.

Proposition 1.11. Let

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & {\scriptstyle h}\searrow & \downarrow{\scriptstyle g} \\ & & Z \end{array}$$

be a commutative triangle of locally finite type morphisms. Let $E \in \mathrm{ob}\, D(X)$, $F \in \mathrm{ob}\, D(Y)$, and let $[a, b]$, $[c, d]$ be intervals of $\mathbb{Z}$.

a) If E is a-pseudo-coherent relative to f and acyclic in degree $> b$, and if F is c-pseudo-coherent relative to g and acyclic in degree $> d$, then

$$E \otimes^{\mathbf{L}}_{\mathcal{O}_Y} F$$

is m-pseudo-coherent relative to h and acyclic in degree $> n$, where

$$m = \sup(a+d, b+c), \qquad n = b+d.$$

b) If E is a-pseudo-coherent relative to h and acyclic in degree $> b$, and if g is $(a+1-b)$-pseudo-coherent, then E is a-pseudo-coherent relative to f.

Proof. The question being local on X, one may suppose that there is a Cartesian commutative diagram

$$\begin{array}{ccccc} X & \xrightarrow{i} & E^r_Y & \xrightarrow{j} & E^{r+s}_Z \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle p} & & \downarrow{\scriptstyle q} \\ Y & \xrightarrow{k} & E^s_Z & \longrightarrow & Z \end{array}$$

where i, j, k are closed immersions and p, q are the canonical projections of affine spaces. If F is c-pseudo-coherent relative to Z, then $k_*(F)$ is c-pseudo-coherent by Theorem 1.1 (iii), and $j_*p^*(F)$ is c-pseudo-coherent by Lemma 1.1.3. Similarly, if g is x-pseudo-coherent, then $j_*(\mathcal{O}_{E^r_Y})$ is x-pseudo-coherent. By the definition of relative pseudo-coherence, one is thus reduced to proving a) and b) when f and g are closed immersions.

Proof of a). By Theorem 1.1 (iii), one has to show the following. Suppose $f_*(E)$ is a-pseudo-coherent and acyclic in degree $> b$, and $g_*(F)$ is c-pseudo-coherent and acyclic in degree $> d$. Then

$$h_*(E \otimes^{\mathbf{L}}_Y F)$$

is m-pseudo-coherent and acyclic in degree $> n$. There is a canonical isomorphism

$$f_*(E) \otimes^{\mathbf{L}}_Y F \xrightarrow{\sim} f_*(E \otimes^{\mathbf{L}}_Y F),$$

a special case of the isomorphism used in the proof of Proposition 1.8. Since the functor $g_*(- \otimes^{\mathbf{L}} F)$ takes finite-type locally free sheaves to c-pseudo-coherent complexes, and complexes acyclic in degree > 0 to complexes acyclic in degree $> d$, the assertion follows from Exposé I, Proposition 2.13.

Proof of b). One must prove the following assertion: suppose $f_*(E)$ is a-pseudo-coherent and acyclic in degree $> b$, and $g_*(\mathcal{O}_Y)$ is $(a+1-b)$-pseudo-coherent. Then $f_*(E)$ is a-pseudo-coherent. Since the assertion concerns $f_*(E)$, one may suppose $X = Y$ and $f = \mathrm{Id}_X$. One then proceeds as in the proof of Lemma 1.1.1, proving by descending induction that E is pseudo-coherent in degree a. Suppose already proved that E is $(a+1)$-pseudo-coherent. By Exposé I, Proposition 2.10, after localizing there is a distinguished triangle

$$E' \longrightarrow E \longrightarrow E'' \longrightarrow E'[1]$$

where E'^i is locally free for $i \in [a+1, b]$, $E'^i = 0$ for $i \notin [a+1, b]$, and $E''^i = 0$ for $i > a$. The hypothesis that $g_*(\mathcal{O}_Y)$ is $(a+1-b)$-pseudo-coherent implies, by Exposé I, Proposition 2.11 a), that $g_*(E')$ is $(a+1)$-pseudo-coherent. Since $g_*(E)$ is a-pseudo-coherent, it follows from Exposé I, Proposition 2.6, that $g_*(E'')$ is a-pseudo-coherent. We conclude by Exposé I, Proposition 2.10 b), and by the fact that an $\mathcal{O}_Y$-module M is of finite type if and only if $g_*(M)$ is. Corollaries 1.12–1.14 follow immediately.

Corollary 1.12. In the situation of Proposition 1.11, if g is pseudo-coherent, then, for $r \in \mathbb{Z} \cup \{-\infty\}$,

$$D(f)_{r\text{-coh}} = D(h)_{r\text{-coh}}.$$

In particular, taking $X = Y$, the notions of r-pseudo-coherence over Y, in the absolute sense or relative to g, coincide.

Corollary 1.13. In the situation of Proposition 1.11, if f is pseudo-coherent, the functor

$$\mathcal{O}_X \otimes^{\mathbf{L}}_Y - = Lf^* : D^-(Y) \longrightarrow D^-(X)$$

induces, for $r \in \mathbb{Z} \cup \{-\infty\}$, a functor

$$Lf^* : D^-(g)_{r\text{-coh}} \longrightarrow D^-(h)_{r\text{-coh}}.$$

Corollary 1.14. In the situation of Proposition 1.11, if f is r-pseudo-coherent and g is s-pseudo-coherent, with $r, s \in \mathbb{Z} \cup \{-\infty\}$, then h is $\sup(r, s)$-pseudo-coherent. If h is r-pseudo-coherent and g is $(r+1)$-pseudo-coherent, then f is r-pseudo-coherent.

Remark 1.14.1. In particular, for $r = s = -1$, one recovers the assertions (ii) and (v) of EGA IV 1.4.3.

2. The finiteness theorem

Conjecture 2.1. Let S be a scheme, let $f : X \to Y$ be a proper S-morphism of schemes locally of finite type over S, and let $E \in \operatorname{ob} D^+(X)$. If E is pseudo-coherent relative to S, then the same is true of $\mathbf{R}f_*(E)$.

Theorem 2.2. The preceding conjecture is true in the following cases:

(i) S is locally noetherian; (ii) f is projective.

Proof in case (i). Since S is locally noetherian, the projection of X (respectively Y) onto S is a pseudo-coherent morphism, and the notions of pseudo-coherence over X (respectively Y) and relative to S coincide (Corollary 1.12). On the other hand, since X (respectively Y) is locally noetherian, hence $\mathcal{O}_X$ (respectively $\mathcal{O}_Y$) coherent, an object M of $D(X)$ (respectively $D(Y)$) is pseudo-coherent if and only if its $H^i(M)$ are coherent and M is locally in D^- (Exposé I, 3.5). The theorem therefore follows from:

Theorem 2.2.1. Let $f : X \to Y$ be a proper morphism of locally noetherian schemes, and let $E \in \operatorname{ob} D^+(X)$. If the $H^i(E)$ are coherent, then the same is true of $R^i f_*(E)$. If moreover E is locally in D^-, then the same is true of $\mathbf{R}f_*(E)$.

Proof. The first assertion follows from the spectral sequence

$$R^p f_*(H^q(E)) \Longrightarrow R^{p+q} f_*(E)$$

and from the finiteness theorem EGA III 3.2.1. For the second, one may suppose Y affine. Then X is quasi-compact and separated; suppose it covered by r affine opens. One knows (EGA III 1.4.12) that under these conditions, for a quasi-coherent $\mathcal{O}_X$-module M, one has $R^i f_*(M) = 0$ for every $i > r$. If E is locally in D^-, then $E \in D^-$, since X is quasi-compact; say $H^i(E) = 0$ for $i > N$. The preceding spectral sequence then gives $R^i f_*(E) = 0$ for $i > N + r$, which proves the assertion.

Proof in case (ii). The question being local on Y, one may suppose S and Y affine. There is then a Cartesian commutative diagram

$$\begin{array}{ccccc} X & \xrightarrow{i} & \mathbb{P}^r_Y & \xrightarrow{j} & \mathbb{P}^r_{Y'} \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle p} & & \downarrow{\scriptstyle p'} \\ Y & \longrightarrow & Y' & \xrightarrow[g]{} & S \end{array}$$

where i, j, j' are closed immersions, g' is smooth and affine, and p, p' are projections of projective spaces. Suppose that E is pseudo-coherent relative to S. By Theorem 1.1 (iii), this means that $(ji)_*(E)$ is pseudo-coherent. We must show that $\mathbf{R}f_*(E)$ is pseudo-coherent relative to S, that is, by Theorem 1.1 (iii), that

$$j'_*\mathbf{R}f_*(E)$$

is pseudo-coherent. But

$$j'_*\mathbf{R}f_*(E) \simeq \mathbf{R}p'_*((ji)_*(E)),$$

so the assertion is a consequence of the following more precise result.

Theorem 2.2.2. Let Y be an affine scheme, let

$$f : X = \mathbb{P}^r_Y \longrightarrow Y$$

be the projection of a projective space of finite type, and let $E \in \operatorname{ob} D^b(X)_{\mathrm{coh}}$. Then $\mathbf{R}f_*(E)$ is pseudo-coherent. Moreover, if E is acyclic in degree $> a$, then $\mathbf{R}f_*(E)$ is acyclic in degree $> a + r$, and there exists an integer N such that, for all $n \geq N$,

$$\mathbf{R}f_*(E(n)), \qquad E(n) = E \otimes \mathcal{O}_X(n),$$

is acyclic in degree $> a$.

Proof. Since Y is affine, X is quasi-compact and separated. By Exposé II, 2.2.9 a), E is isomorphic, in $D(X)$, to a complex F bounded above such that, for every i, $F^i \in \operatorname{ob} L(X)$, that is, F^i is a finite direct sum of sheaves of the type $\mathcal{O}_X(-n)$, $n \geq 0$. If E is acyclic in degree $> a$, F may be chosen so that $F^i = 0$ for $i > a$; this follows formally from the preceding assertion, taking account of Exposé I, 2.10 a), and Exposé II, 2.2.8 a). Replacing E by F, one may suppose that $E^i \in \operatorname{ob} L(X)$ for every i, and that $E^i = 0$ for $i > a$. Since X is covered by $r + 1$ affine opens, EGA III 1.4.10 and the hypercohomology spectral sequence give

$$R^i f_*(E) = 0 \qquad \text{for } i > a + r.$$

Let $t \leq a$ be an integer and put

$$E' = (0 \to E^t \to \cdots \to E^a \to 0).$$

There is an exact sequence

$$0 \longrightarrow E' \longrightarrow E \longrightarrow E'' \longrightarrow 0,$$

where E'' satisfies the same conditions as E, but with a replaced by $t - 1$. Applying $\mathbf{R}f_*$, one obtains a distinguished triangle

$$\mathbf{R}f_*(E') \longrightarrow \mathbf{R}f_*(E) \longrightarrow \mathbf{R}f_*(E'') \longrightarrow \mathbf{R}f_*(E')[1]$$

Since t can be chosen arbitrarily negative, it is enough, for the first assertion, to prove that $\mathbf{R}f_*(E')$ is $(t + r)$-pseudo-coherent. But $\mathbf{R}f_*(E'')$ is acyclic in degree $\geq t + r$, hence $(t + r)$-pseudo-coherent. Thus one wins by Exposé I, Proposition 2.6, if one proves that $\mathbf{R}f_*(E')$ is perfect.

For this one is reduced by dévissage to the case where E' is concentrated in degree 0 and equal to $\mathcal{O}_X(-n)$, $n > 0$. Then, by EGA III 2.1.16,

$$\mathbf{R}f_*(\mathcal{O}_X(-n)) \simeq R^r f_*(\mathcal{O}_X(-n))[-r].$$

Therefore $\mathbf{R}f_*(\mathcal{O}_X(-n))$ is perfect, and this ends the proof of the first assertion of Theorem 2.2.2. We have already seen that $\mathbf{R}f_*(E)$ is acyclic in degree $> a + r$. It remains to prove the last assertion. For $t < -r + a$, $\mathbf{R}f_*(E'')$ is acyclic in degree $> a$. Taking account of the preceding triangle, one is reduced to doing the proof for E' instead of for E. Since E' is bounded above and has components in $L(X)$, there is an integer N such that, for all $n \geq N$, the components of $E'(n)$ are finite direct sums of sheaves of type $\mathcal{O}_X(p)$ with $p \geq 0$. Then, by EGA III 2.1.16 and the hypercohomology spectral sequence, $\mathbf{R}f_*(E'(n))$ is acyclic in degree $> a$ for all $n \geq N$, which completes the proof of Theorem 2.2.2 and hence of Theorem 2.2.

We also have the following classical complement to 2.2 (ii), which will be given for later reference.

Corollary 2.3 (EGA III 2.2.1). Let S be a quasi-compact scheme, $f : X \to Y$ a projective S-morphism of finite type schemes over S, and let

$$L = i^*\mathcal{O}_P(1)$$

be the invertible sheaf defined by an extension $i : X \to P = P(F)$, where F is a quasi-coherent $\mathcal{O}_Y$-module of finite type. For $M \in \operatorname{ob} D(X)$ and $n \in \mathbb{Z}$, put

$$M(n) = M \otimes L^{\otimes n}.$$

If $E \in \operatorname{ob} D^+(X)$ is pseudo-coherent relative to S and acyclic in degree $> a$, then there exists an integer N such that, for all $n \geq N$, $\mathbf{R}f_*(E(n))$ has the same properties.

Proof. One reduces trivially, as in the proof of Theorem 2.2 (ii), to the situation of Theorem 2.2.2: $Y = S$, $f : X = \mathbb{P}^r_Y \to Y$ the canonical projection, $L = \mathcal{O}_X(1)$ the canonical sheaf, $E \in \operatorname{ob} D^b(X)$ a pseudo-coherent complex acyclic in degree $> a$. The conclusion then follows from Theorem 2.2.2.

Corollary 2.4. Let S be a quasi-compact scheme and let $f : X \to Y$ be a proper S-morphism of schemes of finite type over S. If S is noetherian, or if f is projective, the functor

$$\mathbf{R}f_* : D^+(X) \longrightarrow D^+(Y)$$

induces a functor

$$\mathbf{R}f_* : D^b(X)_{S\text{-coh}} \longrightarrow D^b(Y)_{S\text{-coh}}.$$

Proof. Consequence of Theorem 2.2 and of the fact that there is then an integer N such that, for every quasi-coherent $\mathcal{O}_X$-module E, $R^i f_*(E) = 0$ for all $i > N$.

Corollary 2.5. Let $f : X \to Y$ be a proper and pseudo-coherent morphism, and let $E \in \operatorname{ob} D^+(X)$. Suppose Y locally noetherian or f projective. If E is pseudo-coherent in the absolute sense, then the same is true of $\mathbf{R}f_*(E)$. If Y is quasi-compact, the functor $\mathbf{R}f_*$ induces a functor

$$\mathbf{R}f_* : D^b(X)_{\text{coh}} \longrightarrow D^b(Y)_{\text{coh}}.$$

Proof. Consequence of Theorem 2.2, Corollary 2.4, and Corollary 1.12.

Scholie 2.6. To prove Conjecture 2.1 in general, new techniques will surely have to be introduced. One may hope that they will one day make it possible to prove the analogous conjecture in analytic geometry, for a proper morphism of analytic spaces over a suitably topologized locally ringed topos in $\mathbb{C}$-algebras. For the present this conjecture has been proved only over a complex analytic space, by Grauert's theorem.[21]

[21] Added in April 1971: see a forthcoming article of R. Kiehl and J.-L. Verdier, where the finiteness theorem is proved by different, simpler techniques and under more general hypotheses.

3. Relative finite Tor-dimension

Definition 3.1. Let

$$f : (X, \mathcal{O}_X) \longrightarrow (Y, \mathcal{O}_Y)$$

be a morphism of ringed topoi, let $E \in \mathrm{ob}\, D^-(X)$, and let $[m, n]$ be an interval of $\mathbb{Z}$. We say that E is of flat amplitude relative to f (or to Y, if there is no possible confusion) contained in $[m, n]$, and write

$$\mathrm{tor.amp}_f(E) \subset [m, n] \qquad (\text{or } \mathrm{tor.amp}_Y(E) \subset [m, n]),$$

if E, considered as a complex of $f^{-1}(\mathcal{O}_Y)$-modules, is of flat amplitude contained in $[m, n]$ in the sense of Exposé I, 5.2. We say that f is of flat amplitude contained in $[-a, 0]$, or of Tor-dimension $\leq a$, if $\mathcal{O}_X$ is of flat amplitude relative to f contained in $[-a, 0]$. We say that E is of finite flat amplitude relative to f if there exists an interval $[m, n]$ such that $\mathrm{tor.amp}_f(E) \subset [m, n]$.

Notation 3.2. We write

$$D(f)_{\mathrm{torf}}, \qquad D(X)_{f\text{-}\mathrm{torf}}, \qquad D(X)_{Y\text{-}\mathrm{torf}}$$

if no confusion is possible, for the full subcategory of $D^-(X)$ formed by complexes of finite flat amplitude relative to f. By Exposé I, 5.3, this is a triangulated subcategory of $D^b(X)$.

Proposition 3.3. With the notation of Definition 3.1, suppose that X has enough points (SGA 4 XVII IV 6.4). The following conditions are then equivalent:

(i) $\mathrm{tor.amp}_f(E) \subset [m, n]$.

(ii) For every point x of X, one has

$$\mathrm{tor.amp}_y(E_x) \subset [m, n],$$

where $y = f(x)$, ringed by $\mathcal{O}_{Y,y}$.

(iii) For every object V of Y and every $\mathcal{O}_V$-module M, one has

$$H^i\left(E|_{f^{-1}(V)} \otimes^{\mathbf{L}}_{\mathcal{O}_V} M\right) = 0 \quad \text{for } i \notin [m, n].$$

Equivalently, for every $\mathcal{O}_V$-module M,

$$E|_{f^{-1}(V)} \otimes^{\mathbf{L}}_{\mathcal{O}_V} M \simeq E|_{f^{-1}(V)} \otimes^{\mathbf{L}}_{\mathcal{O}_V} L!f^*(M).$$

(iv) The same condition as (iii), but with M the cokernel of a homomorphism

$$\mathcal{O}_V^q \longrightarrow \mathcal{O}_V^p, \qquad p, q \in \mathbb{N}.$$

Proof. The equivalence (i)$\Longleftrightarrow$(ii) follows from Exposé I, 5.6.2, and the implications (ii)$\Rightarrow$(iii)$\Rightarrow$(iv) are trivial. We prove (iv)$\Rightarrow$(ii). Let x be a point of X, $y = f(x)$. One has to show that

$$H^i(E_x \otimes^{\mathbf{L}}_{\mathcal{O}_{Y,y}} M) = 0$$

for every $\mathcal{O}_{Y,y}$-module M and every $i \notin [m, n]$. Since every $\mathcal{O}_{Y,y}$-module is an inductive filtered limit of modules of finite presentation, one may restrict to M of finite presentation. If M is a finitely presented $\mathcal{O}_{Y,y}$-module, the same argument as for ordinary ringed spaces (EGA I, 5.3.9) shows that there exists a y-pointed object V of Y and an $\mathcal{O}_V$-module P, cokernel of a homomorphism

$$\mathcal{O}_V^q \longrightarrow \mathcal{O}_V^p, \qquad p, q \in \mathbb{N},$$

such that $P_y \simeq M$. One then has

$$\left(E|_{f^{-1}(V)} \otimes^{\mathbf{L}}_{\mathcal{O}_V} P\right)_x \simeq E_x \otimes^{\mathbf{L}}_{\mathcal{O}_{Y,y}} M,$$

by the commutation of tensor product with passage to fibers, and hypothesis (iv) implies the desired vanishing.

Remark 3.3.1. The editor does not know whether the equivalences (i)$\Longleftrightarrow$(iii)$\Longleftrightarrow$(iv) are true without the hypothesis that X has enough points.

Corollary 3.4. Let

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & \searrow^{h} & \downarrow{\scriptstyle g} \\ & & Z \end{array}$$

be a commutative triangle of ringed topoi, where X is assumed to have enough points. Let $E \in \operatorname{ob} D(X)$, $F \in \operatorname{ob} D(Y)$, and let $[a,b]$, $[c,d]$ be intervals of $\mathbb{Z}$. Then

$$\operatorname{tor.amp}_f(E) \subset [a,b] \quad \text{and} \quad \operatorname{tor.amp}_g(F) \subset [c,d]$$

imply

$$\operatorname{tor.amp}_h(E \otimes^{\mathbf{L}}_Y F) \subset [a+c, b+d].$$

Proof. By Proposition 3.3, one must show that the relation on the left implies

$$H^i\left(((E \otimes^{\mathbf{L}}_Y F)|_{h^{-1}(Z')}) \otimes^{\mathbf{L}}_{\mathcal{O}_{Z'}} M\right) = 0$$

for every $i \notin [a+c, b+d]$ and every $\mathcal{O}_{Z'}$-module M, where Z' is an object of Z. Put $Y' = g^{-1}(Z')$, $X' = f^{-1}(Y') = h^{-1}(Z')$. Then

$$((E \otimes^{\mathbf{L}}_Y F)|_{X'}) \otimes^{\mathbf{L}}_{Z'} M \simeq (E|_{X'}) \otimes^{\mathbf{L}}_{Y'} ((F|_{Y'}) \otimes^{\mathbf{L}}_{Z'} M),$$

and the assertion follows at once from the hypotheses.

In particular:

Corollary 3.4.1. Under the hypotheses of Corollary 3.4:

a) If g is of Tor-dimension $\leq n$, then

$$\operatorname{tor.amp}_f(E) \subset [a,b] \Longrightarrow \operatorname{tor.amp}_h(E) \subset [a-n, b].$$

b) If f is of Tor-dimension $\leq m$, then

$$\operatorname{tor.amp}_g(F) \subset [c,d] \Longrightarrow \operatorname{tor.amp}_h(Lf^*(F)) \subset [c-m, d].$$

Remark 3.4.2. Let $f : X \to Y$ be a morphism of finite Tor-dimension and $E \in \operatorname{ob} D(X)$. By Corollary 3.4.1 a), if E is of finite flat amplitude in the absolute sense, then E is of finite flat amplitude relative to f. But the converse is false, even if f is flat, as is shown by the example of a singularity of a scheme over a field.

Proposition 3.5. Let S be a scheme, and for $i = 1, 2$ let

$$f_i : X_i \longrightarrow Y_i$$

be an S-morphism, with $E_i \in \operatorname{ob} D^-(X_i)$, and let $[a_i, b_i]$ be an interval of $\mathbb{Z}$. Suppose that X_1 and X_2, and also Y_1 and Y_2, are Tor-independent over S. Put

$$a = a_1 + a_2, \qquad b = b_1 + b_2, \qquad f = f_1 \times_S f_2 : X \to Y.$$

Then:

a) If $\mathrm{tor.amp}_{f_1}(E_1) \subset [a_1, b_1]$, and if E_2 is acyclic outside $[a_2, b_2]$, then

$$E_1 \otimes_S^{\mathbf{L}} E_2$$

is acyclic outside $[a, b]$.

b) If $\mathrm{tor.amp}_{f_i}(E_i) \subset [a_i, b_i]$ for $i = 1, 2$, then

$$\mathrm{tor.amp}_f(E_1 \otimes_S^{\mathbf{L}} E_2) \subset [a, b].$$

Proof. By Proposition 3.3, it is enough to verify the assertion on the fibers. Let s be a point of S, x a point of X above s, $y = f(x)$, and let x_i (respectively y_i) be the canonical projection of x (respectively y) onto X_i (respectively Y_i). Put

$$(E_i)_{x_i} = M_i, \quad \mathcal{O}_{X_i,x_i} = A_i, \quad \mathcal{O}_{Y_i,y_i} = B_i, \quad \mathcal{O}_{S,s} = C,$$

and

$$\mathcal{O}_{X,x} = A = A_1 \otimes_C A_2, \qquad \mathcal{O}_{Y,y} = B = B_1 \otimes_C B_2.$$

Then

$$(E_1 \otimes_S^{\mathbf{L}} E_2)_x \simeq M_1 \otimes_{A_1}^{\mathbf{L}} A \otimes_{A_2}^{\mathbf{L}} M_2.$$

The Tor-independence hypotheses imply on the other hand that

$$A \simeq A_1 \otimes_{B_1}^{\mathbf{L}} B \otimes_{B_2}^{\mathbf{L}} A_2.$$

Consequently, the second member of the displayed isomorphism is canonically isomorphic, in the derived category $D(B)$ of B-modules, to

$$M_1 \otimes_{B_1}^{\mathbf{L}} B \otimes_{B_2}^{\mathbf{L}} M_2.$$

The relations $\mathrm{tor.amp}_{f_i}(E_i) \subset [a_i, b_i]$, $i = 1, 2$, imply

$$\mathrm{tor.amp}_{B_i}(M_i) \subset [a_i, b_i],$$

hence, by Exposé I, 5.5,

$$\mathrm{tor.amp}_B(M_1 \otimes_{B_1}^{\mathbf{L}} B \otimes_{B_2}^{\mathbf{L}} M_2) \subset [a, b],$$

which proves b). If, on the other hand, $\mathrm{tor.amp}_{f_1}(E_1) \subset [a_1, b_1]$, M_1 is isomorphic to a complex of flat B_1-modules, zero outside $[a_1, b_1]$, and if E_2, hence M_2, is acyclic outside $[a_2, b_2]$, then

$$M_1 \otimes_{B_1}^{\mathbf{L}} B \otimes_{B_2}^{\mathbf{L}} M_2$$

is acyclic outside $[a, b]$. This proves a) and completes the proof.

Corollary 3.5.1. Under the hypotheses of Proposition 3.5, if f_1 and f_2 are of finite Tor-dimension, then so is f.

Corollary 3.5.2. Let

$$\begin{array}{ccc} X' & \xrightarrow{g} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow[h]{} & Y \end{array}$$

be a Cartesian square of schemes, where X and Y' are assumed Tor-independent over Y, and let $E \in \mathrm{ob}\, D(X)$. Then one has

$$\mathrm{tor.amp}_f(E) \subset [a, b] \Longrightarrow \mathrm{tor.amp}_{f'}(Lg^*(E)) \subset [a, b],$$

and consequently the functor $Lg^* : D^-(X) \to D^-(X')$ induces a functor

$$Lg^* : D(f)_{\mathrm{torf}} \longrightarrow D(f')_{\mathrm{torf}}.$$

Proposition 3.6. Let

$$\begin{array}{ccc} X & \xrightarrow{\ i\ } & X' \\ {\scriptstyle f}\downarrow & \swarrow_{f'} & \\ Y & & \end{array}$$

be a commutative triangle of schemes, where i is a closed immersion and f' is smooth, and let $E \in \mathrm{ob}\, D(X)$. For E to be locally of finite flat amplitude relative to f, it is necessary and sufficient that $i_*(E)$ be locally of finite flat amplitude in the absolute sense. More precisely, if f' is of relative dimension $\leq d$, then

$$\text{(i)} \quad \mathrm{tor.amp}(i_*E) \subset [a,b] \Longrightarrow \mathrm{tor.amp}_f(E) \subset [a,b],$$
$$\text{(ii)} \quad \mathrm{tor.amp}_f(E) \subset [a,b] \Longrightarrow \mathrm{tor.amp}(i_*E) \subset [a-d,b].$$

Proof. If $[m,n]$ is an interval in $\mathbb{Z}$, one has evidently

$$\mathrm{tor.amp}(E) \subset [m,n] \Longleftrightarrow \mathrm{tor.amp}(i_*E) \subset [m,n]$$

in the reduction in which one tests by modules after the closed immersion. Thus it remains to treat the case $X = X'$, $i = \mathrm{Id}_X$, $f = f'$. Assertion (i) is immediate from (3.4.1 a). For (ii), consider the diagonal section

$$s : X \longrightarrow X \times_Y X$$

of the two projections. If f is smooth of relative dimension d, then, by VII 1.10, s is a regular immersion of codimension $\leq d$, hence of Tor-dimension $\leq d$ (as is seen from the Koszul complex). By (3.5.2),

$$\mathrm{tor.amp}_f(E) \subset [a,b] \Longleftrightarrow \mathrm{tor.amp}_{\mathrm{pr}_2}(\mathrm{pr}_1^* E) \subset [a,b].$$

By (3.4.1 b) it follows that

$$\mathrm{tor.amp}(s^* \mathrm{pr}_1^* E) \subset [a-d,b],$$

and the implication follows because $s^* \mathrm{pr}_1^* \simeq \mathrm{Id}$.

Remark 3.6.1. The statement (3.6) would be false if one supposed only that f' were flat; see (3.4.2).

Proposition 3.7 (projection formula). Let S be a quasi-compact scheme, let $f : X \to Y$ be a quasi-compact and quasi-separated S-morphism of quasi-compact schemes over S, let $E \in \mathrm{ob}\, D^-(X)_{\mathrm{qcoh}}$, and let $M \in \mathrm{ob}\, D^b(S)_{\mathrm{qcoh}}$. If M has finite flat amplitude, or if E has finite flat amplitude relative to S, there is a functorial canonical isomorphism in $D(Y)_{\mathrm{qcoh}}$

$$Rf_*(E) \otimes_S^{\mathbf{L}} M \xrightarrow{\sim} Rf_*(E \otimes_S^{\mathbf{L}} M).$$

Proof. First, by EGA III 1.4.12 and IV 1.7.21, there is an integer N such that $R^i f_*(F) = 0$ for $i > N$ and for every quasi-coherent $\mathcal{O}_X$-module F. Hence Rf_* sends $D^-(X)_{\mathrm{qcoh}}$ into $D^-(Y)_{\mathrm{qcoh}}$. The adjunction arrow

$$Lf^* Rf_*(E) \longrightarrow E$$

yields, after tensoring with M, an arrow

$$Lf^*(Rf_*(E) \otimes_S^{\mathbf{L}} M) \longrightarrow E \otimes_S^{\mathbf{L}} M,$$

and therefore, by adjunction, the canonical arrow

$$Rf_*(E) \otimes_S^{\mathbf{L}} M \longrightarrow Rf_*(E \otimes_S^{\mathbf{L}} M). \qquad (*)$$

Both sides have quasi-coherent cohomology. The assertion is local on Y, so assume S and Y affine. If M has finite flat amplitude, devissage and the way-out property of the two functors in $(*)$ reduce successively to M an ordinary quasi-coherent module, then to M free, then to M free of finite type, and finally to $M = \mathcal{O}_S$, where $(*)$ is tautological. If instead E has finite flat amplitude relative to S, devissage reduces to the case $M = P$, with P a flat A-module and $S = \operatorname{Spec} A$. Put $A' = D_A(P)$ (EGA 0_{IV}, 18.2.3) and $S' = \operatorname{Spec} A'$. Then the assertion is the flat base-change assertion that

$$q^* Rf_*(E) \longrightarrow Rf'_* p^*(E)$$

is an isomorphism for the base change to S', which is EGA III 1.4.15 together with IV 1.7.21.

Corollary 3.7.1. Let S be a scheme, let $f : X \to Y$ be a quasi-compact and quasi-separated S-morphism of quasi-compact schemes over S, and let $E \in \operatorname{ob} D^-(X)_{\mathrm{qcoh}}$. If E is locally of finite flat amplitude relative to S, then the same is true of $Rf_*(E)$. More precisely, if S is quasi-compact and if N is an integer such that $R^i f_*(F) = 0$ for $i > N$ and every quasi-coherent $\mathcal{O}_X$-module F, then

$$\text{tor. amp}_S(E) \subset [a, b] \Longrightarrow \text{tor. amp}_S(Rf_* E) \subset [a, b + N].$$

Proof. By (3.3 (1) (iv)), and using that Rf_* commutes with restriction to an open of S, it suffices to prove that the hypothesis implies

$$H^i(Rf_* E \otimes_S^{\mathbf{L}} M) = 0$$

for $i \notin [a, b + N]$ and every quasi-coherent $\mathcal{O}_S$-module M. But the hypothesis says that $H^i(E \otimes_S^{\mathbf{L}} M) = 0$ for $i \notin [a, b]$, and (3.7) gives the result.

Corollary 3.7.2. Let $f : X \to Y$ be quasi-compact, quasi-separated, and locally of finite Tor-dimension, and let $E \in \operatorname{ob} D^-(X)_{\mathrm{qcoh}}$. If E is locally of finite flat amplitude in the absolute sense, then so is $Rf_*(E)$.

Proof. Combine (3.4.1 a) and (3.7.1).

4. Relative perfection

Definition 4.1. Let $f : X \to Y$ be a morphism locally of finite type of schemes, let $E \in \operatorname{ob} D(X)$, and let $[a, b]$ be an interval of $\mathbb{Z}$. We say that E is of perfect amplitude relative to f (or to Y, if there is no ambiguity), contained in $[a, b]$, and write

$$\text{parf. amp}_f(E) \subset [a, b]$$

if E, relative to f, is pseudo-coherent (1.2) and of flat amplitude contained in $[a, b]$ (3.1). We say that f is of perfect amplitude contained in $[-n, 0]$, or of perfect dimension $\leq n$, if $\mathcal{O}_X$ has perfect amplitude contained in $[-n, 0]$. We say that E is of finite perfect amplitude relative to f if such an interval $[a, b]$ exists. We say that E is perfect relative to f if it is locally of finite perfect amplitude relative to f. We say that f is perfect if $\mathcal{O}_X$ is locally of finite perfect amplitude relative to f.

Example 4.1.1. A regular immersion of codimension d (VII 1.4) is of perfect dimension $\leq d$, as follows from the Koszul complex. A morphism locally a complete intersection, i.e. locally the composite of a regular immersion and a smooth morphism, is a perfect morphism.

Notation 4.2. Let $f : X \to Y$ be locally of finite type. We write

$$D(f)_{\mathrm{parf}}, \qquad D(f)_{\mathrm{parf}}, \qquad D(f)^{-}_{\mathrm{parf}}$$

when no confusion is possible, for the full subcategories of $D(X)$ formed by complexes perfect, respectively of finite perfect amplitude, relative to f. By (I 5.3) and (1.4), these are triangulated subcategories of $D(X)$. If X is quasi-compact, the two finite-amplitude/perfect notations coincide in the evident bounded sense.

Proposition 4.3 (cf. I 5.8). Let $f : X \to Y$ be locally of finite type, let $E \in \mathrm{ob}\, D(X)$, let $[a, b]$ be an interval of $\mathbb{Z}$, and let $x \in X$, $y = f(x)$. The following conditions are equivalent:

i) $\mathrm{parf.\,amp}_f(E) \subset [a, b]$ in a neighbourhood of x;

ii) in a neighbourhood of x, E is $(a-1)$-pseudo-coherent relative to f, is acyclic outside $[a, b]$, and
$$\mathrm{tor.\,amp}_{\mathcal{O}_{Y,y}}(E_x) \subset [a, b].$$

Proof. The implication i) $\Rightarrow$ ii) is immediate. For the converse, the question is local around x, and by the definitions one reduces to the case where f is smooth. Then E is $(a-1)$-pseudo-coherent near x; after localizing, one may assume that E is strictly $(a-1)$-pseudo-coherent and zero in degrees $> b$. After truncating, one may represent it by a complex with E^i free of finite type for $i > a$, E^a of finite presentation, and zero outside $[a, b]$. By (I 5.1.1), the term in degree a modulo boundaries is flat relative to f near x. Since f is smooth, one embeds locally into an affine space over Y and descends finite presentation and flatness from a noetherian approximation; pseudo-coherence follows from (1.10 a), and the desired perfect-amplitude assertion follows.

Corollary 4.3.1. Let $f : X \to Y$ be locally of finite type and let E be an $\mathcal{O}_X$-module. One has $\mathrm{parf.\,amp}_f(E) \subset [0, 0]$ if and only if E is flat and of finite presentation relative to f (1.2.1 c). In particular, f is of perfect dimension zero if and only if f is flat and locally of finite presentation.

Corollary 4.3.2. Let $f : X \to Y$ be locally of finite type, let E be a complex of $\mathcal{O}_X$-modules flat and of finite presentation relative to f, and let $[a, b]$ be an interval. If $E^i = 0$ for $i \notin [a, b]$, then $\mathrm{parf.\,amp}_f(E) \subset [a, b]$. If E is bounded above, then E is pseudo-coherent relative to f.

Proof. This follows from (4.3.1) and from I 4.15 and I 4.8.

Proposition 4.4. Let

$$\begin{array}{ccc} X & \xrightarrow{\ i\ } & X' \\ {\scriptstyle f}\downarrow & \swarrow{\scriptstyle g} & \\ Y & & \end{array}$$

be a commutative triangle of schemes, where i is a closed immersion and g is smooth, and let $E \in \mathrm{ob}\, D(X)$. Then E is perfect relative to f if and only if $i_*(E)$ is perfect in the absolute sense. More precisely, if g has relative dimension $\leq d$, then

$$\mathrm{parf.\,amp}(i_*E) \subset [a, b] \Longrightarrow \mathrm{parf.\,amp}_f(E) \subset [a, b],$$
$$\mathrm{parf.\,amp}_f(E) \subset [a, b] \Longrightarrow \mathrm{parf.\,amp}(i_*E) \subset [a - d, b].$$

Proof. This is an immediate consequence of (3.6).

Proposition 4.5. Let

$$\begin{array}{ccc} X & \xrightarrow{\ f\ } & Y \\ & {\scriptstyle h}\searrow & \downarrow{\scriptstyle g} \\ & & S \end{array}$$

be a commutative triangle of morphisms locally of finite type, let $E \in \operatorname{ob} D(X)$, $F \in \operatorname{ob} D(Y)$, and let $[a,b]$, $[c,d]$ be intervals of $\mathbb{Z}$. Then

$$\operatorname{parf.amp}_f(E) \subset [a,b], \quad \operatorname{parf.amp}_g(F) \subset [c,d] \Longrightarrow \operatorname{parf.amp}_h(E \otimes_Y^{\mathbf{L}} F) \subset [a+c, b+d].$$

In particular, if E is perfect relative to f and F is perfect relative to g, then $E \otimes_Y^{\mathbf{L}} F$ is perfect relative to h.

Proof. Combine (1.1) and (3.4).

Corollary 4.5.1. Under the hypotheses of (4.5):

a) if g is of perfect dimension $\leq n$, then

$$\operatorname{parf.amp}_f(E) \subset [a,b] \Longrightarrow \operatorname{parf.amp}_h(E) \subset [a-n, b];$$

therefore, if g is perfect, E perfect relative to f implies E perfect relative to h;

b) if f is of perfect dimension $\leq m$, then

$$\operatorname{parf.amp}_g(F) \subset [c,d] \Longrightarrow \operatorname{parf.amp}_h(Lf^*F) \subset [c-m, d];$$

therefore, if f is perfect, F perfect relative to g implies Lf^*F perfect relative to h.

Remark 4.5.2. With the preceding notation, if g is perfect, E perfect relative to h does not necessarily imply that E is perfect relative to f; the usual example of a singular point of a scheme over a field already shows this. The following criterion is available.

Proposition 4.6 (criterion of perfection by fibers). Let

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ & \searrow^{h} & \downarrow{\scriptstyle g} \\ & & S \end{array}$$

be a commutative triangle of morphisms of schemes. Suppose that f and h are locally of finite type, and that g is locally of finite presentation and flat. Let $x \in X$, $y = f(x)$, $s = h(x) = g(y)$, and let $E \in \operatorname{ob} D(X)$. Let $[a,b]$ be an interval of $\mathbb{Z}$, and let $f_s : X_s \to Y_s$ be the fiber of f over s, i.e. the morphism obtained from f by the base change $\operatorname{Spec} k(s) \to S$. Then the following conditions are equivalent:

i) $\operatorname{parf.amp}_h(E) \subset [a,b]$ near x, and

$$\operatorname{tor.amp}_{\mathcal{O}_{Y_s,y}}(E_x \otimes^{\mathbf{L}}_{\mathcal{O}_{Y,y}} \mathcal{O}_{Y_s,y}) \subset [a,b];$$

ii) $\operatorname{parf.amp}_f(E) \subset [a,b]$ near x.

Proof. The implication ii) $\Rightarrow$ i) follows because g has perfect dimension zero by (4.3.1), hence (4.5.1 a) gives $\operatorname{parf.amp}_h(E) \subset [a,b]$ near x; the asserted Tor-amplitude condition follows from (4.3). Conversely, the question is local around x. We may factor f as a closed immersion followed by a smooth morphism. Replacing E by its direct image under the immersion and replacing the smooth factor accordingly does not change the conditions; hence one may suppose f smooth. Since g is perfect of dimension zero and h is perfect by hypothesis, E is pseudo-coherent. After localizing, use (II 2.2.10 b) and (I 2.10 a) to suppose that E is strictly pseudo-coherent, zero in degrees $> b$, and quasi-isomorphic to the truncation

$$t : E \longrightarrow (0 \to E^a/B^a \to E^{a+1} \to \cdots \to E^b \to 0).$$

It remains to prove that E^a/B^a is f-flat near x. Let $i : X_s \to X$ be the canonical map. One has

$$E_x \otimes^{\mathbf{L}}_{mathcalO_{Y,y}} \mathcal{O}_{Y_s,y} \simeq i^*(E)_x.$$

Using (3.5.2), the Tor-amplitude hypothesis on the fiber shows that the truncated complex $i^*(t)$ is a quasi-isomorphism, so $i^*(E^a/B^a)_x$ is flat over $\mathcal{O}_{Y_s,y}$. On the other hand, the Tor-amplitude of E relative to h implies that E^a/B^a is h-flat. The usual criterion of flatness by fibers (EGA IV 11.3.10) then gives that E^a/B^a is f-flat near x.

Corollary 4.6.1. Let $f : X \to S$ be locally of finite presentation and flat, let $x \in X$, $s = f(x)$, let $E \in \operatorname{ob} D(X)$, and let $[a, b]$ be an interval. If $i_s : X_s = X \times_S \operatorname{Spec} k(s) \to X$ is the canonical projection and $E_s = Li_s^*E$, then

$$\operatorname{parf.amp}_S(E) \subset [a, b] \text{ near } x, \quad \operatorname{tor.amp}(E_s) \subset [a, b]$$

if and only if

$$\operatorname{parf.amp}(E) \subset [a, b] \text{ near } x.$$

Consequently E is perfect if and only if E is perfect relative to f and E_s is perfect for every $s \in S$.

Proof. Apply (4.6) with $X = Y$ and $f = \mathrm{Id}_X$.

Remark 4.6.2. From (4.6.1) and I 5.10 it follows that, if f is locally of finite presentation, flat, and has regular schemes as fibers, then E perfect relative to f is equivalent to E perfect. This equivalence was already obtained in (4.4) when f is smooth.

Proposition 4.7. Let S be a scheme, and for $i = 1, 2$ let

$$f_i : X_i \longrightarrow Y_i$$

be an S-morphism locally of finite type, with $E_i \in \operatorname{ob} D(X_i)$ and intervals $[a_i, b_i]$. Suppose that X_1 and X_2, and also Y_1 and Y_2, are Tor-independent over S. Put $a = a_1 + a_2$, $b = b_1 + b_2$, and $f = f_1 \times_S f_2$. Then:

a) if $\operatorname{parf.amp}_{f_1}(E_1) \subset [a_1, b_1]$, and if E_2 is pseudo-coherent relative to f_2 and acyclic outside $[a_2, b_2]$, then $E_1 \otimes^{\mathbf{L}}_S E_2$ is pseudo-coherent relative to f and acyclic outside $[a, b]$;

b) if $\operatorname{parf.amp}_{f_i}(E_i) \subset [a_i, b_i]$ for $i = 1, 2$, then

$$\operatorname{parf.amp}_f(E_1 \otimes^{\mathbf{L}}_S E_2) \subset [a, b].$$

Proof. Combine (1.9) and (3.5).

Corollary 4.7.1. Under the hypotheses of (4.7), if f_i has perfect dimension $\leq n_i$ for $i = 1, 2$, then f has perfect dimension $\leq n_1 + n_2$. Consequently, if f_1 and f_2 are perfect, then so is f.

Corollary 4.7.2. In a Cartesian square

$$\begin{array}{ccc} X' & \xrightarrow{g} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow[h]{} & Y, \end{array}$$

where f is locally of finite type and X and Y' are Tor-independent over Y, one has

$$\operatorname{parf.amp}_f(E) \subset [a, b] \Longrightarrow \operatorname{parf.amp}_{f'}(Lg^*E) \subset [a, b].$$

Consequently $Lg^* : D^-(X) \to D^-(X')$ sends $D(f)_{\mathrm{parf}}$, respectively $D(f)_{\mathrm{parf}}$, into the corresponding categories for f'.

Proposition 4.8. Let S be a scheme, let $f : X \to Y$ be a proper S-morphism of S-schemes locally of finite type, and let $E \in \mathrm{ob}\, D^-(X)$. Under the proviso that (2.1) is valid for f (hence at least if S is locally noetherian or if f is projective):

a) if E is perfect relative to S, then so is $Rf_*(E)$;

b) if S is quasi-compact, X and Y are of finite type over S, $[a, b]$ is an interval, and N is such that $R^i f_*(M) = 0$ for $i > N$ and every quasi-coherent $\mathcal{O}_X$-module M, then

$$\mathrm{parf.\,amp}_S(E) \subset [a, b] \Longrightarrow \mathrm{parf.\,amp}_S(Rf_*E) \subset [a, b + N].$$

Consequently Rf_* sends perfect complexes relative to S to perfect complexes relative to S.

Proof. Assertion a) follows from b), and b) is obtained by combining (2.1) and (3.7).

Corollary 4.8.1. Let $f : X \to Y$ be proper and perfect, and let $E \in \mathrm{ob}\, D^-(X)$. Under the proviso that (2.1) holds for f, if E is perfect then $Rf_*(E)$ is perfect. If moreover Y is quasi-compact, Rf_* sends $D(X)_{\mathrm{parf}}$ to $D(Y)_{\mathrm{parf}}$.

Proof. If E is perfect, then E is perfect relative to f by (4.5.1 a).

Proposition 4.9. Let S be noetherian, let X and Y be S-schemes of finite type, let $f : X \to Y$ be a compactifiable S-morphism, i.e. the composite of an open immersion and a proper morphism, and let $E \in \mathrm{ob}\, D(X)$, $F \in \mathrm{ob}\, D^-(Y)$. If E is perfect relative to f and F is perfect relative to S, then

$$\mathrm{RHom}(E, f^!F)$$

is perfect relative to S.

Proof. The question is local on X. One may suppose that f factors as

$$X \xrightarrow{i} X' \xrightarrow{f'} Y,$$

where i is a closed immersion and f' is smooth. If E is perfect relative to f, then it is perfect relative to i by (4.4); if F is perfect relative to S, then $f'^!F$ is perfect relative to S by (4.5.1 b), since $f'^!F$ is locally isomorphic to f'^*F up to translation. As $f^! = i^! f'^!$, it remains to prove the assertion when f is a closed immersion. Then f_*E is perfect and, by global duality ([H] III 6.7),

$$f_*\mathrm{RHom}(E, f^!F) \simeq \mathrm{RHom}(f_*E, F).$$

Since f_*E is perfect, (I 7.7) gives

$$\mathrm{RHom}(f_*E, F) \simeq (f_*E)^\vee \otimes^{\mathbf{L}} F,$$

and the result follows from (4.5) with the identity morphism on Y.

Corollary 4.9.1. Under the hypotheses of (4.8), if f is perfect, then $f^!$ sends $D(Y)_{\mathrm{parf}}$ into $D(X)_{\mathrm{parf}}$.

Proof. Take $E = \mathcal{O}_X$ in (4.9).

Corollary 4.9.2. Let S be noetherian and let $f : X \to S$ be compactifiable. Put $K_X = f^!(\mathcal{O}_S)$, and $D_X(\cdot) = \mathrm{RHom}(\cdot, K_X)$. For $E \in \mathrm{ob}\, D(f)_{\mathrm{parf}}$, one has $D_X(E) \in \mathrm{ob}\, D(f)_{\mathrm{parf}}$, and the canonical arrow

$$E \longrightarrow D_X D_X(E)$$

is an isomorphism.

Proof. For the first assertion, apply (4.9) with $Y = S$ and $F = \mathcal{O}_S$. For the second, one reduces easily to the case where f is a closed immersion. It is enough then to apply f_* to the canonical arrow. By global duality one has $f_* D_X = D_S f_*$, and one is reduced to ordinary biduality for perfect complexes (I 7.2).

5. Applications: exchange and semi-continuity theorems

Lemma 5.1. Let $(X, \mathcal{O}_X)$ be a commutatively ringed topos, let $\mathrm{Mod}(X)$ be the category of $\mathcal{O}_X$-modules, and write $D(X) = D(\mathrm{Mod}(X))$. Let $E \in \mathrm{ob}\, D(X)$ and let $p \in \mathbb{Z}$. Consider the following conditions:

a) the functor $M \mapsto H^p(E \otimes^{\mathbf{L}} M)$ from $\mathrm{Mod}(X)$ to $\mathrm{Mod}(X)$ is right exact;

a′ the canonical map
$$H^p(E) \otimes M \longrightarrow H^p(E \otimes^{\mathbf{L}} M)$$
is an isomorphism for all $M \in \mathrm{ob}\, \mathrm{Mod}(X)$;

b the functor $M \mapsto H^{p+1}(E \otimes^{\mathbf{L}} M)$ is left exact;

b′ the canonical map defined below
$$H^{p+1}(E \otimes^{\mathbf{L}} M) \longrightarrow \mathrm{Hom}(H^{-p-1}(E^\vee), M)$$
is an isomorphism for all $M \in \mathrm{ob}\, \mathrm{Mod}(X)$.

Then
$$\mathrm{a} \Longleftrightarrow \mathrm{a}' \Longleftrightarrow \mathrm{b} \Longleftarrow \mathrm{b}'.$$
If E is pseudo-coherent, then a), a'), b), and b') are equivalent.

The map in b') is obtained as follows. The canonical evaluation arrow $E^\vee \otimes^{\mathbf{L}} E \to \mathcal{O}_X$, tensorized with M, gives an arrow
$$E \otimes^{\mathbf{L}} M \longrightarrow \mathrm{RHom}(E^\vee, M).$$
On H^{p+1}, and then by the canonical map
$$\mathrm{Ext}^{p+1}(E^\vee, M) o \mathrm{Hom}(H^{-p-1}(E^\vee), M),$$
one obtains the arrow b').

Proof. The implications $\mathrm{a}' \Rightarrow \mathrm{a} \Leftrightarrow \mathrm{b} \Leftarrow \mathrm{b}'$ are formal. To prove $\mathrm{a} \Rightarrow \mathrm{a}'$, present M by a sequence $M^0 \to M^1 \to M \to 0$ in which M^0 and M^1 are direct sums of sheaves of the form $\mathcal{O}_{U,X}$, with U an object of X. Right exactness and compatibility with direct sums reduce the assertion to $M = \mathcal{O}_{U,X}$. Then both sides are identified with extension by zero from U, and exactness of that extension gives the result.

Assume now that E is pseudo-coherent and prove $\mathrm{b} \Rightarrow \mathrm{b}'$. It is enough to show that the preceding comparison arrow
$$E \otimes^{\mathbf{L}} M \longrightarrow \mathrm{RHom}(E^\vee, M)$$
is an isomorphism when M is injective. Let $T(F) = F \otimes^{\mathbf{L}} M$ and $T'(F) = \mathrm{RHom}(F^\vee, M)$. Both functors have the same boundedness behaviour under truncation; the arrow is local and is compatible with restriction to opens, and an injective remains injective after such a restriction. After localizing and truncating, one may suppose E strictly perfect. A devissage then reduces to $E = \mathcal{O}_X$, where the assertion is immediate.

Remarks 5.2.

i) Conditions a), a'), b), and b') are local on the topos: if (X_α) is an open covering of the final object and the condition holds for each X_α and $E|X_\alpha$, then it holds on X.

ii) If x is a point of X, write a_x, a'_x, b_x, etc. for the corresponding conditions for E_x and $\mathrm{Mod}(\mathcal{O}_{X,x})$. If X has enough points, condition a), respectively a'), b), is equivalent to the corresponding stalkwise condition for every x; if E is pseudo-coherent, this is also equivalent to b') stalkwise. Moreover, a') may be tested on quotients of modules of the form $\mathcal{O}_{U,x}^{(I)} \to \mathcal{O}_{U,x}$.

iii) The criterion EGA III 7.4.2 extends word for word: if E is represented by flat terms, condition a) says that $\mathrm{Coker}(E^p \to E^{p+1})$ is flat, hence locally a direct factor of a free module of finite type when E^p and E^{p+1} are of finite presentation. In particular, for E perfect, condition a) for degree p is equivalent to the corresponding condition for $E^\vee$ in degree $-p-1$.

iv) Let X be a quasi-separated scheme and let $E \in \mathrm{ob}\, D(X)$ have locally bounded quasi-coherent cohomology. Let a_{qcoh}, a'_{qcoh}, etc. be the analogous conditions with $\mathrm{Mod}(X)$ replaced by $\mathrm{Qcoh}(X)$. Then

$$a \Rightarrow a_{\mathrm{qcoh}}, \qquad a' \Rightarrow a'_{\mathrm{qcoh}}, \qquad b \Rightarrow b_{\mathrm{qcoh}},$$

and these conditions are all equivalent when E is pseudo-coherent. This follows by reducing to affine opens, using II 3.5 and II 2.2.10 a), and the fact that quasi-coherent sheaves extend from affine opens on a quasi-separated scheme.

Proposition 5.3 (exchange property; EGA III 7.7.5 II). Let $f : X \to Y$ be a morphism of quasi-compact and quasi-separated schemes, let $E \in \mathrm{ob}\, D^-(X)$ have quasi-coherent cohomology and finite flat amplitude relative to f, and let $p \in \mathbb{Z}$. Consider:

a) $M \mapsto R^p f_*(E \otimes^{\mathbf{L}}_Y M)$, from $\mathrm{Qcoh}(Y)$ to $\mathrm{Qcoh}(Y)$, is right exact;

a′ the canonical arrow

$$R^p f_*(E) \otimes M \longrightarrow R^p f_*(E \otimes^{\mathbf{L}}_Y M)$$

is an isomorphism for every $M \in \mathrm{ob}\, \mathrm{Qcoh}(Y)$;

b $M \mapsto R^{p+1} f_*(E \otimes^{\mathbf{L}}_Y M)$ is left exact;

b′ the canonical arrow

$$R^{p+1} f_*(E \otimes^{\mathbf{L}}_Y M) \longrightarrow \mathrm{Hom}(H^{-p-1}((Rf_*E)^\vee), M)$$

is an isomorphism for every $M \in \mathrm{ob}\, \mathrm{Qcoh}(Y)$;

c for every base change $Y' \to Y$, the canonical arrow

$$R^p f_*(E) \otimes_Y \mathcal{O}_{Y'} \longrightarrow H^p(Rf_*E \otimes^{\mathbf{L}}_Y \mathcal{O}_{Y'})$$

is an isomorphism.

Then

$$a \iff a' \iff c \iff b \impliedby b'.$$

If, moreover, f is proper, E is pseudo-coherent relative to f (hence perfect relative to f), and (2.1) is valid for f, for instance if f is projective or Y is noetherian, then the preceding conditions are all equivalent.

Proof. The implications among a), a'), b), and b') follow at once from (3.7), (5.1), and (5.2 iv); the implication $b \Rightarrow b'$ in the proper pseudo-coherent case follows from (2.1). It remains to compare a') and c). This is supplied by the following lemma.

Lemma 5.3.1. Let X be a quasi-separated scheme, and let $E \in \mathrm{ob}\, D^-(X)$ have locally bounded quasi-coherent cohomology. Then condition (5.1 a) is equivalent to:

c) for every $X' \to X$, the canonical map

$$H^p(E) \otimes_X \mathcal{O}_{X'} \longrightarrow H^p(E \otimes_X^{\mathbf{L}} \mathcal{O}_{X'})$$

is an isomorphism.

If E is pseudo-coherent, condition (5.1 a) also implies that, for every $X' \to X$, the map

$$H^{-p-1}(E^\vee) \otimes_X \mathcal{O}_{X'} \longrightarrow H^{-p-1}((E \otimes_X^{\mathbf{L}} \mathcal{O}_{X'})^\vee) \tag{5.3.1.1}$$

is an isomorphism.

Proof of the lemma. For $a \Rightarrow c$, localize on X', and assume $X = \operatorname{Spec} A$, $X' = \operatorname{Spec} A'$, and $E = \widetilde{F}$. By the affine case the hypothesis gives

$$H^p(F) \otimes_A A' \longrightarrow H^p(F \otimes_A^{\mathbf{L}} A')$$

an isomorphism, which is exactly c). Conversely, by (5.2 iv) it suffices to prove $c \Rightarrow a'_{\mathrm{qcoh}}$. Again localizing, write $X = \operatorname{Spec} A$, $E = \widetilde{F}$, and let $M = \widetilde{N}$ be quasi-coherent. Taking $A' = D_A(N)$ and applying c) to $\operatorname{Spec} A' \to X$ gives the required map

$$H^p(F) \otimes_A N \longrightarrow H^p(F \otimes_A^{\mathbf{L}} N)$$

as an isomorphism.

For the last assertion, the question is local on X'. By (II 2.2.10 b) and truncation, one may suppose E strictly perfect. Then $(E \otimes_X^{\mathbf{L}} \mathcal{O}_{X'})^\vee$ identifies canonically with $E^\vee \otimes_X^{\mathbf{L}} \mathcal{O}_{X'}$, and (5.3.1.1) is the canonical map

$$H^{-p-1}(E^\vee) \otimes_X \mathcal{O}_{X'} \longrightarrow H^{-p-1}(E^\vee \otimes_X^{\mathbf{L}} \mathcal{O}_{X'}). \tag{$*$}$$

If E satisfies (5.1 a) for p, then by (5.2 iii) $E^\vee$ satisfies the same condition for $-p-1$, and $(*)$ is an isomorphism by the first part of the lemma. The lemma, and therefore (5.3), follow.

Remark 5.3.2. Proposition (5.3) applies in particular when E is a bounded complex of quasi-coherent flat $\mathcal{O}_X$-modules of finite presentation relative to f: by (4.3.2), such a complex has finite perfect amplitude relative to f.

Definition 5.4. Let X be a topos, let $\mathrm{Pt}(X)$ be its set of points (SGA 4 IV 6.1), let M be an ordered set, and let $\varphi : \mathrm{Pt}(X) \to M$ be a function. We say that φ is upper semi-continuous at x (respectively lower semi-continuous, respectively locally constant) if there exists an x-pointed object U of X such that for every point y of U, one has $\varphi(y) \leq \varphi(x)$ (respectively $\varphi(y) \geq \varphi(x)$, respectively $\varphi(y) = \varphi(x)$). We say that φ is upper semi-continuous (respectively lower semi-continuous, respectively locally constant) if it is so at every point.

Examples 5.4.1.

a) If $\underline{M}$ is the constant sheaf with value M and $s \in H^0(X, \underline{M})$, then $x \mapsto x^*s$ is locally constant. In particular, if X is locally ringed and E is a perfect complex on X, the rank of E (I 6.11) defines a locally constant function on $\mathrm{Pt}(X)$ with values in $\mathbb{Z}$.

b) If X is locally ringed and P is an $\mathcal{O}_X$-module of finite type, then for $x \in \mathrm{Pt}(X)$, $P_x \otimes_{\mathcal{O}_{X,x}} k(x)$ is a finite-dimensional vector space over $k(x)$, and

$$x \longmapsto \dim_{k(x)}(P_x \otimes k(x))$$

is upper semi-continuous. This is the usual Nakayama argument: an epimorphism $\mathcal{O}_{X,x}^n \to P_x$ lifts over a pointed neighbourhood.

Lemma 5.5. Let $(X, \mathcal{O}_X)$ be a locally ringed topos, let $E \in \mathrm{ob}\, D(X)$, and let $p \in \mathbb{Z}$. Then:

i) If E is perfect, the vector spaces

$$H^i(E_x \otimes^{\mathbf{L}}_{\mathcal{O}_{X,x}} k(x))$$

are finite-dimensional over $k(x)$, zero except for finitely many i, and the function

$$x \longmapsto \sum_i (-1)^i \dim_{k(x)} H^i(E_x \otimes^{\mathbf{L}} k(x))$$

is locally constant on $\mathrm{Pt}(X)$.

ii) If E is $(p-1)$-pseudo-coherent, then

$$H^p(E_x \otimes^{\mathbf{L}}_{\mathcal{O}_{X,x}} k(x))$$

is finite-dimensional over $k(x)$, and its dimension is upper semi-continuous on $\mathrm{Pt}(X)$. If moreover $M \mapsto H^p(E \otimes^{\mathbf{L}} M)$ is exact on $\mathrm{Mod}(X)$, then $H^p(E)$ is locally free of finite type and the preceding function is locally constant.

iii) If E is p-pseudo-coherent (respectively $(p-1)$-pseudo-coherent), and if for a point x the functor

$$M \longmapsto H^p(E_x \otimes^{\mathbf{L}}_{\mathcal{O}_{X,x}} M)$$

is right exact (respectively left exact) on $\mathrm{Mod}(\mathcal{O}_{X,x})$, then there exists an x-pointed object U such that

$$M \longmapsto H^p(E|_U \otimes^{\mathbf{L}} M)$$

is right exact (respectively left exact) on $\mathrm{Mod}(U)$.

Proof. For i), by I 4.19.1 the complex $E_x \otimes^{\mathbf{L}} k(x)$ is a perfect complex of $k(x)$-modules; hence its cohomology spaces have finite rank and vanish except for finitely many degrees. The identity

$$\mathrm{rank}(E_x \otimes^{\mathbf{L}} k(x)) = \sum_i (-1)^i \dim_{k(x)} H^i(E_x \otimes^{\mathbf{L}} k(x))$$

follows by devissage from the additivity of rank. The assertion follows from the compatibility of the rank with inverse images (I 6.12).

For ii), after truncation and translation, one may assume for the first assertion that E is strictly perfect, $p = 0$, and $E^i = 0$ for $i \notin [-1, 1]$. Put $E(x) = E_x \otimes^{\mathbf{L}} k(x)$. Then

$$0 = \mathrm{rank}(E(x)) = \dim H^{-1}(E(x)) - \dim H^0(E(x)) + \dim H^1(E(x))$$

up to the corresponding alternating-rank convention; hence upper semi-continuity of $\dim H^0(E(x))$ follows from that of the neighbouring cohomology dimensions and from local constancy of the rank of the terms. For H^1 this is immediate from (5.4.1 b). For H^{-1}, replacing E by the truncated complex $(0 \to E^{-1} \to E^0 \to 0)$ reduces to the same argument.

For the second assertion in ii), after truncating one may suppose E strictly perfect and $E^i = 0$ for $i < p-1$. Then $Z'^{p+1}(E) = \mathrm{Coker}(E^p \to E^{p+1})$ is of finite presentation and one has an exact sequence

$$0 \to H^p(E) \to Z'^p(E) \to E^{p+1} \to Z'^{p+1}(E) \to 0.$$

Exactness of $M \mapsto H^p(E \otimes^{\mathbf{L}} M)$ implies, by (5.2 iii), that $Z'^p(E)$ and $Z'^{p+1}(E)$ are flat, hence locally free of finite type by I 5.8.3. The exact sequence then shows that $H^p(E)$ is locally free of finite type, and the function $x \mapsto \dim_{k(x)} H^p(E)_x$ is locally constant.

For iii), one may assume that E is strictly perfect and that $E^i = 0$ for $i < p$ (respectively for $i < p-1$). Saying that the functor

$$M \longmapsto H^p(E_x \otimes^{\mathbf{L}}_{\mathcal{O}_{X,x}} M)$$

is right exact (respectively left exact) on $\mathrm{Mod}(\mathcal{O}_{X,x})$ is equivalent, by (5.2 iii), to saying that $Z'^{p+1}(E_x)$ (respectively $Z'^p(E_x)$) is flat, hence free of finite type since it is of finite presentation. Since

$$Z'^{p+1}(E_x) \simeq Z'^{p+1}(E)_x \qquad (\text{respectively } Z'^p(E_x) \simeq Z'^p(E)_x),$$

the usual argument (EGA 0_I, 5.2.7) gives an x-pointed object U of X on which $Z'^{p+1}(E|_U)$ (respectively $Z'^p(E|_U)$) is locally free of finite type. This proves the exactness assertion.

Corollary 5.6 (EGA III 7.6.9). Let X be a scheme, let $p \in \mathbb{Z}$, and let $E \in \mathrm{ob}\, D^-(X)$ be $(p-1)$-pseudo-coherent. Then:

i) For $x \in X$, $H^p(E \otimes^{\mathbf{L}}_X k(x))$ has finite rank over $k(x)$, and

$$x \longmapsto \dim_{k(x)} H^p(E \otimes^{\mathbf{L}}_X k(x))$$

is constructible and upper semi-continuous on X.

ii) Suppose X is quasi-separated and E has locally bounded quasi-coherent cohomology. If $M \mapsto H^p(E \otimes^{\mathbf{L}} M)$ is exact on the category of quasi-coherent $\mathcal{O}_X$-modules, then the preceding function is locally constant and $H^p(E)$ is locally free of finite type. Conversely, if X is locally noetherian and reduced and that function is locally constant, then the same functor is exact on quasi-coherent modules.

Proof. If X is integral with generic point x, the functor $M \mapsto H^p(E_x \otimes M)$ is exact on $\mathcal{O}_{X,x}$-modules, since $\mathcal{O}_{X,x} = k(x)$. By (5.5 iii) there is a non-empty open neighbourhood U of x on which the corresponding functor is exact, and by (5.5 ii) the rank function is locally constant on U. This gives constructibility. The other assertions follow from (5.5 ii, iii) and (5.2 iv), except for the converse in ii), for which one reduces locally and by truncation to the strictly perfect case and applies EGA III 7.6.2 and 7.6.5 to the functor $T_M = H^p(E \otimes^{\mathbf{L}} M)$.

Proposition 5.7 (EGA III 7.7.5 and 7.9.4). Let $f : X \to Y$ be a proper morphism of quasi-compact schemes, let $E \in \mathrm{ob}\, D(X)_{\mathrm{parf}}$, and let $p \in \mathbb{Z}$. Assuming (2.1) is valid for f, for instance if f is projective or if Y is noetherian, the following hold:

i) For $y \in Y$, the vector spaces $H^i(Rf_*E \otimes^{\mathbf{L}}_Y k(y))$ are finite-dimensional over $k(y)$, zero except for finitely many i, and their alternating rank is locally constant on Y.

ii) The function

$$y \longmapsto \dim_{k(y)} H^p(Rf_*E \otimes^{\mathbf{L}}_Y k(y))$$

is constructible and upper semi-continuous on Y.

iii) Suppose Y is quasi-separated. If $M \mapsto R^p f_*(E \otimes_Y^{\mathbf{L}} M)$ is exact on the category of quasi-coherent $\mathcal{O}_Y$-modules, then $R^p f_*(E)$ is locally free of finite type and the function in ii) is locally constant. Conversely, if Y is noetherian and reduced and the function in ii) is locally constant, then the same functor is exact on quasi-coherent modules.

Proof. By (4.8), $Rf_*(E)$ is a perfect complex. Assertion i), respectively ii), follows from (5.5 i), respectively (5.6 i). If M is quasi-coherent on Y, the canonical arrow

$$Rf_*(E) \otimes_Y^{\mathbf{L}} M \xrightarrow{\sim} Rf_*(E \otimes_Y^{\mathbf{L}} M)$$

is an isomorphism by (3.7), and iii) follows from (5.6 ii).

Remarks 5.8.

a) In the situation of (5.7), let $i_y : X_y \to X$ be the inclusion of the fiber over a point $y \in Y$. One may show, under the usual flatness hypotheses, the Künneth formula

$$H^i(Rf_*E \otimes_Y^{\mathbf{L}} k(y)) \simeq H^i(X_y, E_y),$$

where $E_y = Li_y^*E$, or $E_y = i_y^*E$ in the flat case.

b) One can develop for complex analytic spaces a theory analogous to that of this section: exchange, semi-continuity, and continuity properties. Its essential inputs are Grauert's finiteness theorem for proper morphisms and the analytic analogue of the projection formula. More precisely, for a morphism $f : X \to Y$ of analytic spaces, with X of bounded dimension, and for $E \in \operatorname{ob} D(X)$, $M \in \operatorname{ob} D(Y)_{\mathrm{coh}}$, the canonical arrow

$$Rf_*(E) \otimes_Y^{\mathbf{L}} M \longrightarrow Rf_*(E \otimes_Y^{\mathbf{L}} M)$$

is an isomorphism. Unlike Grauert's theorem, this assertion is essentially formal; it follows by the same devissage as in the proof of (3.7), and requires no hypothesis on E beyond belonging to the appropriate derived category.

Exposé IV. Grothendieck groups of ringed topoi

by L. Illusie

1. Reminders and generalities on Grothendieck groups

1.1. Let C be a triangulated category. Recall that a map f from $\operatorname{ob} C$ to an abelian group G is called *additive* if

$$f(E) = f(E') + f(E'')$$

for every distinguished triangle

$$E' \longrightarrow E \longrightarrow E'' \longrightarrow E'[1].$$

The additive maps from $\operatorname{ob} C$ to G form an abelian group, depending functorially on G. The functor so obtained is represented by an abelian group $k(C)$ and a universal additive map

$$\mathrm{cl}_C : \operatorname{ob} C \longrightarrow k(C),$$

which we shall write simply as cl when no confusion is possible.

The group $k(C)$ depends functorially on C with respect to exact functors. If C, C' are triangulated categories, two isomorphic exact functors from C to C' induce the same homomorphism $k(C) \to k(C')$; in particular, if $u : C \to C'$ is an exact equivalence of categories, then $k(u) : k(C) \to k(C')$ is an isomorphism.

Lemma 1.2. Let C be a triangulated category and let $L \in \operatorname{ob} C$.

a) For every $n \in \mathbb{Z}$,

$$\mathrm{cl}(L[n]) = (-1)^n \,\mathrm{cl}(L).$$

If L', L'' are objects of C such that $L \simeq L' \oplus L''$, then

$$\mathrm{cl}(L) = \mathrm{cl}(L') + \mathrm{cl}(L'').$$

b) Suppose that there exists $n \in \mathbb{Z}$ such that

$$\coprod_{i \geq 0} L[2ni]$$

is representable. Then $\mathrm{cl}(L) = 0$.

Proof. Assertion a) follows directly from the definitions. For b), it is enough to observe that

$$\coprod_{i \geq 0} L[2ni] \simeq L \oplus \left(\coprod_{i \geq 0} L[2ni] \right) [2n],$$

and to apply a).

Lemma 1.3. Let C be a triangulated category and let A be a thick subcategory of C ([V] I 2.1). The inclusion and quotient functors define an exact sequence

$$k(A) \longrightarrow k(C) \longrightarrow k(C/A) \longrightarrow 0.$$

Proof. See SGA 5 VIII 3.1.

Lemma 1.4. Let A be an additive category, respectively an abelian category, and let f be an additive function on $\operatorname{ob} K^b(A)$, respectively on $\operatorname{ob} D^b(A)$. For $E \in \operatorname{ob} K^b(A)$, respectively $E \in \operatorname{ob} D^b(A)$, one has

$$f(E) = \sum_i (-1)^i f(E^i),$$

respectively

$$f(E) = \sum_i (-1)^i f(H^i(E)).$$

Proof. Left as an exercise to the reader.

1.5. Let C be an abelian category and let A be a full subcategory of C, stable under finite sums. A map f from $\operatorname{ob} A$ to an abelian group G is called *additive* if

$$\sum_i (-1)^i f(E^i) = 0$$

for every acyclic bounded complex E of C whose components belong to A. When A is stable under kernels of epimorphisms (I 1.2), this amounts to saying that

$$f(L) = f(L') + f(L'')$$

for every exact sequence

$$0 \longrightarrow L' \longrightarrow L \longrightarrow L'' \longrightarrow 0$$

in C whose terms belong to A. The additive maps from $\operatorname{ob} A$ to G form an abelian group depending functorially on G. Denote by $K^{b,\emptyset}(A)$ the thick subcategory of $K^b(A)$ consisting of acyclic complexes. It follows easily from (1.3) and (1.4) that the map

$$\mathrm{cl}_A : \operatorname{ob} A \longrightarrow k\big(K^b(A)/K^{b,\emptyset}(A)\big) \tag{1.5.1}$$

induced by $\mathrm{cl}_{K^b(A)/K^{b,\emptyset}(A)}$ is a universal additive map, i.e. that the pair

$$\Big(k\big(K^b(A)/K^{b,\emptyset}(A)\big), \mathrm{cl}_A\Big)$$

represents the functor which associates to each abelian group G the abelian group of additive maps from $\operatorname{ob} A$ to G. We put

$$k\big(K^b(A)/K^{b,\emptyset}(A)\big) = k(A), \tag{1.5.2}$$

and write $k(A, C)$ instead of $k(A)$ when it is necessary to avoid ambiguity about the ambient abelian category.[22] In particular, for $A = C$, one has

$$k(D^b(C)) = k(C). \tag{1.5.3}$$

Lemma 1.6. Let C be an abelian category and let A be a thick abelian subcategory, i.e. a full subcategory stable under kernels, cokernels, and extensions. Let $D_A(C)$ be the full subcategory of $D(C)$ formed by the objects E such that $H^i(E) \in \operatorname{ob} A$ for every i. Then $D_A(C)$ is a triangulated subcategory ([V] I 2.3) of $D(C)$, and the canonical functor

$$D^b(A) \longrightarrow D^b_A(C) = D^b(C) \cap D_A(C)$$

induces an isomorphism

$$k(A) \xrightarrow{\sim} k(D^b_A(C)),$$

where $k(A)$ is defined by (1.5.2).

Proof. The first assertion is an immediate consequence of the long exact cohomology sequence. For the second, consider the map

$$f : \operatorname{ob} D^b_A(C) \longrightarrow k(A)$$

defined by

$$f(E) = \sum_i (-1)^i \,\mathrm{cl}_A(H^i(E)).$$

[22] The notation $k(A)$ had been introduced in I 6.3 for the group $k(K^b(A))$, which is not in general isomorphic to the group defined by (1.5.2). We therefore change convention here: in this exposé the notation $k(A)$ will mean only the group defined by (1.5.2).

By the long exact cohomology sequence, f is additive in the sense of (1.1), hence defines a homomorphism

$$\varphi : k(D^b_A(C)) \longrightarrow k(A).$$

It follows at once from (1.4) that φ is inverse to the canonical homomorphism $k(A) \to k(D^b_A(C))$.

Remark 1.6.1. In the situation of (1.6), the canonical functor

$$D^b(A) \longrightarrow D^b_A(C)$$

is not in general an equivalence of categories. This is shown by the example where S is a scheme, C is the category of $\mathcal{O}_S$-modules, and A is the category of quasi-coherent $\mathcal{O}_S$-modules (II App. I 0.3). See, however, the criterion (II 2.1.3).

Definition 1.7. Let C be a triangulated category, respectively an abelian category, and let C' be a subset of $\operatorname{ob} C$. We shall say that C' is an *exact subset* if, for every distinguished triangle

$$E' \longrightarrow E \longrightarrow E'' \longrightarrow E'[1],$$

respectively for every exact sequence

$$0 \longrightarrow E' \longrightarrow E \longrightarrow E'' \longrightarrow 0,$$

such that two of the terms E', E, E'' belong to C', the third also belongs to C'. We shall say that C' is *dense* in $\operatorname{ob} C$ if $\operatorname{ob} C$ is the smallest exact subset of $\operatorname{ob} C$ containing C'.

Lemma 1.8. Let C be a triangulated category, respectively an abelian category, and let C' be a dense subset of $\operatorname{ob} C$. Then the elements $\operatorname{cl}_C(E)$, for $E \in C'$, generate $k(C)$.

Proof. Put $C' = C_0$, and for $i \geq 1$ define C_i recursively as the set of objects of C occurring in a distinguished triangle, respectively a short exact sequence, two of whose terms belong to C_{i-1}. The C_i form an increasing filtration of $\operatorname{ob} C$, which is exhaustive by hypothesis. For $i \geq 0$, let $k(C)_i$ be the subgroup of $k(C)$ generated by the elements $\operatorname{cl}_C(E)$, $E \in C_i$. It is immediate from the definitions that $k(C)_i = k(C)_{i+1}$ for every $i \geq 0$, hence $k(C)_i = k(C)_0$. If $x \in k(C)$, one can write $x = \operatorname{cl}(E') - \operatorname{cl}(E'')$ for $E', E'' \in \operatorname{ob} C$ (in the non-respectable case one may even arrange $E'' = 0$). Since the filtration (C_i) is exhaustive, there exists $i \geq 0$ such that E' and E'' belong to C_i; hence $x \in k(C)_i = k(C)_0$, as required.

Exercise 1.9. Let C be an abelian category and A a full subcategory stable under finite sums, subobjects, and quotients, such that $\operatorname{ob} A$ is dense in $\operatorname{ob} C$. Then the homomorphism

$$k(A, C) \longrightarrow k(C)$$

defined by the additive function $E \mapsto \operatorname{cl}_C(E)$ on $\operatorname{ob} A$ (cf. (1.5)) is an isomorphism.

Hint. Put $A = A_0$, and define A_i, for $i \geq 1$, as the full subcategory of C consisting of objects of C which are extensions of two objects of A_{i-1}. Prove that A_i satisfies the same hypotheses as A, and then prove that the canonical homomorphism

$$\varinjlim_i k(A_i, C) \longrightarrow k(C)$$

is an isomorphism. The desired conclusion follows at once.

2. The functors $K_\bullet$ and K' of a ringed topos

2.1. Let (X, A) be a ringed topos. Recall the following notation:

$$D^b(A_X)_{\mathrm{coh}}$$

is the category of pseudo-coherent complexes with bounded cohomology of left A-modules (I 2.15);

$$D(A_X)_{\mathrm{parf}}$$

is the category of complexes of left A-modules of finite perfect amplitude (I 5.8.4);

$$\mathrm{Loclib}(A_X)$$

is the category of left A-modules locally direct factors of finite free modules (II 2.0);

$$\mathrm{Coh}(A_X)$$

is the category of coherent left A-modules, relative to the category of finite-type free A-modules (I 3.1).

The last two categories are full subcategories of the category $\mathrm{Mod}(A_X)$ of left A-modules, and the first two are full triangulated subcategories of

$$D(A_X) = D(\mathrm{Mod}(A_X)).$$

Definition 2.2. Let (X, A) be a ringed topos. Unless otherwise stated, we shall put

$$K_\bullet(A_X) = k(D^b(A_X)_{\mathrm{coh}}), \qquad K'(A_X) = k(D(A_X)_{\mathrm{parf}}),$$

where $k(\ )$ is defined in (1.1), and

$$K_\bullet(A_X)_{\mathrm{naif}} = k(\mathrm{Coh}(A_X)), \qquad K'(A_X)_{\mathrm{naif}} = k(\mathrm{Loclib}(A_X)),$$

where $k(\ )$ is defined by (1.5.2), the ambient abelian category being $\mathrm{Mod}(A_X)$.[23] We say that $K_\bullet(A_X)$, respectively $K'(A_X)$, is the Grothendieck group of pseudo-coherent, respectively perfect, A-module complexes on X, and that $K_\bullet(A_X)_{\mathrm{naif}}$, respectively $K'(A_X)_{\mathrm{naif}}$, is the Grothendieck group of coherent, respectively locally free, left A-modules.

Remarks 2.3.

a) One can define variants of $K_\bullet(\ )$ and $K'(\ )$ by putting

$$K_\bullet^{\mathrm{loc}}(A_X) = k(D^{\mathrm{loc}b}(A_X)_{\mathrm{coh}}),$$

where "loc b" means "with locally bounded cohomology", and

$$K'_{\mathrm{loc}}(A_X) = k(D(A_X)_{\mathrm{parf}}).$$

These groups coincide with those defined in (2.2) when the final object of X is quasi-compact, but in general they lend themselves less well to computations in intersection theory.

b) The group $K_\bullet(A_X)_{\mathrm{naif}}$ has practically no interest unless A is coherent as a left A-module; otherwise there is a strong risk that very few coherent sheaves exist.

c) Considering the k of triangulated categories which are "too large" is of no interest. Thus, from (1.2 b), one immediately deduces the relations

$$k(D(A_X)) = k(D^-(A_X)) = k(D^+(A_X)) = k(D^b(A_X)) = k(D^-(A_X)_{\mathrm{coh}}) = 0,$$

for the last equality observing that $L \in \mathrm{ob}\, D^-(A_X)_{\mathrm{coh}}$ implies

$$\coprod_{i\geq 0} L[2i] \in \mathrm{ob}\, D^-(A_X)_{\mathrm{coh}}.$$

[23] We shall allow ourselves to omit the index A when no confusion can result. We shall sometimes also drop the index "naive", but will then say so explicitly.

2.4. Case of a coherent sheaf of rings. Let (X, A) be a ringed topos, with A assumed coherent as a left A-module (I 3.1 and 3.6). Every coherent left A-module is a pseudo-coherent complex (I 3.5), and one has a fully faithful functor

$$\mathrm{Coh}(A_X) \longrightarrow D^b(A_X)_{\mathrm{coh}}. \tag{2.4.1}$$

Moreover $\mathrm{Coh}(A_X)$ is a thick subcategory of $\mathrm{Mod}(A_X)$ (I 3.4), and, by (I 3.5), $D^b(A_X)_{\mathrm{coh}}$ is the full subcategory of $D^b(A_X)$ formed by the objects L such that $H^i(L) \in \mathrm{ob}\,\mathrm{Coh}(A_X)$ for all i. Consequently, it follows from (1.6) that the homomorphism

$$K_\bullet(A_X)_{\mathrm{naif}} \longrightarrow K_\bullet(A_X) \tag{2.4.2}$$

defined by (2.4.1) is an isomorphism.

2.5. The homomorphism $K' \to K_\bullet$. Let (X, A) be a ringed topos. The inclusion functor

$$D(A_X)_{\mathrm{parf}} \longrightarrow D^b(A_X)_{\mathrm{coh}}$$

defines a homomorphism

$$K'(A_X) \longrightarrow K_\bullet(A_X). \tag{2.5.1}$$

It is not in general injective or surjective. However, assume the following hypotheses:

(i) the final object of X is quasi-compact;

(ii) X has enough points, and for every point x of X, every left A_x-module has finite Tor-dimension.

Then, by (I 5.10),

$$D(A_X)_{\mathrm{parf}} = D^b(A_X)_{\mathrm{coh}},$$

and (2.5.1) is an isomorphism. The hypotheses (i) and (ii) are satisfied, for example, by a compact space ringed by regular local rings.

2.6. Pairings between K' and K' in the non-commutative case. Let

$$f : (X', A') \longrightarrow (X, A)$$

be a morphism of ringed topoi, and denote by $\mathrm{Mod}(A', X', A)$ the category of bimodules which are left A'-modules and right $f^{-1}(A)$-modules. Let

$$\mathrm{Loclib}^b_A(A', X', A)$$

be the full subcategory formed by the objects which belong, as objects over A', to $\mathrm{Loclib}(A', X')$. By analogy with (2.2), put

$$K'_{\mathrm{naif}}(A', X', A)_{A'} = k(\mathrm{Loclib}^b_A(A', X', A)).$$

Tensor product

$$\otimes_A : \mathrm{Mod}(A', X', A) \times \mathrm{Mod}(A_X) \longrightarrow \mathrm{Mod}(A', X')$$

sends

$$(E', E) \longmapsto E' \otimes_{f^{-1}(A)} f^{-1}(E),$$

and induces a functor

$$\mathrm{Loclib}^b_A(A', X', A) \times \mathrm{Loclib}(A_X) \longrightarrow \mathrm{Loclib}(A', X'). \tag{2.6.1}$$

The map $(E', E) \mapsto \mathrm{cl}(E' \otimes_A E)$ deduced from (2.6.1) is biadditive in the sense of (1.5), and therefore defines a homomorphism

$$K'_{\mathrm{naif}}(A', X', A)_{A'} \otimes K'_{\mathrm{naif}}(A_X) \longrightarrow K'_{\mathrm{naif}}(A', X'). \tag{2.6.2}$$

Let $D^-(A', X', A)$ be the derived category of $\mathrm{Mod}(A', X', A)$, and let

$$D^-(A', X', A)_{A'\text{-}\,\mathrm{parf}}$$

be the full subcategory formed by the complexes of finite perfect amplitude relative to A', i.e. as objects of $D^-(A', X')$. Put, as in (2.2),

$$K'(A', X', A)_{A'} = k(D^-(A', X', A)_{A'\text{-}\,\mathrm{parf}}).$$

The inclusion functors define evident homomorphisms

$$K'_{\mathrm{naif}}(A', X', A)_{A'} \longrightarrow K'(A', X', A)_{A'}, \tag{2.6.3.1}$$
$$K'_{\mathrm{naif}}(A_X) \longrightarrow K'(A_X), \tag{2.6.3.2}$$
$$K'_{\mathrm{naif}}(A', X') \longrightarrow K'(A', X'). \tag{2.6.3.3}$$

On the other hand, one knows (I 4.18, 4.19) that the derived tensor functor

$$\otimes^{\mathbf{L}}_A : D^-(A', X', A) \times D^-(A_X) \longrightarrow D^-(A', X')$$

induces an exact functor

$$D^-(A', X', A)_{A'\text{-}\,\mathrm{parf}} \times D(A_X)_{\mathrm{parf}} \longrightarrow D(A', X')_{\mathrm{parf}}. \tag{2.6.4}$$

The latter defines a homomorphism

$$K'(A', X', A)_{A'} \otimes K'(A_X) \longrightarrow K'(A', X'). \tag{2.6.5}$$

Since (2.6.1) is induced by (2.6.4), the homomorphisms (2.6.2) and (2.6.5) are compatible with the homomorphisms (2.6.3.1), (2.6.3.2), and (2.6.3.3), in other words one has a commutative diagram

$$\begin{array}{ccc} K'_{\mathrm{naif}}(A', X', A)_{A'} \otimes K'_{\mathrm{naif}}(A_X) & \to & K'_{\mathrm{naif}}(A', X') \\ \downarrow & & \downarrow \\ K'(A', X', A)_{A'} \otimes K'(A_X) & \longrightarrow & K'(A', X'), \end{array} \tag{2.6.6}$$

where the upper and lower horizontal arrows are respectively (2.6.2) and (2.6.5), and the vertical arrows are defined by (2.6.3.1), (2.6.3.2), and (2.6.3.3).

2.7. Contravariant law and ring structure on K'. We spell out some important particular cases of the pairings (2.6), although their direct study is immediate.

a) Let

$$f : (X', A') \longrightarrow (X, A)$$

be a morphism of ringed topoi. The functor

$$Lf^* : D^-(A_X) \longrightarrow D^-(A', X')$$

sends $D(A_X)_{\mathrm{parf}}$ to $D(A', X')_{\mathrm{parf}}$ (I 4.19.1), and likewise sends $\mathrm{Loclib}(A_X)$ to $\mathrm{Loclib}(A', X')$. Thus it defines a homomorphism

$$f^* : K'(A_X) \longrightarrow K'(A', X') \tag{2.7.1}$$

and, respectively,

$$f^* : K'(A_X)_{\mathrm{naif}} \longrightarrow K'(A', X')_{\mathrm{naif}}. \tag{2.7.2}$$

This can also be interpreted as multiplication by $\mathrm{cl}(A')$ in (2.6.2), respectively (2.6.5). One has a commutative diagram, a special case of (2.6.6),

$$\begin{array}{ccc} K'(A_X)_{\mathrm{naif}} & \xrightarrow{f^*} & K'(A', X')_{\mathrm{naif}} \\ \downarrow & & \downarrow \\ K'(A_X) & \xrightarrow{f^*} & K'(A', X'), \end{array}$$

where the left and right vertical arrows are respectively (2.6.3.2) and (2.6.3.3).

Let $g : (X, A) \to (X'', A'')$ be a morphism of ringed topoi. The transitivity of inverse-image functors implies that the homomorphisms of type (2.7.1), respectively (2.7.2), satisfy

$$(gf)^* = f^* g^*. \tag{2.7.3}$$

Thus $K'(A_X)$, respectively $K'(A_X)_{\mathrm{naif}}$, is a contravariant functor of (X, A).

b) Let $(X, \mathcal{O}_X)$ be a commutatively ringed topos. Thanks to the associativity and commutativity of tensor product, (2.6.5), respectively (2.6.2), with $A = \mathcal{O}_X$, $(X', A') = (X, A)$, and $f = \mathrm{Id}$, endows $K'(X)$, respectively $K'(X)_{\mathrm{naif}}$, with the structure of a commutative ring with unit

$$1 = \mathrm{cl}(\mathcal{O}_X).$$

The canonical homomorphism

$$K'(X)_{\mathrm{naif}} \longrightarrow K'(X)$$

is a homomorphism of unital rings.

If $f : (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ is a morphism of commutatively ringed topoi, compatibility of tensor product with inverse image shows that

$$f^* : K'(Y) \longrightarrow K'(X),$$

respectively

$$f^* : K'(Y)_{\mathrm{naif}} \longrightarrow K'(X)_{\mathrm{naif}},$$

is a homomorphism of unital rings.

2.8. Augmentation of K' toward $H^0(\ , \mathbb{Z})$. Let $(X, \mathcal{O}_X)$ be a locally ringed topos (I 2.15.1). Recall that one has defined (I 6.11 to 6.14) a homomorphism of unital rings

$$i : H^0(X, \mathbb{Z}) \longrightarrow K'(X)_{\mathrm{naif}},$$

thereby endowing $K'(X)_{\mathrm{naif}}$, and then $K'(X)$ through the canonical homomorphism $K'(X)_{\mathrm{naif}} \to K'(X)$, with the structure of a unital algebra over $H^0(X, \mathbb{Z})$. Moreover, $K'(X)_{\mathrm{naif}}$, respectively $K'(X)$, is augmented toward $H^0(X, \mathbb{Z})$ by the rank, and the canonical homomorphism $K'(X)_{\mathrm{naif}} \to K'(X)$ is a homomorphism of augmented algebras.

If $f : (X, \mathcal{O}_X) \to (Y, \mathcal{O}_Y)$ is a morphism of locally ringed topoi, the homomorphisms

$$f^* : K'(Y) \longrightarrow K'(X), \qquad f^* : K'(Y)_{\mathrm{naif}} \longrightarrow K'(X)_{\mathrm{naif}}$$

are compatible (I 6.12, 6.13) with the preceding augmented-algebra structures; this is expressed by the commutativity of the diagram, where rg denotes the rank,

$$\begin{array}{ccccccc} H^0(Y,\mathbb{Z}) & \xrightarrow{i} & K'(Y)_{\text{naif}} & \to & K'(Y) & \xrightarrow{\text{rg}} & H^0(Y,\mathbb{Z}) \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ H^0(X,\mathbb{Z}) & \xrightarrow{i} & K'(X)_{\text{naif}} & \to & K'(X) & \xrightarrow{\text{rg}} & H^0(X,\mathbb{Z}). \end{array}$$

Later in the Seminar (V 3.9.1 and VI) one will see that $K'(X)_{\text{naif}}$ can be endowed with a structure richer than that of an algebra augmented toward $H^0(X,\mathbb{Z})$, namely with a structure of a λ-algebra augmented toward $H^0(X,\mathbb{Z})$, viewed as a binomial ring (V 2.8), this structure being compatible with inverse-image homomorphisms. Deligne has recently proved that $K'(X)$ can be endowed with an analogous structure, at least when X is of characteristic $p \geq 0$, and that the canonical homomorphism

$$K'(X)_{\text{naif}} \longrightarrow K'(X)$$

is a homomorphism of augmented λ-algebras, thereby answering affirmatively a conjecture of Grothendieck (XIV 1).

2.9. Comparison of K' and K'_{naif}. Let (X,A) be a ringed topos. There is in general no reason for the canonical homomorphism

$$K'(X)_{\text{naif}} \longrightarrow K'(X)$$

to be injective or surjective. However, the "global resolution existence criteria" of Exposé II show that it is an isomorphism in the following cases:

(i) X is the Zariski topos of a separated or noetherian divisorial scheme, and $A = \mathcal{O}_X$ (II 2.2.9);

(ii) X is the topos defined by a compact space and A is a soft sheaf (II 2.3.2);

(iii) X is a Stein topos whose final object is quasi-compact and $A = \mathcal{O}_X$ (II 2.4.5).

2.10. Pairing between K' and $K_\bullet$. Let $(X,\mathcal{O}_X)$ be a commutatively ringed topos. One knows (I 5.8.4 b) that there is a pairing

$$\otimes^{\mathbf{L}}_{\mathcal{O}_X} : D(X)_{\text{parf}} \times D^b(X)_{\text{coh}} \longrightarrow D^b(X)_{\text{coh}}.$$

It defines a homomorphism

$$K'(X) \otimes K_\bullet(X) \longrightarrow K_\bullet(X). \tag{2.10.1}$$

Thanks to associativity of tensor product, (2.10.1) endows $K_\bullet(X)$ with the structure of a $K'(X)$-module. More generally, if

$$f : (X,\mathcal{O}_X) \longrightarrow (Y,\mathcal{O}_Y)$$

is a morphism of commutatively ringed topoi, $K_\bullet(X)$ may be regarded as a $K'(Y)$-module through the homomorphism

$$f^* : K'(Y) \longrightarrow K'(X).$$

2.11. Covariant law on $K_\bullet$ and projection formula. Let (X,A) be a ringed topos. In contrast with $K'(A_X)$, the group $K_\bullet(A_X)$ has no natural variance with respect to (X,A). Nevertheless, in algebraic geometry and analytic geometry, $K_\bullet(X)$ tends to be covariant in X for proper morphisms. We now make this precise.

2.11.1. Let $f : X \to Y$ be a proper and pseudo-coherent morphism (III 1.2) of quasi-compact schemes. Then, subject to the validity of the finiteness conjecture for f (III 2.1), hence in particular if Y is noetherian (in which case the pseudo-coherence hypothesis on f is automatically verified (III 1.3)) or if f is projective, the functor Rf_* induces, by (III 2.6), a functor

$$Rf_* : D^b(X)_{\mathrm{coh}} \longrightarrow D^b(Y)_{\mathrm{coh}}.$$

It therefore defines a homomorphism

$$f_* : K_\bullet(X) \longrightarrow K_\bullet(Y). \tag{2.11.1.1}$$

This homomorphism is $K'(Y)$-linear (cf. (2.10)); in other words, for $y \in K'(Y)$ and $x \in K_\bullet(X)$, one has the *projection formula*

$$f_*(yx) = y f_*(x). \tag{2.11.1.2}$$

Indeed, if $x = \mathrm{cl}(E)$ for $E \in \mathrm{ob}\, D^b(X)_{\mathrm{coh}}$ and $y = \mathrm{cl}(M)$ for $M \in \mathrm{ob}\, D(Y)_{\mathrm{parf}}$, then by (III 3.7) one has

$$Rf_*(E) \otimes_Y^{\mathbf{L}} M \simeq Rf_*(E \otimes_Y^{\mathbf{L}} M).$$

Finally, if $g : Y \to Z$ is a proper morphism satisfying the same hypotheses as f, and for which the finiteness conjecture (III 2.1) is true, the transitivity of direct-image functors gives, for the homomorphisms (2.11.1.1), the formula

$$g_* f_* = (gf)_*. \tag{2.11.1.3}$$

2.11.2. Let $f : X \to Y$ be a proper morphism of finite-dimensional analytic spaces. Then, by Grauert's finiteness theorem [2], Rf_* sends $D^b(X)_{\mathrm{coh}}$ into $D^b(Y)_{\mathrm{coh}}$, and hence defines a homomorphism

$$f_* : K_\bullet(X) \longrightarrow K_\bullet(Y). \tag{2.11.2.1}$$

Like its algebraic analogue (2.11.1.1), this homomorphism is $K'(Y)$-linear; equivalently, formula (2.11.1.2) is valid, as follows from the projection formula at the level of derived categories (III 5.9 b). One also has the transitivity formula (2.11.1.3).

2.11.3. Outside the algebraic or analytic framework, this covariance of $K_\bullet$ for proper morphisms disappears. For instance, let

$$f : X \to Y$$

be a proper morphism of topological spaces ringed by the sheaves of complex continuous functions. Then, if $E \in \mathrm{ob}\, D^b(X)_{\mathrm{coh}}$, in general $Rf_*(E)$ need not belong to $D^b(Y)_{\mathrm{coh}}$, as is already evident for $E = \mathcal{O}_X$ and Y reduced to a point. In fact, the definition (2.2) of $K_\bullet$ is especially adapted to the needs of algebraic and analytic geometry, and a good definition of $K_\bullet$ for a topological space remains to be found. It seems, moreover, that one will have to leave the framework of $\mathcal{O}_X$-linear complexes, and define, for a morphism $f : X \to Y$ of topological spaces, or of mixed varieties (II App. II), a suitable class of complexes of topological vector-sheaves on X, meant to contain, when f is the structural morphism of a mixed variety, the elliptic complexes on X relative to Y. This is suggested by the finiteness theorem (II App. II), as well as by the analogous theorem, where Y is assumed reduced to a point, proved by Grothendieck in [3].

2.12. Unusual variances of K' and $K_\bullet$. Let

$$f : (X, A) \longrightarrow (Y, B)$$

be a morphism of finite Tor-dimension of ringed topoi (III 3.1). The functor

$$Lf^* : D^-(B_Y) \longrightarrow D^-(A_X)$$

sends $D^b(B_Y)_{\mathrm{coh}}$ into $D^b(A_X)_{\mathrm{coh}}$ (I 2.16.1), and therefore defines a homomorphism

$$f^* : K_\bullet(B_Y) \longrightarrow K_\bullet(A_X). \tag{2.12.1}$$

If A and B are commutative, commutation of inverse image with tensor product shows that (2.12.1) is compatible with the module structures of $K_\bullet(Y)$ and $K_\bullet(X)$ over $K'(Y)$ and $K'(X)$ respectively (2.10). In other words, for $a \in K'(Y)$ and $y \in K_\bullet(Y)$, one has

$$f^*(ay) = af^*(y). \tag{2.12.2}$$

If $g : (Y, B) \to (Z, C)$ is a morphism of finite Tor-dimension of ringed topoi, transitivity of inverse-image functors implies that the homomorphisms (2.12.1) satisfy

$$f^*g^* = (gf)^*. \tag{2.12.1.1}$$

Now suppose that we are in the situation of (2.11.1), respectively (2.11.2), with f of finite Tor-dimension. Then by (III 4.8.1 and 5.9 b), the functor Rf_* sends $D(X)_{\mathrm{parf}}$ into $D(Y)_{\mathrm{parf}}$, and hence defines a homomorphism

$$f_* : K'(X) \longrightarrow K'(Y). \tag{2.12.3}$$

This is not generally a ring homomorphism. Nevertheless, for $y \in K_\bullet(Y)$, respectively $K'(Y)$, and $x \in K'(X)$, one has

$$f_*(f^*(y)x) = yf_*(x), \tag{2.12.4}$$

where f^* is the homomorphism (2.12.1), respectively (2.7.1). The proof is analogous to that of (2.11.1.2). If $g : Y \to Z$ is a morphism satisfying the same hypotheses as f, the homomorphisms (2.12.3) satisfy the transitivity formula

$$g_*f_* = (gf)_*. \tag{2.12.3.1}$$

The homomorphism (2.12.3) is one of the essential ingredients of the Riemann–Roch theorem, both in algebraic geometry and in analytic geometry, for the indications in the analytic case see Exposé 0, 5.

Suppose that X and Y are separated and divisorial schemes (II 2.2.5), for example schemes possessing ample invertible sheaves. Then (2.9 (i)) identifies $K'(X)$, respectively $K'(Y)$, with $K'(X)_{\mathrm{naif}}$, respectively $K'(Y)_{\mathrm{naif}}$, and (2.12.3) therefore defines a homomorphism

$$f_* : K'(X)_{\mathrm{naif}} \longrightarrow K'(Y)_{\mathrm{naif}}. \tag{2.12.3'}$$

As was already explained in Exposé 0, 3.1, the definition of (2.12.3') was far from evident a priori. In practice, it is precisely one of the main motivations of this Seminar, from Exposé I through Exposé IV.

3. Complements on Grothendieck groups of schemes

The results of this section will not be used in Exposés V to VIII.

Proposition 3.1.0. Let

$$\begin{array}{ccc} X' & \xrightarrow{g} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow[h]{} & Y \end{array}$$

be a cartesian square of schemes, where Y is quasi-compact and f is quasi-compact and quasi-separated. Let $E \in \mathrm{ob}\, D^b(X)$ be a complex with quasi-coherent cohomology. Suppose that X and Y' are Tor-independent over Y (III 1.5). Suppose also either that h has finite Tor-dimension, or that E has finite flat amplitude relative to f. Under these conditions, the base-change arrow

$$Lh^*\, Rf_*E \longrightarrow Rf'_*\, Lg^*E$$

is defined and is an isomorphism.

Proof. To define the arrow, one uses the trivial duality formula (SGA 4 XVII 2.3) for h, which says that there is a canonical functorial isomorphism

$$\mathrm{Hom}(Lh^*L, M) \xrightarrow{\sim} \mathrm{Hom}(L, Rh_*M)$$

for $L \in \mathrm{ob}\, D^-(Y)$ and $M \in \mathrm{ob}\, D^+(Y')$. Using (III 3.5.2) and (III 3.7.1), one easily verifies that one may take $L = Rf_*E$ and $M = Rf'_*Lg^*E$, so that applying this formula reduces the problem to defining an arrow

$$Rf_*E \longrightarrow Rf_*Rg_*Lg^*E.$$

For this arrow we take the image under Rf_* of the adjunction map

$$E \longrightarrow Rg_*Lg^*E,$$

which comes from the trivial duality formula for g. The base-change arrow is therefore defined.

It remains to show that it is an isomorphism. For this, one may first suppose that Y and Y' are affine. Then, by the Leray spectral sequence of an open covering of X, one is reduced to the case where X and X' are affine. One thus has a cartesian square of rings

$$\begin{array}{ccc} B & \longrightarrow & B' \\ \uparrow & & \uparrow \\ A & \longrightarrow & A', \end{array}$$

and one may suppose that E is defined by a bounded-above complex of B-modules. The Tor-independence of A' and B over A, written

$$B \otimes^{\mathbf{L}}_A A' \xrightarrow{\sim} B',$$

then implies, in $D(A')$,

$$E \otimes^{\mathbf{L}}_A A' \xrightarrow{\sim} E \otimes^{\mathbf{L}}_B B',$$

which proves the proposition.

Translating (3.1.0) into terms of Grothendieck groups gives:

Proposition 3.1.1. In the cartesian square of schemes

$$\begin{array}{ccc} X' & \xrightarrow{g} & X \\ {\scriptstyle f'}\downarrow & & \downarrow{\scriptstyle f} \\ Y' & \xrightarrow[h]{} & Y, \end{array}$$

suppose that Y and Y' are quasi-compact, that X and Y' are Tor-independent over Y (III 1.5), that f is proper and pseudo-coherent, and that the finiteness conjecture (III 2.1) is valid for f and f', for example if Y and Y' are noetherian, or if f is projective. Then, if f is perfect, respectively if h has finite Tor-dimension, for $x \in K'(X)$, respectively $x \in K_\bullet(X)$, one has

$$h^* f_*(x) = f'_* g^*(x),$$

where h^*, g^* are defined by (2.7.1), respectively (2.12.1), and f_*, f'_* by (2.12.3), respectively (2.11.1.1). Notice that by (III 4.7.1) f' is perfect if f is, and by (III 3.5.1) g has finite Tor-dimension if h does.

3.2. Passage to the limit on K'_{naif} and $K_\bullet$. Let $(X_i, f_{ij})_{i\in I}$ be a filtered projective system of quasi-compact and quasi-separated schemes whose transition morphisms are affine (cf. EGA IV 8.2.2). Put

$$X = \varprojlim_i X_i,$$

and let $f_i : X \to X_i$ denote the canonical morphism.

3.2.1. The homomorphisms (2.7.2)

$$f_i^* : K'(X_i)_{\mathrm{naif}} \longrightarrow K'(X)_{\mathrm{naif}}$$

define, by the transitivity formula (2.7.3), a homomorphism

$$\varinjlim_i K'(X_i)_{\mathrm{naif}} \longrightarrow K'(X)_{\mathrm{naif}}. \tag{3.2.1.1}$$

I say that this homomorphism is an isomorphism. Indeed, let E be a locally free $\mathcal{O}_X$-module of finite type. By EGA IV 8.5.2 and 8.5.5, there exists an index i and a locally free $\mathcal{O}_{X_i}$-module of finite type E_i such that

$$E \simeq f_i^*(E_i).$$

By EGA IV 8.5.2.5, the image of $\mathrm{cl}(E_i)$ in $\varinjlim_i K'(X_i)_{\mathrm{naif}}$ does not depend on the choice of E_i; denote it by $u(E)$. By EGA IV 8.5.2 and 8.5.6, the map

$$u : \mathrm{ob}\,\mathrm{Loclib}(X) \longrightarrow \varinjlim_i K'(X_i)_{\mathrm{naif}}$$

so defined is additive in the sense of (1.5). It therefore defines a homomorphism

$$K'(X)_{\mathrm{naif}} \longrightarrow \varinjlim_i K'(X_i)_{\mathrm{naif}},$$

and one verifies immediately, using EGA IV 8.5.2, that it is inverse to (3.2.1.1). This proves the assertion.

3.2.2. Likewise one defines a canonical homomorphism

$$\varinjlim_i K'(X_i) \longrightarrow K'(X). \tag{3.2.2.1}$$

Using Deligne's localization technique (SGA 4 XVII), which implies that the category of perfect complexes on X is equivalent to the category

$$\varinjlim_i \mathrm{Parf}(X_i)$$

of the analogous categories of perfect complexes on the X_i, one proves again that (3.2.2.1) is an isomorphism.

3.2.3. Suppose that the X_i, and X, are noetherian, and that the morphisms f_i are flat (then so are the f_{ij}). Then the homomorphisms (2.12.1)

$$f_i^* : K_\bullet(X_i) \longrightarrow K_\bullet(X)$$

define an isomorphism

$$\varinjlim_i K_\bullet(X_i) \xrightarrow{\sim} K_\bullet(X).$$

The proof is analogous to that of (3.2.1), using the fact (2.4) that $K_\bullet(X) \simeq K_\bullet(X)_{\mathrm{naif}}$ is computed in terms of coherent sheaves on X.

Moreover, the module structures of the $K_\bullet(X_i)$ over the $K'(X_i)_{\mathrm{naif}}$ are compatible with the inverse images f_{ij}^* by (2.7.1) and (2.12.2). Passing to the limit, one finds that $\varinjlim_i K_\bullet(X_i)$ is a module over $\varinjlim_i K'(X_i)_{\mathrm{naif}}$; this is compatible, through the isomorphisms (3.2.1.1) and (3.2.2.1), with the module structure of $K_\bullet(X)$ over $K'(X)_{\mathrm{naif}}$. In other words, one has a commutative diagram

$$\begin{array}{ccc} \varinjlim K'(X_i)_{\mathrm{naif}} \otimes \varinjlim K_\bullet(X_i) & \to & \varinjlim K_\bullet(X_i) \\ \downarrow \sim & & \downarrow \sim \\ K'(X)_{\mathrm{naif}} \otimes K_\bullet(X) & \longrightarrow & K_\bullet(X). \end{array}$$

3.3. Relative Grothendieck groups.

3.3.1. Let

$$f : X \longrightarrow Y$$

be a morphism of schemes locally of finite type. Put

$$K'(f) = k(D(f)_{\mathrm{parf}}), \qquad K_\bullet(f) = k(D^b(f)_{\mathrm{coh}}),$$

where $D^b(f)_{\mathrm{coh}}$ denotes the category of complexes which are pseudo-coherent relative to f and have bounded cohomology (III 1.2), and $D(f)_{\mathrm{parf}}$ the category of complexes of finite perfect amplitude relative to f (III 4.2). When there is no possible ambiguity, we shall sometimes write $K'(X/Y)$, respectively $K_\bullet(X/Y)$, instead of $K'(f)$, respectively $K_\bullet(f)$.

The groups $K'(f)$ and $K_\bullet(f)$ do not possess the rich structure of their absolute analogues $K'(X)$ and $K_\bullet(X)$, for tensor product does not in general define homomorphisms

$$K'(f) \otimes K'(f) \longrightarrow K'(f), \qquad K'(f) \otimes K_\bullet(f) \longrightarrow K_\bullet(f).$$

On the other hand, they satisfy interesting variance properties, which we now review.

3.3.2. Let

$$\begin{array}{ccc} X & \xrightarrow{\quad f \quad} & Y \\ & {\scriptstyle h}\searrow \quad \swarrow{\scriptstyle g} & \\ & S & \end{array}$$

be a commutative triangle of morphisms locally of finite type of schemes.

3.3.2.1. If g is pseudo-coherent, one has

$$K_\bullet(f) = K_\bullet(h)$$

(III 1.12). If g is smooth and X quasi-compact, one has

$$K'(f) = K'(h)$$

(III 4.4.1).

3.3.2.2. By (III 1.11 and 4.5), the functor $\otimes_Y^{\mathbf{L}}$ defines pairings

$$D(f)_{\mathrm{parf}} \times D^b(g)_{\mathrm{coh}} \longrightarrow D^b(h)_{\mathrm{coh}},$$

$$D(f)_{\mathrm{parf}} \times D(g)_{\mathrm{parf}} \longrightarrow D(h)_{\mathrm{parf}},$$

which induce homomorphisms

$$K'(f) \otimes K_\bullet(g) \longrightarrow K_\bullet(h),$$

$$K'(f) \otimes K'(g) \longrightarrow K'(h).$$

In particular, taking $X = Y$ and $f = \mathrm{Id}$, one deduces that $K_\bullet(g)$ is a $K'(Y)$-module. On the other hand, if f is perfect, product by

$$\mathrm{cl}(\mathcal{O}_X) \in K'(f)$$

defines $K'(Y)$-linear homomorphisms

$$f^* : K_\bullet(Y/S) \longrightarrow K_\bullet(X/S),$$

and

$$f^* : K'(Y/S) \longrightarrow K'(X/S).$$

3.3.2.3. Suppose S quasi-compact, X and Y of finite type over S, and f proper. Then, subject to the validity of the finiteness conjecture (III 2.1), in particular if Y is noetherian or if f is projective, the functor Rf_* sends $D^b(h)_{\mathrm{coh}}$ into $D^b(g)_{\mathrm{coh}}$, and therefore defines a homomorphism

$$f_* : K_\bullet(X/S) \longrightarrow K_\bullet(Y/S).$$

If in addition f is perfect, Rf_* sends $D(h)_{\mathrm{parf}}$ into $D(g)_{\mathrm{parf}}$ (III 4.8), and defines a homomorphism

$$f_* : K'(X/S) \longrightarrow K'(Y/S).$$

From the projection formula (III 3.7) one deduces

$$f_*(ax) = af_*(x),$$

for f proper, $a \in K'(S)$, $x \in K_\bullet(X)$, respectively for f proper and perfect, $a \in K_\bullet(S)$, $x \in K'(X/S)$.

3.3.2.4. Suppose S noetherian, X and Y of finite type over S, and f compactifiable and perfect. Then by (III 4.9.1), the functor $f^!$ sends $D(g)_{\mathrm{parf}}$ into $D(h)_{\mathrm{parf}}$, and defines a homomorphism

$$f^! : K'(Y/S) \longrightarrow K'(X/S).$$

3.3.3. Under the hypotheses of (III 4.7), the functor $\otimes^{\mathbf{L}}_S$ defines pairings

$$D(f_1)_{\mathrm{parf}} \times D^b(f_2)_{\mathrm{coh}} \longrightarrow D^b(f)_{\mathrm{coh}},$$

$$D(f_1)_{\mathrm{parf}} \times D(f_2)_{\mathrm{parf}} \longrightarrow D(f)_{\mathrm{parf}},$$

which induce homomorphisms

$$K'(f_1) \otimes K_\bullet(f_2) \longrightarrow K_\bullet(f),$$

$$K'(f_1) \otimes K'(f_2) \longrightarrow K'(f).$$

Of course, for $X_i = Y_i = S$, one recovers the $K'(S)$-module structure on $K_\bullet(S)$.

If X is flat over S, one deduces, for $n \geq 1$, homomorphisms

$$K'(X/S)^{\otimes n} \longrightarrow K'((X/S)^n),$$

which should, in a sense, replace the absent ring structure on $K'(X/S)$.

Exposé V. Generalities on λ-rings

by P. Berthelot

The theory of λ-rings is useful whenever one uses rings such as the ring of classes of vector bundles on a ringed site, the representation ring of a group, and so on, for which the exterior-power operations define maps λ^i. We shall use it abundantly later in the Seminar. It is therefore necessary first to develop the general formalism. This exposé is accordingly entirely independent of the rest of the Seminar, and may be useful to users of λ-rings outside algebraic geometry.

The first paragraph essentially gives the theory of Hirzebruch's "multiplicative sequences of polynomials" (cf. [2]). Besides its generality, the functorial viewpoint adopted here has the advantage of considerably reducing the calculations. The following paragraphs will show how, to every augmented λ-ring, one can associate a "Chern ring" which permits the development of a theory of Chern classes. This is the theory which will allow us to state the Riemann–Roch theorem in the general form of Exposé VIII.

1. Universal polynomials

1.1. Let K be a commutative ring with unit, fixed throughout this paragraph. Let $\mathcal{C}$ denote the category of filtered commutative K-algebras with unit, whose filtration is decreasing and such that the group of elements of filtration zero is the whole algebra. We define on $\mathcal{C}$ a functor with values in the category of abelian groups as follows. If $A \in \mathrm{Ob}(\mathcal{C})$, associate to A the set of formal series $\psi \in A[[t]]$ satisfying the following conditions: if

$$\psi = a_0 + a_1 t + \cdots + a_n t^n + \cdots ,$$

then

$$a_0 = 1, \qquad \forall i \geq 1, \quad a_i \in \mathrm{Fil}^i A. \tag{1.1.1}$$

This set will be denoted $\widehat{G}_K(A)$, or $\widehat{G}(A)$ when no confusion is possible. It is clearly an abelian group for multiplication of formal series, and this defines a functor

$$\widehat{G}_K : K\text{-Alg.fil.} \longrightarrow \mathrm{Ab}.$$

If A has the gross filtration, then $\widehat{G}(A)$ is the group of formal series with augmentation 1, which will also be denoted

$$1 + A[[t]]^+.$$

Lemma 1.2. The functor $\widehat{G}_K$ is representable.

Let $(X_i)_{i\in\mathbb{N},\ i\geq 1}$ be a family of indeterminates. Assign to X_i the weight i, and filter the ring $K[X_i]_{i\geq 1}$ by weights with respect to the X_i. One then obtains a bijection

$$\widehat{G}_K(A) \xrightarrow{\sim} \mathrm{Hom}_{K\text{-Alg.fil.}}(K[X_i]_{i\geq 1}, A)$$

by associating to every series

$$\psi = 1 + a_1 t + \cdots + a_n t^n + \cdots \in \widehat{G}_K(A)$$

the morphism f_ψ determined by $f_\psi(X_i) = a_i$. This homomorphism is compatible with the filtrations, and one thus obtains an isomorphism of functors.

Put

$$\varphi = 1 + X_1 t + \cdots + X_n t^n + \cdots .$$

For every filtered K-algebra A and every series $\psi \in \widehat{G}(A)$, there exists a unique homomorphism

$$f_\psi \in K[X_i]_{i\geq 1} \longrightarrow A$$

such that

$$\widehat{G}(f_\psi)(\varphi) = \psi.$$

1.3. For every $A \in \mathrm{Ob}(\mathcal{C})$ we define a filtration on $\widehat{G}(A)$ as follows: a series

$$\psi = 1 + a_1 t + \cdots$$

is said to be of filtration $\geq k$ if $a_i = 0$ for $1 \leq i < k$. Let $F^k\widehat{G}(A)$ be the subgroup so obtained. This is a functor on $\mathcal{C}$, and from now on we shall regard $\widehat{G}$ as a functor with values in the category Ab fil of filtered abelian groups by means of this filtration, with $F^0\widehat{G} = \widehat{G}$.

Let H be a functor on $\mathcal{C}$ with values in Ab fil. We shall suppose that H satisfies the following two conditions:

i) $\forall A \in \mathrm{Ob}(\mathcal{C})$, $H(A)$ is separated and complete,

ii) if $A \in \mathrm{Ob}(\mathcal{C})$ is a graded K-algebra, with the filtration associated to its grading, and if a finite group G acts on A by graded morphisms, then $H(A^G) \simeq H(A)^G$.

Here $H(A)^G$ denotes the invariants under G.

In fact we shall need these conditions only when A is a polynomial ring and G is a finite product of symmetric groups acting by permutation of the indeterminates.

Examples.

1) $H(A) = \widehat{G}(A)$,
2) $H(A) = 1 + A[[t]]^+$.

The latter functor will be denoted $\widehat{G}_g$, with g standing for "gross". Finally,

3) $H(A) = \widehat{G}_a(A)$,

where $\widehat{G}_a(A)$ denotes the group, for addition, of formal series

$$a = a_0 + a_1 t + \cdots$$

such that $a_0 = 0$ and $a_i \in \mathrm{Fil}^i A$ for $i \geq 1$, endowed with the filtration analogous to that on $\widehat{G}$.

1.4. For every n, denote by f_n the endomorphism of $K[X_1, \ldots, X_n]$ defined by

$$f_n(X_i) = X_i \quad (i < n), \qquad f_n(X_n) = 0.$$

It factors through the inclusion of $K[X_1, \ldots, X_{n-1}]$ in $K[X_1, \ldots, X_n]$. Hence the homomorphism

$$H(K[X_1, \ldots, X_{n-1}]) \longrightarrow H(K[X_1, \ldots, X_n])$$

is injective. This will allow us to identify the first group with a subgroup of the second; similarly, we shall regard $H(K[X_1, \ldots, X_n])$ as contained in $H(K[X_i]_{i \geq 1})$.

One should note that f_1 is none other than the augmentation of $K[X]$.

1.5. Embed $K[X_1, \ldots, X_n]$ in $K[T_1, \ldots, T_n]$ by sending X_i to the i-th elementary symmetric function in the T_j. Let the symmetric group Sym_n act by permutation of the T_j. Using the theorem on symmetric polynomials and (1.3.ii), one sees that the induced homomorphism

$$H(K[X_1, \ldots, X_n]) \longrightarrow H(K[T_1, \ldots, T_n])$$

is injective, which again permits us to identify the former with a subgroup of the latter:

$$H(K[X_1, \ldots, X_n]) \simeq H(K[T_1, \ldots, T_n])^{\mathrm{Sym}_n} \subset H(K[T_1, \ldots, T_n]).$$

Let

$$u_i^n : K[X] \longrightarrow K[T_1, \ldots, T_n]$$

be the homomorphism defined by $u_i^n(X) = T_i$, and put

$$u_H^n = \sum_{i=1}^{n} H(u_i^n) : H(K[X]) \longrightarrow H(K[T_1, \ldots, T_n]).$$

The symmetric group permutes the morphisms $H(u_i^n)$, and so leaves u_H^n invariant; thus u_H^n takes its values in

$$H(K[T_1, \ldots, T_n])^{\mathrm{Sym}_n} \simeq H(K[X_1, \ldots, X_n])$$

by (1.3.ii). Notice, finally, that if $H = \widehat{G}$, then

$$u_H^n(1 + Xt) = \prod_{i=1}^{n} (1 + T_i t) = 1 + X_1 t + \cdots + X_n t^n.$$

Theorem 1.6. The map from $\mathrm{Hom}_{\mathrm{Ab\,fil}}(\widehat{G}, H)$ to $H(K[X])$ which, to a morphism of functors, associates its value on the element $1 + Xt$ of $\widehat{G}(K[X])$, is injective. Its image is the subgroup of $H(K[X])$ formed by the elements θ such that, with the notation of 1.4 for the f_n,

i) $H(f_1)(\theta) = 0$,

ii) $\forall n > 1, \quad H(f_n)(u_H^n(\theta)) \equiv u_H^n(\theta) \pmod{F^n H(K[X_1, \ldots, X_n])}$.

First prove injectivity. By Lemma 1.2 it is enough to see that a morphism of functors ξ which is zero on $1 + Xt$ is zero on

$$\varphi = 1 + X_1 t + \cdots + X_n t^n + \cdots .$$

The commutative diagram

$$\begin{array}{ccc} \widehat{G}(K[X]) & \xrightarrow{u^n_{\widehat{G}}} & \widehat{G}(K[X_1, \ldots, X_n]) \\ \xi \big\downarrow & & \big\downarrow \xi \\ H(K[X]) & \xrightarrow[u_H^n]{} & H(K[X_1, \ldots, X_n]) \end{array} \tag{1.6.1}$$

shows that, for every n,

$$\xi(1 + X_1 t + \cdots + X_n t^n) = 0.$$

But

$$\varphi \equiv 1 + X_1 t + \cdots + X_n t^n \pmod{F^{n+1}\widehat{G}},$$

hence

$$\xi(\varphi) \equiv \xi(1 + X_1 t + \cdots + X_n t^n) \pmod{F^{n+1}H};$$

therefore $\xi(\varphi) \equiv 0 \pmod{F^{n+1}H}$ for every n. Since $H(K[X_i]_{i\geq 1})$ is separated and complete, $\xi(\varphi) = 0$.

Now let ξ be any element of $\mathrm{Hom}(\widehat{G}, H)$, and set

$$\theta = \xi(1 + Xt).$$

We show that θ satisfies conditions i) and ii). First,

$$H(f_1)(\theta) = H(f_1)\xi(1 + Xt) = \xi\, \widehat{G}(f_1)(1 + Xt) = \xi(1) = 0.$$

Second,

$$u_H^n(\theta) = \xi(1 + \cdots + X_n t^n)$$

by (1.6.1), while

$$1 + \cdots + X_n t^n \equiv 1 + \cdots + X_{n-1} t^{\,n-1} \pmod{F^n \widehat{G}},$$

and

$$1 + \cdots + X_{n-1} t^{\,n-1} = \widehat{G}(f_n)(1 + \cdots + X_n t^n).$$

Since $H \circ \widehat{G}(f_n) = H(f_n) \circ \xi$, and since ξ is a morphism of filtered functors, condition ii) follows.

It remains to show that if $\theta \in H(K[X])$ satisfies i) and ii), then there exists $\xi \in \mathrm{Hom}(\widehat{G}, H)$ with

$$\theta = \xi(1 + Xt).$$

First determine the value of ξ on the element $1 + \cdots + X_n t^n$ of $\widehat{G}(K[X_1, \ldots, X_n])$. In view of (1.6.1), it must be, by definition,

$$\xi(1 + \cdots + X_n t^n) = \sum_{i=1}^{n} \xi(1 + T_i t),$$

where the $\xi(1 + T_i t)$ are known by functoriality from the morphisms u_i^n.

One then glues the $\xi(1 + \cdots + X_n t^n)$, for variable n, by means of the commutative diagram

$$\begin{array}{ccc} K[X_1, \ldots, X_n] & \xrightarrow{f_n} & K[X_1, \ldots, X_n] \\ {\scriptstyle \sigma_n}\downarrow & & \downarrow{\scriptstyle \sigma'_n} \\ K[T_1, \ldots, T_n] & \xrightarrow[f'_n]{} & K[T_1, \ldots, T_n], \end{array} \tag{1.6.2}$$

where f'_n is determined by $f'_n(T_i) = T_i$ if $i < n$, and $f'_n(T_n) = 0$; where σ_n sends X_i to the i-th elementary symmetric function in $T_1, \ldots, T_n$; and where σ'_n sends X_i to the i-th elementary symmetric function in $T_1, \ldots, T_{n-1}$ for $i < n$, and sends X_n to 0.

Indeed one obtains from this

$$\begin{aligned} H(f_n)(\xi(1 + \cdots + X_n t^n)) &= H(f'_n)\left(\sum_{i=1}^{n} \xi(1 + T_i t)\right) \\ &= \sum_{i=1}^{n-1} \xi(1 + T_i t) = \xi(1 + \cdots + X_{n-1} t^{\,n-1}), \end{aligned}$$

inside $H(K[T_1,\dots,T_{n-1}])$ by the identifications of 1.4. By 1.6.ii the elements $\xi(1+\cdots+X_nt^n)$ define an element ψ of $H(K[X_i]_{i\geq 1})$, since this is a separated complete group. Put

$$\xi(\varphi)=\psi.$$

Finally, if $A\in \mathrm{Ob}(\mathcal{C})$ and $x\in \widehat{G}(A)$, define

$$\xi_A(x)=H(f_x)(\psi),$$

where $f_x : K[X_i]_{i\geq 1}\to A$ is the homomorphism defined in 1.2. Since ξ has already been defined on the elements $1+\cdots+X_nt^n=\varphi_n$, one must verify that the two definitions give the same result, i.e.

$$H(f_{\varphi_n})(\psi)=\xi(1+\cdots+X_nt^n).$$

But for every p one has

$$\psi\equiv \xi(1+\cdots+X_pt^p)\pmod{F^{p+1}H(K[X_i]_{i\geq 1})}.$$

Thus, for $p\geq n$,

$$H(f_{\varphi_n})(\psi)\equiv H(f_{\varphi_n})(\xi(1+\cdots+X_pt^p))\pmod{F^{p+1}H(K[X_i]_{i\geq 1})}.$$

Using the identifications of 1.4 and the gluing of the $\xi(\varphi_m)$ for variable m, one obtains

$$H(f_{\varphi_n})(\xi(\varphi_p))=\xi(\varphi_n).$$

Hence finally

$$\forall p\geq n,\quad H(f_{\varphi_n})(\psi)\equiv \xi(1+\cdots+X_nt^n)\pmod{F^pH(K[X_1,\dots,X_n])}.$$

Since H is separated, the required equality follows.

We have thus defined a system of maps

$$\xi_A : \widehat{G}(A)\longrightarrow H(A).$$

To verify that they constitute a morphism of functors with values in groups, one must prove first that, for every morphism $h : A\to A'$, the square

$$\begin{array}{ccc}\widehat{G}(A) & \xrightarrow{\widehat{G}(h)} & \widehat{G}(A')\\ {\scriptstyle\xi_A}\downarrow & & \downarrow{\scriptstyle\xi_{A'}}\\ H(A) & \xrightarrow[H(h)]{} & H(A')\end{array}$$

is commutative. If $x\in\widehat{G}(A)$, then $h\circ f_x=f_{\widehat{G}(h)(x)}$, whence

$$H(h)(\xi_A(x))=H(h)H(f_x)(\psi)=H(f_{\widehat{G}(h)(x)})(\psi)=\xi_{A'}(\widehat{G}(h)(x)).$$

It remains only to show that the morphism of functors so constructed is compatible with the structures of filtered groups.

Suppose $x\in F^n\widehat{G}(A)$. To say that x is of filtration $>n$ is to say that $f_x : K[X_i]_{i\geq 1}\to A$ factors through the endomorphism g_n of $K[X_i]_{i\geq 1}$ defined by

$$g_n(X_i)=0\quad(1\leq i\leq n-1),\qquad g_n(X_i)=X_i\quad(i\geq n).$$

To show that ξ is compatible with filtrations, it is enough to show that

$$H(g_n)(\xi(\varphi)) \in F^n H.$$

But by construction

$$\xi(\varphi) \equiv \xi(1 + \cdots + X_{n-1}t^{n-1}) \pmod{F^n H}.$$

Therefore

$$H(g_n)(\xi(\varphi)) = H(g_n)(\xi(1 + \cdots + X_{n-1}t^{n-1})) \equiv 0 \pmod{F^n H}.$$

To verify the additivity of ξ, it suffices to do this for the elements of finite degree of $\widehat{G}(A)$, and then pass to the limit. Let X_1, X_2 be two elements of degree n of $\widehat{G}(A)$, and let X be their product. Consider the commutative diagram

$$\begin{array}{ccc} K[X_1, \ldots, X_{2n}] & \xrightarrow{f_X} & A \\ \downarrow & \nearrow_{f'_X} & \\ (K[T_1, \ldots, T_{2n}])^{\mathrm{Sym}_n \times \mathrm{Sym}_n} & & \end{array}$$

where the first factor of $\mathrm{Sym}_n \times \mathrm{Sym}_n$ permutes $T_1, \ldots, T_n$ and the second permutes $T_{n+1}, \ldots, T_{2n}$. The ring $K[X_1, \ldots, X_{2n}]$ is embedded into the ring of invariants by sending X_j to the j-th elementary symmetric function of the T_i; f' sends the i-th elementary symmetric function of $T_1, \ldots, T_n$, respectively of $T_{n+1}, \ldots, T_{2n}$, to the i-th coefficient of X_1, respectively X_2. Then

$$\xi(X) = H(f'_X)\left(\xi\left(\prod_{i=1}^{2n}(1 + T_i t)\right)\right),$$
$$\xi(X_1) = H(f'_X)\left(\xi\left(\prod_{i=1}^{n}(1 + T_i t)\right)\right),$$

and similarly for X_2, using $i = n+1, \ldots, 2n$. Since $H(f'_X)$ is a homomorphism of groups, we are reduced to the case

$$X = \prod_{i=1}^{2n}(1 + T_i t),$$

and in this case the additivity of ξ follows from the definition of the $\xi(1 + X_1 t + \cdots + X_k t^k)$.

1.7. One can generalize the preceding considerations to the case of a product of functors $\widehat{G}$. The functor $(\widehat{G})^k$ is representable by the ring

$$K[X_i^{(j)}]_{j=1,\ldots,k;\ i\geq 1},$$

where $X_i^{(j)}$ has weight i. We denote by $\varphi^{(j)}$ the series

$$1 + X_1^{(j)} t + \cdots + X_n^{(j)} t^n + \cdots .$$

The element $(\varphi^{(j)})_j$ of

$$\left(\widehat{G}(K[X_i^{(j)}])\right)^k$$

has the universal property analogous to that of φ (cf. 1.2).

One can introduce the morphisms $f_n^{(j)}$ and $u_H^{n,(j)}$ as above, by repeating the construction for each family $(X_i^{(j)})_{i\geq 1}$ separately. One obtains a result analogous to Theorem 1.6 by considering

morphisms of functors from $(\widehat{G})^k$ to H which are $\mathbb{Z}$-multilinear and compatible with the filtrations in each of the k arguments separately. They are determined by their value on

$$(1 + X^{(j)}t)_{j=1,\dots,k} \in \big(\widehat{G}(K[X^{(j)}]_j)\big)^k.$$

An element

$$\theta \in H(K[X^{(j)}]_j)$$

determines such a morphism of functors if and only if it satisfies

$$\begin{aligned} &\text{i)} \quad \forall j, \quad H(f_1^{(j)})(\theta) = 0, \\ &\text{ii)} \quad \forall n, j, \quad H(f_n^{(j)})(u_H^{n,(j)}(\theta)) \equiv u_H^{n,(j)}(\theta) \pmod{F^n H}. \end{aligned}$$

The reader will easily convince himself that, apart from notational complications, it is enough to copy the proof of 1.6.

1.8. Let $\mathcal{C}_0$ be the category of K-algebras, and let

$$i : \mathcal{C}_0 \longrightarrow \mathcal{C}$$

be the functor which assigns to a K-algebra A the K-algebra A endowed with the gross filtration. Let

$$g : \mathcal{C} \longrightarrow \mathcal{C}_0$$

be the forgetful functor which forgets the filtration. These functors satisfy the following relations:

$$g \circ i = \mathrm{Id}_{\mathcal{C}_0}, \qquad \widehat{G} \circ i \circ g = \widehat{G}_g, \qquad \widehat{G}_g \circ i \circ g = \widehat{G}_g$$

(cf. 1.3, example 2).

Lemma 1.9. Let $H : \mathcal{C}_0 \to \mathrm{Ab\,fil}$ be a functor on $\mathcal{C}_0$. Then the canonical homomorphism

$$\mathrm{Hom}_{\mathrm{Ab\,fil}}(\widehat{G}, H \circ g) \longrightarrow \mathrm{Hom}_{\mathrm{Ab\,fil}}(\widehat{G} \circ i, H)$$

is an isomorphism.

To see that it is injective, one uses the sequence of canonical homomorphisms

$$\mathrm{Hom}(\widehat{G}, H \circ g) \to \mathrm{Hom}(\widehat{G} \circ i, H) \to \mathrm{Hom}(\widehat{G}_g, H \circ g) \to \mathrm{Hom}(\widehat{G}, H \circ g),$$

the last arrow coming from the fact that $\widehat{G}$ is a subfunctor of $\widehat{G}_g$. To verify that the composite is the identity, observe that a morphism of functors

$$\xi : \widehat{G} \longrightarrow H \circ g$$

is determined by its values on objects of $\mathcal{C}$ whose filtration is gross. Indeed, if $A \in \mathrm{Ob}(\mathcal{C})$, and if A_g is A endowed with the gross filtration, the canonical morphism $A \to A_g$ defines a commutative diagram

$$\begin{array}{ccc} \widehat{G}(A) & \xrightarrow{\xi_A} & (H \circ g)(A) \\ \downarrow & & \downarrow \\ \widehat{G}(A_g) & \xrightarrow[\xi_{A_g}]{} & (H \circ g)(A_g), \end{array}$$

which shows that ξ_A is the restriction of ξ_{A_g} to $\widehat{G}(A)$.

Next consider the composite homomorphism

$$\mathrm{Hom}(\widehat{G} \circ i, H) \longrightarrow \mathrm{Hom}(\widehat{G}_g, H \circ g) \longrightarrow \mathrm{Hom}(\widehat{G}, H \circ g) \longrightarrow \mathrm{Hom}(\widehat{G} \circ i, H).$$

It is clear that this is the identity, whence the asserted result.

Theorem 1.10. Let H be a functor on the category $\mathcal{C}_0$ of K-algebras, with values in the category of separated complete filtered abelian groups, and commuting with invariants under a finite group. Then the map from

$$\mathrm{Hom}_{\mathrm{Ab\,fil}}(\widehat{G} \circ i, H)$$

to $H(K[X])$ which, to a morphism of functors, associates its value on the element $1 + Xt$ of $\widehat{G} \circ i(K[X])$, is injective. Its image is the subgroup of $H(K[X])$ formed by the elements θ such that, with notation analogous to that of 1.4 and 1.5,

i) $H(f_1)(\theta) = 0$,

ii) $\forall n > 1, \quad H(f_n)(u_H^n(\theta)) \equiv u_H^n(\theta) \pmod{F^n H(K[X_1, \ldots, X_n])}$.

The theorem follows immediately from Theorem 1.6 and Lemma 1.9, since $H \circ g(K[X])$ does not depend on the chosen filtration on $K[X]$.

The analogous theorem obtained by replacing $\widehat{G}$ by $(\widehat{G})^k$ is also true (cf. 1.7).

When there is no risk of confusion, we write the functor $\widehat{G} \circ i$ simply as $\widehat{G}$. This is legitimate because i identifies $\mathcal{C}_0$ with a subcategory of $\mathcal{C}$.

1.11. Let $\mathcal{C}_g$ denote the category of graded K-algebras, and let

$$j : \mathcal{C}_g \longrightarrow \mathcal{C}$$

be the functor which assigns to a graded K-algebra B the K-algebra B endowed with the filtration canonically defined by its grading. The associated graded functor

$$\mathrm{Gr} : \mathcal{C} \longrightarrow \mathcal{C}_g$$

will be denoted Gr. There is an isomorphism of functors

$$\varepsilon : \mathrm{Id}_{\mathcal{C}_g} \xrightarrow{\sim} \mathrm{Gr} \circ j.$$

If $B \in \mathrm{Ob}(\mathcal{C}_g)$, denote by

$$1 + \widehat{B}^+$$

the multiplicative group of elements of

$$\prod_{i=0}^{\infty} B^i$$

having augmentation 1. With the filtration analogous to that on $\widehat{G}$, one obtains a functor

$$\mathcal{C}_g \longrightarrow \mathrm{Ab\,fil}.$$

Furthermore, for every $A \in \mathrm{Ob}(\mathcal{C})$, one defines a homomorphism of filtered groups

$$\widehat{G}(A) \longrightarrow 1 + \widehat{\mathrm{Gr}\, A}^+$$

by sending the series $1 + \cdots + a_n t^n + \cdots$ to the series $1 + \cdots + \bar{a}_n + \cdots$, where $\bar{a}_n$ is the class of a_n in $\mathrm{Gr}^n A$. Its kernel is the group $\widehat{G}'(A)$ of formal series such that

$$a_0 = 1, \qquad \forall i \geq 1, \quad a_i \in \mathrm{Fil}^{i+1} A.$$

Thus one has a functorial isomorphism in A:

$$\widehat{G}(A)/\widehat{G}'(A) \xrightarrow{\sim} 1 + \widehat{\mathrm{Gr}\, A}^+.$$

Lemma 1.12. Let $H : \mathcal{C}_g \to \mathrm{Ab\,fil}$ be a functor on $\mathcal{C}_g$. Then the canonical homomorphism

$$\rho : \mathrm{Hom}_{\mathrm{Ab\,fil}}(1 + \hat{\cdot}^+, H) \longrightarrow \mathrm{Hom}_{\mathrm{Ab\,fil}}(\widehat{G}, H \circ \mathrm{Gr})$$

is an isomorphism.

The homomorphism ρ is defined as the composite

$$\mathrm{Hom}(1 + \hat{\cdot}^+, H) \longrightarrow \mathrm{Hom}(1 + \widehat{\mathrm{Gr}(\cdot)}^+, H \circ \mathrm{Gr}) \longrightarrow \mathrm{Hom}(\widehat{G}, H \circ \mathrm{Gr}),$$

the last arrow being defined by the homomorphism

$$\widehat{G} \longrightarrow 1 + \widehat{\mathrm{Gr}(\cdot)}^+.$$

We construct an inverse morphism

$$\rho' : \mathrm{Hom}(\widehat{G}, H \circ \mathrm{Gr}) \longrightarrow \mathrm{Hom}(1 + \hat{\cdot}^+, H).$$

For this, we show that every morphism of functors from $\widehat{G}$ to $H \circ \mathrm{Gr}$ factors through the canonical morphism

$$\widehat{G} \longrightarrow 1 + \widehat{\mathrm{Gr}(\cdot)}^+.$$

Equivalently, it suffices to show that it vanishes on $\widehat{G}'$, by 1.11. Let $A \in \mathrm{Ob}(\mathcal{C})$ and let $x \in \widehat{G}'(A)$. Define a homomorphism of filtered K-algebras

$$K[X_i]_{i \geq 1} \longrightarrow A$$

by sending X_1 to 0 and X_i to the $(i-1)$-st coefficient of x for $i > 1$. Using this homomorphism, it is enough to verify that the morphism of functors considered vanishes on the element

$$1 + X_2 t + \cdots + X_{n+1} t^n + \cdots .$$

Use the endomorphism f of $K[X_i]_{i \geq 1}$ defined by

$$f(X_i) = X_{i+1} \quad \text{for all } i,$$

and the commutative diagram

$$\begin{array}{ccc} \widehat{G}(K[X_i]) & \longrightarrow & (H \circ \mathrm{Gr})(K[X_i]) \\ {\scriptstyle \widehat{G}(f)}\downarrow & & \downarrow{\scriptstyle H(\mathrm{Gr}(f))} \\ \widehat{G}(K[X_i]) & \longrightarrow & (H \circ \mathrm{Gr})(K[X_i]). \end{array}$$

Now $\mathrm{Gr}(f) = \mathrm{Gr}(f_1)$, where f_1 is the augmentation homomorphism of $K[X_i]_{i \geq 1}$. Since the latter annihilates φ, the analogous diagram written for f_1 shows that $H(\mathrm{Gr}(f))$ annihilates the image of φ in $H \circ \mathrm{Gr}(K[X_i]_{i \geq 1})$, and the result follows.

Passing to the quotient, one associates to every morphism of functors

$$\widehat{G} \longrightarrow H \circ \mathrm{Gr}$$

a morphism of functors

$$1 + \widehat{\mathrm{Gr}}^+ \longrightarrow H \circ \mathrm{Gr}\,.$$

By composing with j and using the isomorphism ε, one obtains a morphism

$$1 + \hat{\cdot}^+ \longrightarrow H,$$

which defines the desired homomorphism ρ'. It is immediate to verify that ρ and ρ' are inverses of one another.

Theorem 1.13. Let H be a functor on $\mathcal{C}_g$, with values in the category of separated complete filtered abelian groups, and commuting with invariants under a finite group. Then the map from

$$\mathrm{Hom}_{\mathrm{Ab\,fil}}(1+\hat{\cdot}^+, H)$$

to $H(K[X])$, which to a morphism of functors associates its value on the element $1+X$ of $1+\widehat{K[X]}^+$, is injective. Its image is the subgroup of $H(K[X])$ formed by the elements θ such that, with notation as in 1.4 and 1.5,

i) $H(f_1)(\theta) = 0$,

ii) $\forall n > 1, \quad H(f_n)(u_H^n(\theta)) \equiv u_H^n(\theta) \pmod{F^n H(K[X_1, \ldots, X_n])}$.

This is immediate from 1.6 and 1.12. There is an analogous statement replacing $\widehat{G}$ by $(\widehat{G})^k$.

Remark 1.14. If H is a functor on $\mathcal{C}_g$, with values in abelian groups, commuting with invariants under a finite group, and satisfying the condition

$$\forall B \in \mathrm{Ob}(\mathcal{C}_g), \qquad H(B) \simeq \varprojlim_n H(B/B^{\geq n}), \qquad B^{\geq n} = \prod_{i \geq n} B^i,$$

then condition ii) of 1.13 is always satisfied if one takes for the filtration on H the filtration by the kernels of

$$H(B) \longrightarrow H(B/B^{\geq n}),$$

which is separated and complete. Indeed, if p_n is the canonical homomorphism

$$K[X_1, \ldots, X_n] \longrightarrow K[X_1, \ldots, X_n]/K[X_1, \ldots, X_n]^{\geq n},$$

then

$$p_n \circ f_n = p_n,$$

and hence

$$H(p_n)[H(f_n) \circ u_H^n(\theta) - u_H^n(\theta)] = 0.$$

This says precisely that

$$H(f_n) \circ u_H^n(\theta) - u_H^n(\theta) \in F^n H(K[X_1, \ldots, X_n]).$$

Thus, in order to give a morphism of functors from $1+\hat{\cdot}^+$ to H, it is enough to give an element of $H(K[X])$ satisfying only condition i) of 1.13.

1.15. Let $H : \mathcal{C} \to \mathrm{Ab\,fil}$ (respectively $\mathcal{C}_0 \to \mathrm{Ab\,fil}$, $\mathcal{C}_g \to \mathrm{Ab\,fil}$) be a functor satisfying the conditions of 1.3 (respectively 1.10, 1.13), and let

$$\xi : (\widehat{G})^k \to H$$

(respectively $(\widehat{G} \circ i)^k \to H$, $(1+\hat{\cdot}^+)^k \to H$) be a morphism of functors. We have seen in 1.7 that ξ is determined by its value on the element

$$(\varphi^{(j)})_{j=1,\ldots,k}$$

of

$$\left(\widehat{G}(K[X_i^{(j)}]_{j=1,\ldots,k;\ i\geq 1})\right)^k$$

(respectively similarly). Suppose H is one of the functors

$$\widehat{G}, \quad \widehat{G}_g, \quad \widehat{G}_a, \quad 1+\widehat{\mathrm{Gr}}^+, \quad \text{etc.}$$

Then the element $\xi((\varphi^{(j)}))$ is a formal series with coefficients in

$$K[X_i^{(j)}]_{i\geq 1,\ j=1,\ldots,k}.$$

The n-th coefficient of this series is called the n-th universal polynomial of ξ. The knowledge of these polynomials is equivalent to the knowledge of ξ.

According to the proof of 1.6, these polynomials are themselves determined by the element

$$\xi(1+X^{(1)}t,\ldots,1+X^{(k)}t).$$

The calculation is performed by the method of the proof: one computes the elements

$$\xi(1+X_1^{(1)}t+\cdots+X_n^{(1)}t^n,\ldots,1+X_1^{(k)}t+\cdots+X_n^{(k)}t^n),$$

by decomposing

$$1+X_1^{(1)}t+\cdots+X_n^{(1)}t^n=\prod_{j=1}^{n}(1+T_j^{(1)}t)$$

and by using the additivity of ξ. The polynomials thus obtained are symmetric with respect to the $T_j^{(i)}$, for fixed i and variable j, and can be expressed as functions of the $X_j^{(i)}$. Gluing by means of the filtration of H, one thus determines the universal polynomials of ξ. If

$$(\psi^{(1)},\ldots,\psi^{(k)})\in(\widehat{G}(A))^k,$$

the calculation of $\xi(\psi^{(1)},\ldots,\psi^{(k)})$ is made by substituting the coefficients of the $\psi^{(i)}$ for the $X_j^{(i)}$ in the universal polynomials.

Suppose that there exists an integer m such that the coefficient of t^n in

$$\theta=\xi(1+X^{(1)}t,\ldots,1+X^{(k)}t)$$

is a polynomial whose isobaric components have weights between n and m. Then the k-th universal polynomial of ξ has isobaric components whose weights range between k and km. This follows immediately from the calculation just described and from the theorem on symmetric functions.

In particular, if $H=\widehat{G}$, then the n-th universal polynomial of ξ has no component of weight $<n$. Now consider the canonical morphism

$$H\longrightarrow 1+\widehat{\mathrm{Gr}}^+.$$

Composing it with ξ gives a morphism

$$(\widehat{G})^k\longrightarrow 1+\widehat{\mathrm{Gr}}^+,$$

which, by the proof of 1.12, factors through

$$(1+\widehat{\mathrm{Gr}}^+)^k$$

and defines a morphism

$$\bar{\xi}:(1+\hat{\cdot}^+)^k\longrightarrow 1+\hat{\cdot}^+.$$

One sees at once that the n-th universal polynomial of $\bar{\xi}$ is the same as that of

$$(\widehat{G})^k \longrightarrow 1 + \widehat{\mathrm{Gr}}^+,$$

that is, the isobaric component of weight n of the n-th universal polynomial of ξ.

The same remarks apply to the case $H = \widehat{G}_a$. Then one may define a morphism of functors

$$H \longrightarrow \widehat{\mathrm{Gr}}^+$$

analogously to 1.11, by putting

$$\widehat{B}^+ = \prod_{i \geq 1} B^i$$

for a graded algebra B; one repeats the same reasoning and reaches the conclusions of the preceding paragraph.

1.16. We finish with an example. Suppose $K = \mathbb{Q}$. Define an endomorphism of the functor $1 + \hat{\cdot}^+$, denoted Todd and called the Todd character, by putting

$$\mathrm{Todd}(1 + X) = \frac{X}{1 - e^{-X}}.$$

The conditions i) and ii) of Theorem 1.13 are immediately verified, which shows that an endomorphism of $1 + \hat{\cdot}^+$ has indeed been defined.

2. Definition of λ-rings; examples

In this paragraph the base ring of paragraph 1 will be $\mathbb{Z}$, except in 2.9. We place ourselves in the category $\mathcal{C}_0$ of 1.8, and write $\widehat{G}$ for the restriction of $\widehat{G}$ to $\mathcal{C}_0$, as in 1.10.

Definition 2.1. A *pre-λ-ring* is a commutative ring K with unit, endowed with a homomorphism of abelian groups

$$\lambda_t : K \longrightarrow 1 + K[[t]]^+$$

such that, for every $x \in K$,

$$\lambda_t(x) = 1 + xt + \cdots .$$

We shall write

$$\lambda_t(x) = \sum_{i \geq 0} \lambda^i(x) t^i.$$

Thus giving a pre-λ-ring structure on a ring K is equivalent to giving a family of maps

$$\lambda^i : K \longrightarrow K \qquad (i \in \mathbb{N})$$

such that

i) $\forall x \in K, \quad \lambda^0(x) = 1,$

ii) $\forall x \in K, \quad \lambda^1(x) = x,$

iii) $\forall x, y \in K, \ \forall n \in \mathbb{N}, \quad \lambda^n(x+y) = \sum_{p+q=n} \lambda^p(x)\lambda^q(y).$

If K, K' are two pre-λ-rings and $f : K \to K'$ is a ring homomorphism, we say that f is a homomorphism of pre-λ-rings, or a λ-homomorphism, if the diagram

$$\begin{array}{ccc} K & \xrightarrow{\lambda_t} & 1 + K[[t]]^+ \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle \widehat{G}(f)} \\ K' & \xrightarrow[\lambda_t]{} & 1 + K'[[t]]^+ \end{array}$$

is commutative. This is equivalent to the relations

$$\forall x \in K,\ \forall i \in \mathbb{N}, \qquad \lambda^i(f(x)) = f(\lambda^i(x)).$$

Examples 2.2.

a) One can give all pre-λ-ring structures on $\mathbb{Z}$. It is enough to give $\lambda_t(1)$, which is then a formal series with integral coefficients subject to the sole condition that it begin with $1 + t$.

b) Let (T, A) be a commutatively ringed topos, and let K be the "Grothendieck group" of A-modules locally isomorphic to a direct factor of a free A-module of finite type. We know that K can be given a ring structure by the tensor product (Exposé IV), and we now endow it with a pre-λ-ring structure as follows. For every A-module E locally a direct factor of a free module of finite type, let $\lambda^i(E)$ denote the class in K of the i-th exterior power of E, which is again locally a direct factor of a free module of finite type. This defines a function from the category of such A-modules to the abelian group $1 + K[[t]]^+$. It remains to show that this function is additive, which will imply that it factors through K and hence gives the desired structure.

Lemma 2.2.1. Let

$$0 \longrightarrow E' \xrightarrow{u} E \xrightarrow{v} E'' \longrightarrow 0$$

be an exact sequence of A-modules which is locally split, for example with E'' locally a direct factor of a free module of finite type. There exists on $\Lambda^n(E)$ a finite filtration and isomorphisms

$$\Lambda^{n-p}(E') \otimes_A \Lambda^p(E'') \xrightarrow{\sim} \mathrm{Gr}^p\, \Lambda^n(E).$$

Take for $F^p\Lambda^n(E)$ the image of the canonical morphism

$$\Lambda^{n-p}(E') \otimes_A \Lambda^p(E) \longrightarrow \Lambda^n(E) \quad (0 \le p \le n).$$

If $p > n$, put $F^p\Lambda^n(E) = \Lambda^n(E)$, and if $p < 0$, put $F^p\Lambda^n(E) = 0$. This does indeed define a finite filtration on $\Lambda^n(E)$.

Define a homomorphism

$$f_p : \Lambda^{n-p}(E') \otimes_A \Lambda^p(E'') \longrightarrow F^p\Lambda^n(E)/F^{p-1}\Lambda^n(E)$$

by

$$f_p(x'_1 \wedge \cdots \wedge x'_{n-p} \otimes x''_1 \wedge \cdots \wedge x''_p) = \mathrm{cl}\big(u(x'_1) \wedge \cdots \wedge u(x'_{n-p}) \wedge x_1 \wedge \cdots \wedge x_p\big),$$

where the x_i are lifts in E of the x''_i in E''. This visibly does not depend on the choice of the x_i. If the exact sequence is locally split, then f_p is an isomorphism, since locally

$$\Lambda^n(E) \simeq \bigoplus_{p+q=n} \Lambda^p(E') \otimes_A \Lambda^q(E'').$$

When E', E, E'' are locally direct factors of free modules of finite type, the $\mathrm{Gr}^p\, \Lambda^n(E)$ are locally direct factors of free modules of finite type, and hence so are the $F^p\Lambda^n(E)$. Thus one may write in K

$$\lambda^n(E) = \sum_{p=0}^{n} \mathrm{cl}(\mathrm{Gr}^p\, \Lambda^n(E)) = \sum_{p=0}^{n} \lambda^{n-p}(E')\lambda^p(E''),$$

which gives the required additivity.

Let (T, A) and (T', A') be two commutatively ringed topoi, and let

$$f : (T, A) \longrightarrow (T', A')$$

be a morphism of ringed topoi. We know (Exposé IV, 2.7) that f defines a morphism of rings on the corresponding K's, namely

$$f^* : K^*_{\text{naif}}(T', A') \longrightarrow K^*_{\text{naif}}(T, A).$$

Since inverse image commutes with exterior powers, the corresponding morphism f^* on K is a λ-homomorphism for the structure just defined.

We point out two special cases:

- If X is a scheme, then $K^*_{\text{naif}}(X)$ is thus endowed with a pre-λ-ring structure. This is the case which will be used later in the Seminar, and it may be regarded as the model for the general theory of λ-rings.
- If A is a ring, $X = \operatorname{Spec} A$, and G is a group acting trivially on A, then, taking for (T, A) the topos of sheaves of sets on X on which G acts, the ring K thus obtained is the representation ring of G in the projective A-modules of finite type.

2.3. Let K be a commutative ring with unit. We propose to endow the abelian group

$$\widehat{G}(K) = 1 + K[[t]]^+$$

with a pre-λ-ring structure, functorially in K. To this end, we apply the results of 1.10 to the functor $\widehat{G}$.

First define multiplication by giving a $\mathbb{Z}$-bilinear morphism of functors

$$\widehat{G} \times \widehat{G} \longrightarrow \widehat{G}$$

through the element $1 + XYt$ of $\widehat{G}(\mathbb{Z}[X, Y])$. This element satisfies 1.7.i; to see that it satisfies 1.7.ii, one must show that in

$$\prod_{i=1}^{n} (1 + T_i Y t),$$

when expressed by means of the elementary symmetric functions X_j in the T_i, the variable X_n does not occur in the coefficients of t^k for $k < n$. This is evident by degree considerations.

The law so defined will be denoted by the sign $\circ$. Thus, by definition,

$$(1 + Xt) \circ (1 + Yt) = 1 + XYt. \tag{2.3.1}$$

It is distributive by construction, and it is associative and commutative by the diagrams

$$\begin{array}{ccc} \widehat{G} \times \widehat{G} \times \widehat{G} & \to & \widehat{G} \times \widehat{G} \\ \downarrow & & \downarrow \\ \widehat{G} \times \widehat{G} & \longrightarrow & \widehat{G} \end{array} \qquad \begin{array}{ccc} \widehat{G} \times \widehat{G} & \to & \widehat{G} \times \widehat{G} \\ \downarrow & & \downarrow \\ \widehat{G} & \xrightarrow[\text{Id}]{} & \widehat{G}, \end{array}$$

where the meaning of the arrows is evident, and where it is enough to verify commutativity on the elements $1 + Xt, 1 + Yt, 1 + Zt$, respectively $1 + Xt, 1 + Xt$, of $\widehat{G}(\mathbb{Z}[X, Y, Z])$, respectively $\widehat{G}(\mathbb{Z}[X, Y])$, by 1.10; this verification is immediate.

By 1.8, the product under this law of two series is calculated by substituting their coefficients into the universal polynomials of the law. The n-th universal polynomial will be denoted P_n. It is a polynomial in

$$\mathbb{Z}[X_i, Y_j]_{1 \leq i,j \leq n}$$

which is isobaric of weight n with respect to each of the two groups of variables (see 1.15), and symmetric with respect to these two groups. For example,

$$P_2(X_1, X_2; Y_1, Y_2) = X_2 Y_1^2 + Y_2 X_1^2 - 2X_2 Y_2.$$

One also has the following relation: if $K \in \mathrm{Ob}(\mathcal{C}_0)$, $\psi \in \widehat{G}(K)$, and $a \in K$, then

$$\psi(t) \circ (1 + at) = \psi(at). \tag{2.3.2}$$

As usual, by the standard functorial argument this reduces to the case $K = \mathbb{Z}[X, Y]$, $\psi = 1 + Xt$, $a = Y$, where it is nothing other than (2.3.1).

Applying (2.3.2) to $\widehat{G}(K) = 1 + K[[t]]^+$ with $a = 1$, one sees that $1 + t$ is the unit for this multiplication. To avoid confusion, we sometimes denote it by 1, or by $1_\circ$.

The functor $\widehat{G}$ can now be considered as a functor from $\mathcal{C}_0$ to the category of commutative rings with unit, and hence can be composed with itself. To avoid confusion, choose different indeterminates for each of the two factors in the product of $\widehat{G}$ with itself; we indicate the indeterminate by an exponent when necessary:

$$\widehat{G}^t, \quad \widehat{G}^u, \quad \text{etc.}$$

For $A \in \mathrm{Ob}(\mathcal{C}_0)$ one has

$$\widehat{G}^u \circ \widehat{G}^t(A) = 1 + \{1 + A[[t]]^+\}[[u]]^+.$$

To define the operations λ^i on $1 + K[[t]]^+$, we are therefore going to give a morphism of functors

$$\widehat{G} \longrightarrow \widehat{G}^u \circ \widehat{G}^t.$$

For this, one must first define a filtration of the functor $\widehat{G}^u \circ \widehat{G}^t$ which permits the gluing of 1.6.

First note that $F^k \widehat{G}$ is an ideal for the law $\circ$. For this follows, for the product

$$\left(1 + \sum_{i \geq k} X_i t^i\right) \circ (1 + Yt),$$

by reducing by functoriality to the case $A = \mathbb{Z}[X_i, Y]_{i \geq 1}$, and using (2.3.2). Therefore $F^n(\widehat{G}^u \circ \widehat{G}^t)$ is defined to be the set of series of the form

$$1 + \psi_1 u + \cdots + \psi_i u^i + \cdots, \qquad \psi_i \in F^{[n/i]} \widehat{G},$$

where $[n/i]$ denotes the integral part of n/i.

The element defining the morphism λ_u is

$$1 + \{1 + Xt\}u.$$

The reader will verify as an exercise that the conditions of 1.6 are indeed fulfilled; in fact the filtration was chosen ad hoc.

Again, the operations λ^i are calculated by substitution from

$$\lambda_u(1 + \cdots + X_n t^n + \cdots),$$

and so are determined by universal polynomials. Denote by

$$Q_{i,j}(X_1, \ldots, X_{ij})$$

the coefficient of t^j in

$$\lambda^i(1 + \cdots + X_n t^n + \cdots).$$

It is an isobaric polynomial of weight ij with respect to the variables $X_1, \ldots, X_{ij}$ (by a verification analogous to that of 1.15). It is calculated by symmetric functions from the defining element

$$\lambda_u(1 + Xt) = 1 + \{1 + Xt\}u. \tag{2.3.3}$$

For example,

$$Q_{2,2}(X_1, X_2, X_3, X_4) = X_1X_3 - X_4.$$

Finally, we indicate the origin of formulas (2.3.1) and (2.3.3). Consider the example 2.2.b, where the operations λ^i are defined by exterior powers of A-modules. We want

$$\lambda_t : K \longrightarrow \widehat{G}(K)$$

to be a λ-homomorphism. Thus on $\widehat{G}$ one must define laws such that, for all A-modules E, F,

$$\lambda_t(EF) = \lambda_t(E) \circ \lambda_t(F), \qquad \lambda_u(\lambda_t(E)) = \widehat{G}^u_{\lambda_t}(\lambda_t(\lambda_u(E))).$$

The relations (2.3.1) and (2.3.3) are precisely the preceding relations applied to the case where E and F are invertible modules.

We shall see in Exposé VI to what extent the desired property is verified.

Definition 2.4. A pre-λ-ring K will be called a *λ-ring* if the homomorphism of abelian groups

$$\lambda_t : K \longrightarrow 1 + K[[t]]^+$$

is a λ-homomorphism for the pre-λ-ring structure on the second member defined in 2.3. Thus the following relations hold for all $x, y \in K$:

$$\lambda_t(1) = 1 + t, \qquad \lambda_t(xy) = \lambda_t(x) \circ \lambda_t(y), \qquad \lambda_u(\lambda_t(x)) = \widehat{G}(\lambda_t)(\lambda_u(x)). \tag{2.4.1}$$

In terms of the maps λ^i, the last two relations are equivalent, for $x, y \in K$ and $i, j \in \mathbb{N}$, to

$$\lambda^i(xy) = P_i(\lambda^1(x), \ldots, \lambda^i(x); \lambda^1(y), \ldots, \lambda^i(y)), \tag{2.4.2}$$

$$\lambda^j(\lambda^i(x)) = Q_{i,j}(\lambda^1(x), \ldots, \lambda^{ij}(x)). \tag{2.4.3}$$

We note that here we depart from the usual terminology (cf. [1]), where what we call a pre-λ-ring was called a λ-ring, and our λ-rings were called "special" λ-rings. The reason is that only "special" λ-rings are useful in practice.

Examples 2.5.

a) We have determined all pre-λ-ring structures on $\mathbb{Z}$. It follows from (2.4.1) that only the structure defined by

$$\lambda_t(1) = 1 + t$$

is capable of being a λ-ring structure. One then has

$$\lambda_t(n) = (1 + t)^n,$$

hence

$$\forall n, n' \in \mathbb{Z}, \quad \lambda_t(n) \circ \lambda_t(n') = (1+t)^n \circ (1+t)^{n'} = (1+t)^{nn'} = \lambda_t(nn'),$$

and

$$\lambda_u((1+t)^n) = (\lambda_u(1+t))^n = (1+\{1+t\}u)^n = \widehat{G}(\lambda_t)((1+u)^n) = \widehat{G}(\lambda_t)(\lambda_u(n)).$$

Thus this is indeed a λ-ring structure. If $\binom{X}{k}$ denotes the polynomial with rational coefficients

$$\frac{1}{k!}X(X-1)\cdots(X-k+1),$$

then

$$\lambda^i(n) = \binom{n}{i}. \tag{2.5.1}$$

b) For every ring K, the pre-λ-ring $1 + K[[t]]^+$ is a λ-ring. First,

$$\lambda_u(1) = \lambda_u(1+t) = 1 + \{1+t\}u = 1 + 1 \cdot u.$$

The other relations are verified by the commutativity of the diagrams

$$\begin{array}{ccc} \widehat{G}^t \times \widehat{G}^t & \xrightarrow{\lambda_u \times \lambda_u} & (\widehat{G}^u \circ \widehat{G}^t) \times (\widehat{G}^u \circ \widehat{G}^t) \\ {\scriptstyle\circ}\downarrow & & \downarrow{\scriptstyle\circ} \\ \widehat{G}^t & \xrightarrow[\lambda_u]{} & \widehat{G}^u \circ \widehat{G}^t, \end{array} \qquad \begin{array}{ccc} \widehat{G}^t & \xrightarrow{\lambda_v} & \widehat{G}^v \circ \widehat{G}^t \\ {\scriptstyle\lambda_u}\downarrow & & \downarrow{\scriptstyle\widehat{G}^v(\lambda_u)} \\ \widehat{G}^u \circ \widehat{G}^t & \underset{\lambda_v}{\to} & \widehat{G}^v \circ \widehat{G}^u \circ \widehat{G}^t, \end{array}$$

which are checked by 1.10 on the elements $1 + Xt$ and $1 + Yt$. For the first,

$$\begin{aligned} \lambda_u(1+Xt) \circ \lambda_u(1+Yt) &= (1+\{Xt\}u) \circ (1+\{1+Yt\}u) \\ &= 1 + \{(1+Xt) \circ (1+Yt)\}u \\ &= 1 + \{1+XYt\}u \\ &= \lambda_u((1+Xt) \circ (1+Yt)). \end{aligned}$$

For the second,

$$\lambda_v(\lambda_u(1+Xt)) = 1 + \{1 + \{1+Xt\}u\}v = \widehat{G}^v(\lambda_u)\lambda_v(1+Xt).$$

c) The geometric examples of 2.2 will be treated later.

2.6. One can generalize Example 2.5.a as follows. Let K be a commutative ring with unit such that:

i) K is torsion-free,
ii) $\forall x \in K,\ \forall n \in \mathbb{N}, \quad \binom{x}{n} \in K.$

Then, for all $x \in K$ and all $n \in \mathbb{N}$, put

$$\lambda^n(x) = \binom{x}{n},$$

that is,

$$\lambda_t(x) = \sum_{n=0}^{\infty} \binom{x}{n} t^n = (1+t)^x = \exp(x \operatorname{Log}(1+t)), \tag{2.6.1}$$

where the last identity is considered in $K \otimes_{\mathbb{Z}} \mathbb{Q}[[t]]$. By multiplicativity of the exponential, this defines a pre-λ-ring structure on K.

To see that it is a λ-ring structure, one must prove the relations (2.4.2), and it is enough to prove them in $K \otimes \mathbb{Q}$, by i). One is then reduced by functoriality to the case $K = \mathbb{Q}[X, Y]$ and to the elements X, Y. In view of the definition of the λ^i, the two sides of the equalities (2.4.2) are polynomials in X, Y, with rational coefficients. It is therefore enough, in order to prove their equality, to show that they take the same value for all integral values of X, Y. But the relations obtained by substituting integral values in X, Y are precisely those expressing that the pre-λ-ring $\mathbb{Z}$ of 2.5.a is a λ-ring. They are therefore satisfied.

Definition 2.7. A *binomial ring* is a ring satisfying the conditions 2.6.i and ii), endowed with the λ-ring structure defined by (2.6.1).

Example 2.8. Let X be a site, K a binomial ring, and $\mathcal{K}$ the sheaf associated to the constant presheaf with value K on X. Then $H^0(X, \mathcal{K})$ is a binomial ring. Indeed, the conditions 2.6 are preserved under passage to an inductive limit. In particular, $H^0(X, \mathbb{Z})$ is a binomial ring.

2.9. Let K be a binomial ring and A a K-algebra. For every series

$$\varphi \in \widehat{G}(A)$$

and every $a \in K$, one can define a series φ^a in the usual way. Writing $\varphi = 1 + \psi$, put

$$\varphi^a = (1+\psi)^a = \sum_{n=0}^{\infty} \binom{a}{n} \psi^n \, (= \exp(a \operatorname{Log} \varphi)), \tag{2.9.1}$$

where the last equality can be written only modulo torsion. These formulas are obtained by substitution from the analogous formulas for $\varphi = 1 + t$. Therefore the following relations, the classical properties of the exponential, remain valid for $a, b \in K$ and $\varphi, \psi \in \widehat{G}(A)$:

$$\varphi^a \varphi^b = \varphi^{a+b}, \qquad \varphi^{ab} = (\varphi^a)^b, \qquad \varphi^a \psi^a = (\varphi\psi)^a. \tag{2.9.2}$$

Continuation of 2.9

We still suppose that K is binomial. Multiplication, for the law $\circ$, by $\lambda_t(a)$, where $a \in K$, defines a morphism of functors

$$\widehat{G}_K \longrightarrow \widehat{G}_K$$

which is characterized by its value on the element $1 + Xt$ of $G(K[X])$. Thus

$$\lambda_t(a) \circ (1 + Xt) = \lambda_{Xt}(a),$$

and hence

$$\lambda_t(a) \circ (1+Xt) = (1+Xt)^a = \exp(a \operatorname{Log}(1+Xt)) = \sum_{n=0}^{\infty} \binom{a}{n} X^n t^n. \tag{2.9.3}$$

It follows that

$$\lambda_t(a) \circ \varphi = \varphi^a \quad (= \exp(a \operatorname{Log} \varphi)). \tag{2.9.4}$$

Indeed, the two members are additive functors which coincide on $1 + Xt$. From (2.9.3) and 1.15 one obtains that the universal polynomial of degree n defining multiplication by $\lambda_t(a)$ is isobaric of weight n. We denote it by $R_{n,a}$.

Finally, if A is a K-λ-algebra and $b \in A$, then

$$\lambda_t(ab) = (\lambda_t(b))^a. \tag{2.9.5}$$

This follows from $\lambda_t(ab) = \lambda_t(a) \circ \lambda_t(b)$ and from (2.9.4).

3. The operations γ

We still work over the category $\mathscr{C}_0$.

3.1. Let K be a λ-ring. We shall define from the operations λ^i new operations denoted γ^i. They are the operations which are adapted to Chern classes. If E is a vector bundle of rank d, the top Chern class of E is represented, in K-theoretic language, by the alternating sum of the exterior powers. To obtain the n-th class, one first replaces E by $E \oplus \mathbf{1}^{n-d}$, so that the same top-class recipe applies. This motivates the formula below.

Proposition 3.2. Let K be a λ-ring.

i) For every $x \in K$ and every $n \in \mathbb{N}$,

$$\lambda^n(x+n-1) = (-1)^n \sum_{i=0}^{n} (-1)^i \lambda^i(x+n).$$

ii) If

$$\gamma^n(x) = \lambda^n(x+n-1), \qquad \gamma_t(x) = \sum_{n\geq 0} \gamma^n(x) t^n,$$

then

$$\gamma_t(x) = \lambda_{t/(1-t)}(x), \qquad \text{hence} \qquad \lambda_t(x) = \gamma_{t/(1+t)}(x).$$

Thus knowledge of the operations γ is equivalent to knowledge of the operations λ.

Proof. For i),

$$\lambda^n(x+n-1) = \sum_{i=0}^{n} \lambda^i(x+n)\lambda^{n-i}(-1).$$

Since $\lambda_t(1) = 1+t$, one has $\lambda_t(-1) = 1/(1+t)$, and hence $\lambda^k(-1) = (-1)^k$, giving the desired relation. For ii),

$$\lambda_{t/(1-t)}(x) = \sum_{n\geq 0} \lambda^n(x) t^n (1-t)^{-n},$$

and

$$t^n(1-t)^{-n} = \sum_{p\geq n} \binom{p-1}{p-n} t^p.$$

The coefficient of t^p is therefore

$$\sum_{n=0}^{p} \lambda^n(x) \binom{p-1}{p-n} = \sum_{n=0}^{p} \lambda^n(x)\lambda^{p-n}(p-1) = \lambda^p(x+p-1).$$

3.3. If $f : K \to K'$ is a homomorphism of λ-rings, then f is a λ-homomorphism if and only if, for every $i \in \mathbb{N}$,

$$f(\gamma^i(x)) = \gamma^i(f(x)),$$

or equivalently

$$\gamma_t(f(x)) = \widehat{G}(f)(\gamma_t(x)).$$

3.4. From 3.2 one obtains

$$\gamma^0(x) = 1, \qquad \gamma^1(x) = x, \qquad \gamma^n(x+y) = \sum_{p+q=n} \gamma^p(x)\gamma^q(y). \tag{3.4.1}$$

Thus γ_t defines a new pre-λ-ring structure. It is not, in general, a λ-ring structure. Let ρ_t denote the automorphism of the functor $\widehat{G}$ induced by the change of variable

$$t \longmapsto \frac{t}{1-t}.$$

Then $\gamma_t = \rho_t \lambda_t$. Transporting the λ-ring functor structure of $\widehat{G}$ by ρ_t gives a second structure on $\widehat{G}$, for which $\gamma_t : K \to \widehat{G}(K)$ is a λ-homomorphism whenever K is a λ-ring.

3.5. The multiplication in this transported structure is the composite

$$\widehat{G} \times \widehat{G} \xrightarrow{\rho_t^{-1} \times \rho_t^{-1}} \widehat{G} \times \widehat{G} \xrightarrow{\circ} \widehat{G} \xrightarrow{\rho_t} \widehat{G}.$$

It will be denoted ∇. It is determined by

$$\begin{aligned}(1+Xt)\nabla(1+Yt) &= \rho_t\Big(\rho_t^{-1}(1+Xt) \circ \rho_t^{-1}(1+Yt)\Big) \\ &= \rho_t\left(\frac{1+(X+1)t}{1+t} \circ \frac{1+(Y+1)t}{1+t}\right) \\ &= \rho_t\left(\frac{(1+((X+1)(Y+1))t)(1+t)}{(1+(X+1)t)(1+(Y+1)t)}\right) \\ &= \frac{1+(1+X+Y+XY)t}{(1+Xt)(1+Yt)}. \end{aligned} \tag{3.5.1}$$

Thus, for $x, y \in K$,

$$\gamma_t(xy) = \gamma_t(x) \nabla \gamma_t(y). \tag{3.5.2}$$

The universal polynomial of degree n for this law will be denoted P'_n. Its isobaric components have weights between n and $2n$ in each of the two groups of variables, and

$$\gamma^n(xy) = P'_n(\gamma^1(x), \dots, \gamma^n(x), \gamma^1(y), \dots, \gamma^n(y)). \tag{3.5.3}$$

The unit for ∇ is $\gamma_t(1) = 1/(1-t)$.

3.6. The operations λ' of the transported structure are defined by

$$\begin{array}{ccc} & \widehat{G} & \\ 1 + K[[t]]^+ & \xrightarrow{\lambda_u} & 1 + \{1 + K[[t]]^+\}[[u]]^+ \\ {\scriptstyle \rho_t}\downarrow & & \downarrow{\scriptstyle \widehat{G}(\rho_t)} \\ 1 + K[[t]]^+ & \xrightarrow[\lambda'_u]{} & 1 + \{1 + K[[t]]^+\}[[u]]^+. \end{array} \tag{3.6.1}$$

If γ' denotes the γ-operations attached to these operations λ', then

$$\gamma'_u(1+Xt) = \frac{1}{1-u} + \{1+Xt\}u. \tag{3.6.2}$$

Let $Q'_{i,j}$ be the coefficient of t^j in $\gamma'^i(1 + X_1 t + X_2 t^2 + \cdots)$. It is a polynomial in $\mathbb{Z}[X_1, \dots, X_{ij}]$, whose isobaric components have weights from j to ij. For a λ-ring K and $x \in K$,

$$\gamma_t(\lambda^i(x)) = \lambda'^i(\gamma_t(x)), \qquad \gamma_t(\gamma^i(x)) = \gamma'^i(\gamma_t(x)), \tag{3.6.3}$$

and therefore

$$\gamma^j(\gamma^i(x)) = Q'_{i,j}(\gamma^1(x), \dots, \gamma^{ij}(x)). \tag{3.6.4}$$

The transported pre-λ-ring structure on $\widehat{G}$ is itself a λ-ring structure.

3.7. We denote by $\widehat{G}_\circ$ the functor $\widehat{G}$ with the structure of §2, and by $\widehat{G}_\nabla$ the same functor with the structure of §3. Giving a λ-ring structure on a ring A is equivalent either to giving a ring homomorphism $A \to \widehat{G}_\circ(A)$ satisfying the usual diagram for λ_t, or to giving a ring homomorphism $A \to \widehat{G}_\nabla(A)$ satisfying the corresponding diagram for γ_t. Explicitly, the two diagrams are

$$\begin{array}{ccc} A & \xrightarrow{\lambda_u} & \widehat{G}^u_\circ(A) \\ {\scriptstyle\lambda_t}\downarrow & & \downarrow{\scriptstyle\widehat{G}^u_\circ(\lambda_t)} \\ \widehat{G}^t_\circ(A) & \underset{\lambda_u}{\to} & \widehat{G}^u_\circ(\widehat{G}^t_\circ(A)) \end{array} \tag{3.7.1}$$

and

$$\begin{array}{ccc} A & \xrightarrow{\gamma_u} & \widehat{G}^u_\nabla(A) \\ {\scriptstyle\gamma_t}\downarrow & & \downarrow{\scriptstyle\widehat{G}^u_\nabla(\gamma_t)} \\ \widehat{G}^t_\nabla(A) & \underset{\gamma_u}{\to} & \widehat{G}^u_\nabla(\widehat{G}^t_\nabla(A)). \end{array} \tag{3.7.2}$$

3.8. Let K be a binomial ring. From (2.6.1), for $x \in K$,

$$\gamma_t(x) = \left(\frac{1}{1-t}\right)^x = \exp(-x \operatorname{Log}(1-t)). \tag{3.8.1}$$

For $a \in K$, multiplication by $\gamma_t(a)$ for the law ∇ is characterized by its value on $1 + Xt$:

$$\gamma_t(a)\nabla(1+Xt) = (1+Xt)^a = \exp(a \operatorname{Log}(1+Xt)) = \sum_{n=0}^{\infty} \binom{a}{n} X^n t^n. \tag{3.8.2}$$

Thus the universal polynomial of degree n defining this multiplication is again $R_{n,a}$.

Definition 3.9. Let K be a λ-ring. An *augmented K-λ-algebra* is a K-λ-algebra A, together with a λ-homomorphism of K-algebras

$$\epsilon : A \longrightarrow K.$$

Morphisms are λ-homomorphisms compatible with the augmentations.

Example 3.9.1. Let (X, A) be a locally ringed topos. The Grothendieck group $K^\circ(X)$ of locally free finite-type A-modules has a natural pre-λ-ring structure by exterior powers. There is a natural λ-homomorphism from $H^0(X, \mathbb{Z})$ to $K^\circ(X)$: a section a of the constant sheaf $\mathbb{Z}$ partitions the final object into opens U_n on which $a = n$, and is sent to the class of the locally free module which is A^n on U_n for $n \geq 0$, minus the analogous class on the negative pieces. The rank map is the augmentation. This is the augmented structure used below.

3.10. Let A be an augmented K-λ-algebra. For $n > 0$, define $\operatorname{Fil}^n A$ to be the ideal generated by products

$$\gamma^{i_1}(x_1) \cdots \gamma^{i_k}(x_k), \qquad i_1 + \cdots + i_k \geq n, \qquad \epsilon(x_i) = 0. \tag{3.10.1}$$

If A is generated as an abelian group by (x_α), then $\operatorname{Fil}^n A$ is generated over K by

$$\gamma^{i_1}(x_{\alpha_1} - \epsilon(x_{\alpha_1})) \cdots \gamma^{i_k}(x_{\alpha_k} - \epsilon(x_{\alpha_k})), \qquad i_1 + \cdots + i_k \geq n. \tag{3.10.2}$$

The filtration is decreasing and multiplicative, and

$$\operatorname{Fil}^0 A = A, \qquad \operatorname{Fil}^1 A = \operatorname{Ker} \epsilon.$$

It is functorial for homomorphisms of augmented K-λ-algebras.

Proposition 3.11. Let A be a λ-ring and let $y_1, \ldots, y_n$ be elements of A such that $\gamma^j(y_i) = 0$ for $j \geq 2$. Put $x = \sum_i y_i$. Then $\gamma^k(x - n) = 0$ for $k > n$, and, for $1 \leq k \leq n$, $\gamma^k(x - n)$ is the k-th elementary symmetric function of the $y_i - 1$. This follows from

$$\gamma_t(x - n) = \prod_{i=1}^{n} \gamma_t(y_i - 1).$$

4. λ-rings generated by generators and relations

4.1. Let K be a λ-ring and let $(X_i)_{i \in I}$ be indeterminates. Put

$$A = K[X_i, {}^n X_i]_{i \in I,\ n \geq 2}.$$

Define

$$\lambda_t(X_i) = 1 + X_i t + \sum_{n \geq 2} {}^n X_i t^n, \qquad \lambda_t({}^n X_i) = \lambda^n(\lambda_t(X_i)). \tag{4.1.1}$$

This gives a λ-ring structure on A extending that of K.

Proposition 4.2. For every K-λ-algebra B and every family $(b_i)_{i \in I}$ in B, there exists a unique K-λ-homomorphism $A \to B$ carrying X_i to b_i. Necessarily it carries ${}^n X_i$ to $\lambda^n(b_i)$, and this condition is sufficient.

4.3. The same construction may be made using γ's. Let

$$A' = K[X_i, \overset{\gamma}{n} X_i]_{i \in I,\ n \geq 2},$$

and define

$$\gamma_t(X_i) = 1 + X_i t + \sum_{n \geq 2} \overset{\gamma}{n} X_i t^n, \qquad \gamma_t(\overset{\gamma}{n} X_i) = \gamma'^n(\gamma_t(X_i)). \tag{4.3.1}$$

This gives a λ-ring satisfying the same universal property, hence canonically isomorphic to A.

Definition 4.4. The preceding λ-ring is the *free λ-ring* over K generated by the family (X_i).

Definition 4.5. An ideal J of a λ-ring A is a *λ-ideal* if $\lambda^n(x) \in J$ for every $x \in J$ and $n > 1$. Kernels of λ-homomorphisms are λ-ideals; conversely, if J is a λ-ideal, A/J receives a unique λ-ring structure. The intersection of λ-ideals is a λ-ideal. Thus every family of elements has a smallest containing λ-ideal, generated by the elements and all their iterated λ^n's.

Definition 4.6. The quotient of the free λ-ring by the λ-ideal generated by prescribed relations (P_i) is called the λ-ring generated by the generators (X_i) subject to the relations (P_i). Equivalently, one may formulate the same construction in terms of γ-operations.

Proposition 4.7. This quotient has the expected universal property: every family (b_i) in a K-λ-algebra satisfying the relations (P_i) determines a unique K-λ-homomorphism from the quotient to that algebra.

Proposition 4.8. Let $n \geq 0$. In the free λ-ring over K on one generator X, the ideal generated by the $\lambda^k X$, $k > n$, is a λ-ideal. Indeed, after quotienting, one has only to check that if $\varphi \in \widehat{G}(C)$ has no terms of degree $> n$, then $\lambda^k(\varphi) = 0$ for $k > n$. By the splitting principle, it is enough to write

$$\varphi = \prod_{i=1}^{n} (1 + T_i t),$$

and then

$$\lambda_u(\varphi) = \prod_{i=1}^{n} (1 + \{1 + T_i t\} u),$$

which has degree n in u.

Corollary 4.9. The λ-ring generated over K by one element X, subject to $\lambda^k(X) = 0$ for $k > n$, is

$$K[X, \lambda^2 X, \ldots, \lambda^n X].$$

More generally, for a family (X_i) with bounds (n_i), the quotient subject to $\lambda^k(X_i) = 0$ for $k > n_i$ is the polynomial ring generated by $X_i, \lambda^2 X_i,$
$ldots, \lambda^{n_i} X_i$.

4.10. Let K be binomial and let A be an augmented K-λ-algebra. Put

$$B = A[X, \gamma^2 X, \gamma^3 X, \ldots],$$

the free A-λ-algebra on X, written in γ-coordinates. Extend the augmentation by $\epsilon(X) = 0$, hence $\epsilon(\gamma^i X) = 0$ for $i > 0$. Let M_k be the set of monomials in the variables $\gamma^j X$, counted with weight j, of total weight k, and set $M_0 = \{1\}$.

Lemma 4.11. If $x \in \mathrm{Fil}^p A$, then every coefficient of $\gamma^n(x + X)$ which is homogeneous of weight k in the $\gamma^j X$ belongs to $\mathrm{Fil}^{p+n-k} A$.

Proposition 4.12. For every $k \geq 0$,

$$\mathrm{Fil}^k B = \mathrm{Fil}^k A + \mathrm{Fil}^{k-1} A\, M_1 + \cdots + \mathrm{Fil}^1 A\, M_{k-1} + \mathrm{Fil}^0 A\, M_k + B\, M_{k+1}. \tag{4.12.1}$$

The inclusion from right to left follows from Lemma 4.11. The reverse inclusion is obtained by writing the generators of $\mathrm{Fil}^k B$ as products of γ-operations and reducing, term by term, to the displayed weights.

Remarks 4.13. The proof gives the same assertion for a free λ-algebra on any finite or infinite family of generators, with the evident multi-weight. It is also unchanged when one uses the λ-coordinates, since λ and γ coordinates differ by triangular universal formulas.

Corollary 4.14. Passing to the associated graded ring, one has

$$\mathrm{Gr}^k B \simeq \mathrm{Gr}^k A \oplus \mathrm{Gr}^{k-1} A\, M_1 \oplus \cdots \oplus \mathrm{Gr}^0 A\, M_k. \tag{4.14.1}$$

Corollary 4.15. If $B' = K[X, \gamma^2 X, \ldots, \gamma^n X]$ is the K-λ-algebra generated by one element satisfying $\gamma^k(X) = 0$ for $k > n$, then the λ-ring filtration of B' is exactly the weight filtration in the variables $\gamma^j X$.

5. The elements $\lambda^p(N, x)$

This section will be used only in Exposé VII, §4, in the study of regular immersions; it may be omitted on first reading.

5.1. Let $d \geq 1$. Let A be the $\mathbb{Z}$-λ-algebra generated by N and x, subject to the relations $\lambda^i(N) = 0$ for $i > d$. Thus

$$A = \mathbb{Z}[N, \ldots, \lambda^d N; x, \ldots, \lambda^j x, \ldots].$$

Put

$$\lambda_{-1}(N) = \sum_{i=0}^{d} (-1)^i \lambda^i(N). \tag{5.1.1}$$

Lemma 5.2. For every $p \geq 1$, the element $\lambda^p(x\lambda_{-1}(N))$ is divisible by $\lambda_{-1}(N)$.

It is enough, by isobaricity, to prove this for $\lambda^p(\lambda_{-1}(N))$. Let B be the λ-ring generated by $N_1, \dots, N_d$, with $\lambda^i(N_j) = 0$ for $i \geq 2$. The map $N \mapsto \sum_i N_i$ identifies A with the symmetric polynomials in the N_i, and

$$\lambda_{-1}(N) = \prod_{i=1}^{d} (1 - N_i).$$

If some $N_i = 1$, then $\lambda_t(\lambda_{-1}(N)) = \lambda_t(0) = 1$, so every positive coefficient vanishes. Thus each $\lambda^p(\lambda_{-1}(N))$ is divisible by every $1 - N_i$, hence by their product.

Definition 5.3. Since A is integral, define $\lambda^p(N, x)$ by

$$\lambda^p(N, x)\lambda_{-1}(N) = \lambda^p(x\lambda_{-1}(N)), \qquad p \geq 1. \tag{5.3.1}$$

Thus $\lambda^p(N, x)$ is a polynomial in the $\lambda^i(x)$ and $\lambda^j(N)$, isobaric of weight p in the $\lambda^i(x)$. If a λ-ring B contains an element N' with $\lambda^k(N') = 0$ for $k > d$, then $\lambda^p(N', x')$ is defined by substitution; it is independent of the chosen bound d.

5.4. In the λ-ring generated over $\mathbb{Z}$ by N, x, y, subject to $\lambda^k(N) = 0$ for $k > d$, formula (5.3.1) gives

$$\begin{aligned}
\lambda^p(N, x+y)\lambda_{-1}(N) &= \lambda^p\big((x+y)\lambda_{-1}(N)\big) \\
&= \sum_{i+j=p} \lambda^i\big(x\lambda_{-1}(N)\big)\lambda^j\big(y\lambda_{-1}(N)\big) \\
&= \sum_{\substack{i+j=p \\ i,j\neq 0}} \lambda^i(N, x)\lambda^j(N, y)\big(\lambda_{-1}(N)\big)^2 + \big(\lambda^p(N, x) + \lambda^p(N, y)\big)\lambda_{-1}(N).
\end{aligned}$$

Since the ring under consideration is an integral domain, this yields the relation, valid by substitution in every λ-ring,

$$\lambda^p(N, x+y) = \sum_{\substack{i+j=p \\ i,j\neq 0}} \lambda^i(N, x)\lambda^j(N, y)\lambda_{-1}(N) + \lambda^p(N, x) + \lambda^p(N, y). \tag{5.4.1}$$

Now consider the λ-ring generated over $\mathbb{Z}$ by N, N', x, subject to $\lambda^k(N) = 0$ for $k > d$ and $\lambda^k(N') = 0$ for $k > d'$. Then $\lambda^k(N + N') = 0$ for $k > d + d'$, and

$$\begin{aligned}
\lambda^p(N + N', x)\lambda_{-1}(N)\lambda_{-1}(N') &= \lambda^p\big(x\lambda_{-1}(N)\lambda_{-1}(N')\big) \\
&= \lambda^p\big(N', x\lambda_{-1}(N)\big)\lambda_{-1}(N').
\end{aligned}$$

Here we used $\lambda_{-1}(N + N') = \lambda_{-1}(N)\lambda_{-1}(N')$. Cancelling in the integral domain gives the relation, again valid by substitution,

$$\lambda^p(N + N', x)\lambda_{-1}(N) = \lambda^p\big(N', x\lambda_{-1}(N)\big). \tag{5.4.2}$$

5.5. Let A be a λ-ring and let $N \in A$ satisfy $\lambda^k(N) = 0$ for $k > d$. Define on the underlying abelian group of A a new multiplication by

$$x \cdot_N y = xy\lambda_{-1}(N).$$

After adjoining a unit, one obtains a ring $\mathbb{Z} \times A$ with

$$(n, x)(m, y) = (nm, ny + mx + x \cdot_N y).$$

The formulas

$$\lambda_t(n, x) = (1+t)^n \left(1 + \sum_{p\geq 1} \lambda^p(N, x)t^p\right) \tag{5.5.1}$$

define a pre-λ-ring structure. In fact, when A is a λ-ring, this is a λ-ring structure; it is the one transported from the original structure by multiplication by $\lambda_{-1}(N)$. We denote this augmented λ-ring by $\widehat{A}_N$. Its γ-operations satisfy

$$\gamma^p(N,x)\lambda_{-1}(N) = \gamma^p(x\lambda_{-1}(N)). \tag{5.5.2}$$

5.6. Suppose that, in addition, L is an element such that $\lambda^k(L) = 0$ for $k > 1$. Then $\lambda^p(N+L,x)$ is the coefficient of t^p in the series

$$\frac{\sum_{k\geq 1} \lambda^k(N,x)(1 + L + \cdots + L^{k-1})t^k}{1 + \sum_{k\geq 1} \lambda^k(N,x)\lambda_{-1}(N)L^k t^k}. \tag{5.6.1}$$

This is obtained by applying (5.4.2) to $N + L$ and using $\lambda_{-1}(L) = 1 - L$.

Proposition 5.7. Let K be a binomial ring, A an augmented K-λ-algebra, and $N \in A$ such that $\lambda^k(N) = 0$ for $k > d$. Then, for every $x \in A$ and every $p \geq 1$,

$$\gamma^p(N,x) \in \mathrm{Fil}^{p-d} A. \tag{5.7.1}$$

Indeed, let A_0 be the K-λ-algebra generated by N_0', X_0', subject to $\gamma^k(N_0') = 0$ for $k > d$, and augmented by $\epsilon(N_0') = \epsilon(X_0') = 0$. This is a polynomial algebra over K in the variables $\gamma^i(N_0')$, $1 \leq i \leq d$, and $\gamma^j(X_0')$, $j \geq 1$, and its λ-filtration is the weight filtration, with weight i assigned to $\gamma^i(N_0')$ and $\gamma^i(X_0')$ (4.12 and 4.15). Put

$$N_0 = N_0' + d, \qquad X_0 = X_0' + \epsilon(x).$$

For N_0, X_0, the assertion is equivalent to

$$\gamma^p(N_0, X_0)\gamma^d(N_0') \in \mathrm{Fil}^p A_0.$$

Since $\gamma^d(N_0') = (-1)^d\lambda_{-1}(N_0)$, this becomes

$$(-1)^d\gamma^p(X_0\gamma^d(N_0')) \in \mathrm{Fil}^p A_0,$$

by (5.5.4). This holds because $\gamma^d(N_0')$ has zero augmentation. By 4.7 there is a K-λ-homomorphism $A_0 \to A$, compatible with augmentations and sending N_0' to $N - d$ and X_0' to $x - \epsilon(x)$, hence sending N_0 to N and X_0 to x. Compatibility with the filtrations gives the result.

6. Chern ring: opening

Throughout this section the base ring is a fixed binomial ring K. We use the functor G of 1.1, and return to the notation of §1: G denotes the functor there defined and G_i its restriction to $\mathscr{C}_0$.

6.1. In 3.5 and 3.6 we defined morphisms of functors

$$G_i \times G_i \xrightarrow{\star} G_i, \qquad G_i^\circ \xrightarrow{\gamma'} G_i^\circ \circ G_S, \qquad G_i \xrightarrow{a} G_i,$$

where the last map is multiplication, for the law ∇, by $\gamma_t(a)$ with $a \in K$. By 1.9 these give morphisms

$$G \times G \xrightarrow{\star} G, \qquad G \xrightarrow{\gamma'} G \circ G_S, \qquad G \xrightarrow{a} G.$$

The isobaricity of the universal polynomials involved implies that the first and third images lie in G, while the second lies in the subgroup of formal series in u whose non-zero terms have the prescribed degrees.

Exposé V, 6. Chern ring: completion

Definition 6.2. The functor defined in 6.1 on the category of graded K-algebras, with values in the category of K-λ-algebras, is called the *Chern ring*; its value on $A \in \mathrm{Ob}(\mathscr{C})$ is denoted $\mathrm{Ch}(A)$, or, if there is a risk of confusion, $\mathrm{Ch}_K(A)$.

From formulas (6.1.1), (6.1.2), (6.1.4), and (3.6.2), one deduces the relations

$$(1, 1+X)(1, 1+Y) = (1, 1+X+Y), \qquad \lambda^i(1, 1+X) = 0 \quad \text{for } i \geq 2, \tag{6.2.1}$$

the relations which served in [1] to define the Chern ring. Conversely, from these formulas one can recover the relations (6.1.1) and (6.1.4).

Let us indicate why the Chern ring is introduced. We place ourselves in the situation of Example 3.9, and write A for the graded ring associated, by the filtration defined in 3.10, with the $K^\bullet$ of a commutatively locally ringed topos; for simplicity suppose that $K^\bullet$ is a λ-ring. The augmentation ring is K. We shall see below that for every element of an augmented λ-ring one can define Chern classes with values in the associated graded ring (6.7). To every locally free sheaf of finite type one can therefore associate an element of $\mathrm{Ch}(A)$, whose component on the factor K is the rank of the sheaf and whose component on the factor $1 + \widehat{A}^+$ is the sum of the Chern classes. Formulas (6.2.1) are then the usual formulas giving the Chern classes and the rank of the tensor product of two invertible sheaves and of the exterior powers of an invertible sheaf; in other words, the map just defined from $K^\bullet$ to $\mathrm{Ch}(A)$ is a λ-homomorphism.

6.3. For every graded K-algebra A, denote by $A_\mathbb{Q}$ the K-algebra $A \otimes \mathbb{Q}$, graded in the evident way. By 1.13 one defines a functorial homomorphism

$$1 + \widehat{A}^+ \xrightarrow{\mathrm{ch}} \widehat{A}^+_\mathbb{Q}$$

by giving its value on $1 + X$:

$$\mathrm{ch}(1+X) = \exp(X) - 1. \tag{6.3.1}$$

This homomorphism is compatible with the multiplication defined in 6.1 on $1 + \widehat{A}^+$. By 1.13 it is enough to show this for the elements $1 + X$, $1 + Y$ of the universal ring $1 + K[X, Y]^+$. One has

$$\begin{aligned}
\mathrm{ch}\big((1+X) * (1+Y)\big) &= \mathrm{ch}\left(\frac{1+X+Y}{(1+X)(1+Y)}\right) \\
&= \mathrm{ch}(1+X+Y) - \mathrm{ch}(1+X) - \mathrm{ch}(1+Y) \\
&= \exp(X+Y) - \exp(X) - \exp(Y) + 1 \\
&= \mathrm{ch}(1+X)\ \mathrm{ch}(1+Y).
\end{aligned}$$

Let η be the endomorphism of $\widehat{A}^+_\mathbb{Q}$, functorial in A, defined by

$$\eta\left(\sum_{k\geq 1} a_k t^k\right) = \sum_{k\geq 1} \frac{(-1)^{k-1}}{(k-1)!}\, a_k t^k.$$

Then, for every $\varphi \in 1 + \widehat{A}^+$,

$$\mathrm{ch}(\varphi) = \eta(\mathrm{Log}\,\varphi). \tag{6.3.2}$$

Indeed, ch and $\eta \circ \mathrm{Log}$ are two functorial homomorphisms of abelian groups, and it is enough for them to agree on $1 + X$, which is evident.

It follows that ch commutes with the operations of K: again it is enough to show this for $1+X$, and for $a \in K$ one has

$$\begin{aligned}\mathrm{ch}((1+X)^a) &= \mathrm{ch}(\exp(a\,\mathrm{Log}(1+X))) \\ &= \eta(a\,\mathrm{Log}(1+X)) \\ &= a\,\eta(\mathrm{Log}(1+X)) \\ &= a\ \mathrm{ch}(1+X).\end{aligned}$$

Thus one can extend ch in the evident way to a homomorphism of K-algebras

$$K \times (1+\widehat{A}^+) \longrightarrow K \oplus \widehat{A}^+_{\mathbb{Q}},$$

namely

$$\mathrm{ch}(a,\varphi) = a + \eta(\mathrm{Log}\,\varphi). \tag{6.3.3}$$

Definition 6.4. The homomorphism

$$\mathrm{ch} : \mathrm{Ch}\,A \longrightarrow K \oplus \widehat{A}^+_{\mathbb{Q}}$$

just defined is called the *Chern character*.

If A is of characteristic zero, that is, is a $\mathbb{Q}$-algebra, the Chern character is an isomorphism. Indeed, if $\psi \in K \oplus \widehat{A}^+$, one may write $\psi = a + \psi_1$, where ψ_1 is of positive degree, and then an inverse morphism is defined by

$$\psi \longmapsto (a, \exp(\eta^{-1}(\psi_1))).$$

Proposition 6.5. Let A be a graded K-algebra. On $\mathrm{Ch}(A)$ consider the filtration defined as follows, the degree filtration:

$$(\mathrm{Ch}(A))_0 = \mathrm{Ch}(A), \qquad (\mathrm{Ch}(A))_n = 0 \times (1+\widehat{A}^{\geq n}) \quad (n \geq 1), \tag{6.5.1}$$

where $\widehat{A}^{\geq n} = \prod_{i \geq n} A^i$. The following congruences hold.

i) If $n \geq 1$ and $\varphi \in (\mathrm{Ch}\,A)_n$, writing $\varphi = 1 + a_n + \cdots$, then

$$\mathrm{ch}(\varphi) = \frac{(-1)^{n-1}}{(n-1)!}\,a_n + \cdots . \tag{6.5.2}$$

ii) If $\varphi \in (\mathrm{Ch}\,A)_m$, $\psi \in (\mathrm{Ch}\,A)_n$, and if $\varphi = 1 + a_m + \cdots$, $\psi = 1 + b_n + \cdots$, then

$$\varphi * \psi = 1 - \frac{(m+n-1)!}{(m-1)!(n-1)!}\,a_m b_n + \cdots . \tag{6.5.3}$$

Consequently the degree filtration is a ring filtration.

For (i), the Chern character is by construction a morphism of filtered functors; from the congruence $\varphi \equiv 1 + a_n \pmod{(\mathrm{Ch}\,A)_{n+1}}$ one obtains

$$\mathrm{ch}(\varphi) = \mathrm{ch}(1+a_n) \pmod{\widehat{A}^{\geq n+1}},$$

and, since $\mathrm{ch}(1+a_n) = \eta(\mathrm{Log}(1+a_n))$, this is

$$\frac{(-1)^{n-1}}{(n-1)!}a_n + \cdots .$$

For (ii), by substitution it is enough to prove (6.5.3) for the torsion-free universal polynomial algebra

$$A = K[X_i, Y_j]_{i,j\in\mathbb{N}}$$

and for $\varphi = 1+\sum_{k\geq m} X_k$, $\psi = 1+\sum_{k\geq n} Y_k$. Since K is torsion-free in the universal case, one can embed this algebra in its tensor product with $\mathbb{Q}$, so that ch is injective. Put $\varphi * \psi = 1 + Z_p + \cdots$, where Z_p is the first non-zero term different from 1. The multiplicativity of ch, together with (6.5.2), gives

$$1 + \frac{(-1)^{p-1}}{(p-1)!} Z_p + \cdots = \left(1 + \frac{(-1)^{m-1}}{(m-1)!} X_m + \cdots\right)\left(1 + \frac{(-1)^{n-1}}{(n-1)!} Y_n + \cdots\right),$$

which gives the stated value of Z_p by comparing the terms of lowest degree.

6.6. The λ-ring $\mathrm{Ch}\, A$ is augmented over K: one defines a λ-homomorphism $\mathrm{Ch}\, A \to K$ by $(a, \varphi) \mapsto a$. It is therefore equipped with the canonical filtration of an augmented λ-ring. We compare it with the filtration just defined.

Proposition 6.6.1. Let $x \in \mathrm{Ch}\, A$ be an element of the form $x = (n, 1 + \cdots + a_n)$. Then:

i) $\lambda^i(x) = 0 \quad \text{for } i > n,$

ii) $\lambda^n(x) = (1, 1 + a_1),$

iii) $\displaystyle\sum_{i=0}^{n} (-1)^i \lambda^i(x) = (0, 1 - (n-1)! a_n + \cdots),$

where the unwritten terms have degree $> n$.

By functoriality, it is enough to prove this in the case where $A = K[X_1, \ldots, X_n]$, filtered by weight with respect to the X_i, X_i having weight i, and for the element $(n, 1 + X_1 + \cdots + X_n)$. Embed A in $A' = K[T_1, \ldots, T_n]$ by the symmetric functions. Then

$$(n, 1 + X_1 + \cdots + X_n) = \left(n, \prod_{i=1}^{n} (1 + T_i)\right) = \sum_{i=1}^{n} (1, 1 + T_i).$$

Hence, by (6.2.1),

$$\lambda_t(x) = \prod_{i=1}^{n} (1 + (1, 1 + T_i)t),$$

so that

$$\lambda^k(x) = 0 \quad (k > n), \qquad \lambda^n(x) = \prod_{i=1}^{n} (1, 1 + T_i) = \left(1, 1 + \sum_{i=1}^{n} T_i\right) = (1, 1 + X_1).$$

Finally,

$$\sum_{i=1}^{n} (-1)^i \lambda^i(x) = \lambda_{-1}(x) = \prod_{i=1}^{n} (1 - (1, 1 + T_i)) = (-1)^n \prod_{i=1}^{n} (0, 1 + T_i).$$

By (6.5.3),

$$\prod_{i=1}^{n} (0, 1 + T_i) = \left(0, 1 + (-1)^{n-1}(n-1)! \prod_{i=1}^{n} T_i + \cdots\right),$$

hence

$$\lambda_{-1}(x) = (0, 1 - (n-1)! X_n + \cdots).$$

Corollary 6.6.2. Relation 6.6.1(iii) is true for every element X of augmentation n.

For this we shall use the following lemma.

Lemma 6.6.3. For every n, $(\mathrm{Ch}\, A)_n$ is a λ-ideal of $\mathrm{Ch}\, A$.

We may suppose $n > 1$. Let $x = (0, \varphi) \in (\mathrm{Ch}\, A)_n$, and write

$$\lambda^i(0, \varphi) = (0, 1 + Q^i_{i,1} + \cdots + Q^i_{i,j} + \cdots),$$

where the $Q^i_{i,j}$ are the isobaric components of weight j of the Q^i_i of (3.6). For every j, the polynomial $Q^i_{i,j}$ is a polynomial in the first j coefficients of φ. If $j < n$, these coefficients are zero; hence the $Q^i_{i,j}$ are zero, and so the $\lambda^i(x)$ belong to $(\mathrm{Ch}\, A)_n$. Thus $(\mathrm{Ch}\, A)_n$ is a λ-ideal.

Let $x = (n, 1 + a_1 + \cdots + a_n + \cdots)$ be an element of augmentation n in $\mathrm{Ch}\, A$. Then

$$x \equiv (n, 1 + \cdots + a_n) \pmod{(\mathrm{Ch}\, A)_{n+1}},$$

and therefore

$$\lambda_{-1}(x) \equiv \lambda_{-1}(n, 1 + \cdots + a_n) = (0, 1 - (n-1)!a_n + \cdots),$$

which proves the corollary.

Corollary 6.6.4. Let ϵ be the augmentation homomorphism of $\mathrm{Ch}\, A$. Then, for every $x \in \mathrm{Ch}\, A$, one has

$$\gamma^n(x - \epsilon(x)) = (0, 1 + (-1)^{n-1}(n-1)!a_n + \cdots).$$

By definition,

$$\gamma^n(x - \epsilon(x)) = (-1)^n \sum_{i=0}^{n} (-1)^i \lambda^i(x + n - \epsilon(x)).$$

Since $x + n - \epsilon(x)$ has augmentation n, Corollary 6.6.2 applies to it, giving the result.

Corollary 6.6.5. With the notation of 3.10,

$$\mathrm{Fil}^n\, \mathrm{Ch}\, A \subset (\mathrm{Ch}\, A)_n.$$

This follows from the preceding corollary, which gives $\gamma^n(x - \epsilon(x)) \in (\mathrm{Ch}\, A)_n$, and from the fact that the two filtrations are ring filtrations and that the elements $\gamma^n(x - \epsilon(x))$, for n and x variable, generate the λ-ring filtration.

Corollary 6.6.7. Let A be a graded K-algebra of characteristic zero, bounded by degree. Then the two filtrations defined on $\mathrm{Ch}\, A$ are identical.

Suppose that $\mathrm{Fil}^p A = 0$, and let $x = (0, 1 + a_n + \cdots + a_p)$ be an element of $(\mathrm{Ch}\, A)_n$. Put

$$x' = \left(0, 1 + \frac{(-1)^{n-1}}{(n-1)!}a_n + a_{n+1} + \cdots + a_p\right).$$

Then $\gamma^n(x') = (0, 1 + a_n + \cdots + a'_p)$, since x' has zero augmentation. Hence $x - \gamma^n(x') \in (\mathrm{Ch}\, A)_{n+1}$. Iterating the operation $p - n$ times, one reaches $(\mathrm{Ch}\, A)_{p+1} = 0$, and therefore x is written as an element of $\mathrm{Fil}^n\, \mathrm{Ch}\, A$. In view of (6.6.5), the two filtrations are identical.

6.7. Now suppose that A is a λ-ring augmented over K, and let ϵ be the augmentation homomorphism. Then A is equipped with its canonical filtration of augmented λ-ring, and one can associate to $\mathrm{Gr}\, A$ its Chern ring.

If $x \in A$, then $\gamma_t(x - \epsilon(x)) \in \widehat{G}(A)$ by definition of the filtration of an augmented λ-ring. We write $c(x)$ for the image of $\gamma_t(x - \epsilon(x))$ in

$$\widehat{G}(A)/\widehat{G}'(A) = 1 + \widehat{\mathrm{Gr}\, A}^+.$$

It is called the *total Chern class* of x. We write $c^i(x)$, and call it the i-th Chern class of x, for the i-th coefficient of $c(x)$. Thus

$$c^i(x) = \mathrm{cl}_{\mathrm{Gr}^i A}\Big(\gamma^i(x - \epsilon(x))\Big), \qquad c(x) = 1 + c^1(x) + \cdots . \tag{6.7.1}$$

Put

$$\widetilde{c}(x) = (\epsilon(x), c(x)). \tag{6.7.2}$$

This is called the *completed Chern class* of x.

Proposition 6.8. The completed Chern class

$$\widetilde{c} : A \longrightarrow \mathrm{Ch}(\mathrm{Gr}\, A)$$

is a K-λ-homomorphism of augmented K-λ-algebras.

It is clear that the homomorphism so defined is additive. To verify that it is multiplicative, write

$$\begin{aligned}\gamma_t(xy - \epsilon(xy)) &= \gamma_t(\epsilon(y)(x - \epsilon(x)))\gamma_t(\epsilon(x)(y - \epsilon(y)))\gamma_t((x - \epsilon(x))(y - \epsilon(y))) \\ &= (\gamma_t(x - \epsilon(x)))^{\epsilon(y)}(\gamma_t(y - \epsilon(y)))^{\epsilon(x)}(\gamma_t(x - \epsilon(x)) \circ \gamma_t(y - \epsilon(y))),\end{aligned}$$

which gives the result by (6.1.2) after passage to the quotient. If $a \in K$, then $\widetilde{c}(a) = (a, 1)$, so $\widetilde{c}$ is a homomorphism of K-algebras; moreover it is compatible with augmentations.

It remains to see that it is a λ-homomorphism. One must prove the commutativity of the diagram

$$\begin{array}{ccc} A & \xrightarrow{\gamma_t} & \widehat{G}(A) \\ \Big\downarrow{\scriptstyle \widetilde{c}} & & \Big\downarrow{\scriptstyle \widehat{G}(\widetilde{c})} \\ \mathrm{Ch}\, A & \xrightarrow[\gamma_t]{} & \widehat{G}(\mathrm{Ch}\, A). \end{array}$$

By additivity, it is enough to prove it for the elements of K, where it is evident, and for the elements of zero augmentation in A, where it follows, by the definition of c and (6.1.4), from diagram (3.7.2).

Proposition 6.9. Let A be an augmented K-λ-algebra and let $z \in \mathrm{Fil}^m A$. Then

$$\gamma^m(z) = (-1)^{m-1}(m-1)!z \pmod{\mathrm{Fil}^{m+1} A},$$

that is,

$$c^m(z) = \mathrm{cl}_{\mathrm{Gr}^m A}\Big((-1)^{m-1}(m-1)!z\Big).$$

One must see that these two elements give the same image in $\mathrm{Gr}^m A$, that is, that the m-th Chern class of z is the image of $(-1)^{m-1}(m-1)!z$.

One may write z as a sum

$$\sum a\, \gamma^{i_1}(x_1) \cdots \gamma^{i_k}(x_k),$$

with $a \in A$, $\epsilon(x_i) = 0$ for all i, and $i_1 + \cdots + i_k \geq m$. We then have

$$\widetilde{c}(z) = \sum \widetilde{c}(a)\, \widetilde{c}(\gamma^{i_1}(x_1)) \cdots \widetilde{c}(\gamma^{i_k}(x_k)).$$

Since $\widetilde{c}$ is a λ-homomorphism, one may write

$$\widetilde{c}(\gamma^i(x_j)) = \gamma^i(\widetilde{c}(x_j)).$$

Taking account of the definition of c and of (6.6.4), one obtains

$$\widetilde{c}(\gamma^{i_j}(x_j)) = \left(0, 1 + (-1)^{i_j-1}(i_j-1)!\,\gamma^{i_j}(x_j) + \cdots\right).$$

By (6.5.3), and since $\widetilde{c}(a) = (a, 1)$, one finally gets

$$\begin{aligned}\widetilde{c}(z) &= \sum \left(0, \left(1 + (-1)^{i_1+\cdots+i_k-1}(i_1+\cdots+i_k-1)!\,\gamma^{i_1}(x_1)\cdots\gamma^{i_k}(x_k) + \cdots\right)^a\right) \\ &= \left(0, 1 + \sum_{\substack{(x_1,\ldots,x_k)\\ i_1+\cdots+i_k=m}} (-1)^{m-1}(m-1)!a\,\gamma^{i_1}(x_1)\cdots\gamma^{i_k}(x_k) + \cdots\right) \\ &= (0, 1 + (-1)^{m-1}(m-1)!z + \cdots),\end{aligned}$$

which proves the assertion.

Proposition 6.10. Let K be a binomial ring, R an augmented K-λ-algebra, $N \in R$ an element such that $\lambda^k(N) = 0$ for $k > d$, and $x \in \mathrm{Fil}^i R$. Then

$$\gamma^{d+i}(N, x) - (-1)^{d+i-1}(d+i-1)!x \in \mathrm{Fil}^{i+1} R.$$

One can find elements $z_{\alpha,j} \in R$ and $a_\alpha \in K$ such that

$$x = \sum_\alpha a_\alpha\,\gamma^{i_1}(x_{\alpha,1})\cdots\gamma^{i_k}(x_{\alpha,k}),$$

with $i_1 + \cdots + i_k \geq i$ and $\epsilon(x_{\alpha,j}) = 0$ for every α and every j. Let R_0 be the K-λ-algebra generated by N_0' and $X_{\alpha,j}$, subject to the relations

$$\gamma^k(N_0') = 0 \quad \text{for } k > d.$$

Define an augmentation homomorphism $R_0 \to K$ by $\epsilon(N_0') = \epsilon(X_{\alpha,j}) = 0$. By (4.9.1), R_0 is the ring of polynomials with coefficients in K in the indeterminates $\gamma^k(N_0')$, $1 \leq k \leq d$, and $\gamma^p(X_{\alpha,j})$, $p \geq 1$; the λ-filtration of R_0 is its weight filtration, where $\gamma^k(N_0')$ and $\gamma^k(X_{\alpha,j})$ have weight k (4.12 and 4.15).

Put

$$X_0 = \sum_\alpha a_\alpha\,\gamma^{i_1}(X_{\alpha,1})\cdots\gamma^{i_k}(X_{\alpha,k}).$$

We shall prove 6.10 first for X_0 and $N_0' = N_0 + d$, which do satisfy the hypotheses of 6.10. In view of the preceding remark about the filtration of R_0, it is enough to show that

$$\gamma^{d+i}(N_0, X_0)\gamma^d(N_0') - (-1)^{d+i-1}(d+i-1)!X_0\gamma^d(N_0') \in \mathrm{Fil}^{d+i+1} R_0.$$

But $\lambda_{-1}(N_0) = (-1)^d\gamma^d(N_0')$. Thus this relation becomes

$$(-1)^d\gamma^{d+i}(X_0, (-1)^d\gamma^d(N_0')) - (-1)^{d+i-1}(d+i-1)!X_0\gamma^d(N_0') \in \mathrm{Fil}^{d+i+1} R_0.$$

Putting $z = (-1)^d X_0\gamma^d(N_0')$, we have $z \in \mathrm{Fil}^{d+i} R_0$, and the statement is reduced to

$$\gamma^{d+i}(z) - (-1)^{d+i-1}(d+i-1)!z \in \mathrm{Fil}^{d+i+1} R_0,$$

which is just 6.9.

To deduce 6.10 from this particular case, consider the K-λ-homomorphism $R_0 \to R$ which sends N_0' to $N - d$ and $X_{\alpha,j}$ to $x_{\alpha,j}$, for every α and j. This homomorphism is compatible with the λ-filtrations and sends N_0 to N and X_0 to x. Hence the result follows.

Proposition 6.11. Suppose that K is of characteristic zero, and let $n \geq 0$ be an integer. Then the functor Ch is an equivalence from the category of graded K-algebras A such that $A_0 = K$ and $A_k = 0$ for $k > n$, to the category of augmented K-λ-algebras Λ such that $\mathrm{Fil}^{n+1}\,\Lambda = 0$. A quasi-inverse functor is given by $\Lambda \mapsto \mathrm{Gr}\,\Lambda$.

Let A be a graded K-algebra such that $A_k = 0$ for $k > n$, equipped with the filtration associated to its grading. Then $(\mathrm{Ch}\,A)_{n+1} = 0$, and hence $\mathrm{Fil}^{n+1}\,\mathrm{Ch}\,A = 0$ by (6.6.5). Conversely, if Λ is an augmented K-λ-algebra such that $\mathrm{Fil}^{n+1}\,\Lambda = 0$, then $\mathrm{Gr}^0\,\Lambda = K$ and $\mathrm{Gr}^k\,\Lambda = 0$ for $k > n$.

We shall define isomorphisms of functors

$$A \longrightarrow \mathrm{Gr}(\mathrm{Ch}\,A), \qquad \Lambda \longrightarrow \mathrm{Ch}(\mathrm{Gr}\,\Lambda).$$

Since A is of finite grading, the associated gradeds of the λ-ring filtration on $\mathrm{Ch}\,A$ and of the degree filtration are the same by (6.6.7). Define

$$u : A \longrightarrow \mathrm{Gr}_{\mathrm{deg}}(\mathrm{Ch}\,A)$$

to be the identity on A_0, and, for $i \geq 1$ and $a_i \in A_i$,

$$u(a_i) = \mathrm{cl}_{\mathrm{Gr}^i}\left(0, 1 + (-1)^{i-1}(i-1)!a_i\right),$$

then extend by additivity. By relation (6.5.3) this is a homomorphism of graded rings, and it is easy to see that it is compatible with the operations of K. The inverse morphism u^{-1} may be defined as follows: for $i \geq 1$ and $\bar{\varphi} \in \mathrm{Gr}^i(\mathrm{Ch}\,A)$, the i-th coefficient a_i of φ is independent of the lift of $\bar{\varphi}$ in $(\mathrm{Ch}\,A)_i$, and one puts

$$u^{-1}(\bar{\varphi}) = \frac{(-1)^{i-1}}{(i-1)!}a_i.$$

Thus u is an isomorphism.

The isomorphism $\Lambda \to \mathrm{Ch}(\mathrm{Gr}\,\Lambda)$ is defined by the completed Chern class $\widetilde{c}$. To verify that it really defines an isomorphism, it is enough to verify that the homomorphism obtained by passing to associated graded rings is one, the filtrations being discrete. One gets

$$\mathrm{Gr}\,\Lambda \xrightarrow{\mathrm{Gr}(\widetilde{c})} \mathrm{Gr}_\lambda(\mathrm{Ch}(\mathrm{Gr}\,\Lambda)) \simeq \mathrm{Gr}_{\mathrm{deg}}(\mathrm{Ch}(\mathrm{Gr}\,\Lambda)) \xrightarrow{u^{-1}} \mathrm{Gr}\,\Lambda.$$

It remains to show that the composite is the identity. Since the homomorphisms are homomorphisms of graded K-algebras, it is enough, by the definition of the λ-ring filtration of Λ, to show that it is the identity on the $\gamma^i(x)$, where $\epsilon(x) = 0$. One then obtains

$$\mathrm{Gr}(\widetilde{c})(\gamma^i(x)) = \mathrm{cl}_{\mathrm{Gr}^i}(\gamma^i(c(x))).$$

But $\gamma^i(\widetilde{c}(x)) = (0, 1 + (-1)^{i-1}(i-1)!c^i(x) + \cdots)$, by (6.6.4). Therefore

$$\mathrm{cl}_{\mathrm{Gr}^i}(\gamma^i(\widetilde{c}(x))) = u(c^i(x)),$$

which shows that $u^{-1} \circ \mathrm{Gr}(\widetilde{c}) = \mathrm{Id}$.

Corollary 6.12. If K is of characteristic zero, and if Λ is a K-λ-algebra with discrete filtration, then the completed Chern class

$$\widetilde{c} : \Lambda \longrightarrow \mathrm{Ch}(\mathrm{Gr}\,\Lambda)$$

is an isomorphism.

The proof is contained in that of 6.11.

Definition 6.13. Let A be a graded K-algebra and Λ an augmented K-λ-algebra. A *Chern theory for Λ with values in A* is a λ-homomorphism

$$\Lambda \longrightarrow \mathrm{Ch}(A)$$

compatible with augmentations.

Thus one defines a functor on the category of graded K-algebras, with values in the category of sets, by associating with a graded K-algebra A the set of Chern theories of Λ with values in A, namely

$$\mathrm{Hom}_\lambda(\Lambda, \mathrm{Ch}(A)).$$

Proposition 6.14. The functor defined in 6.13 is representable. If K is of characteristic zero and Λ has discrete filtration, it is represented by the graded ring associated with Λ.

First prove the first assertion. Consider the graded K-algebra generated by generators $c^i(x)$, with $i \geq 1$, $x \in \mathrm{Fil}^1 \Lambda$, $c^i(x)$ of degree i, and take its quotient by the following relations:

$$\begin{aligned}
&\text{i)} \quad c^k(x+y) = \sum_{i+j=k} c^i(x)c^j(y), \quad k \geq 1,\ x, y \in \mathrm{Fil}^1 \Lambda,\\
&\text{ii)} \quad c^k(xy) = P''_k(c^i(x), c^j(y)) \quad \text{(cf. 6.1)}, \quad k \geq 1,\ x, y \in \mathrm{Fil}^1 \Lambda,\\
&\text{iii)} \quad c^k(ax) = R_{k,a}(c^i(x)) \quad \text{(cf. 6.1)}, \quad k \geq 1,\ a \in K,\ x \in \mathrm{Fil}^1 \Lambda,\\
&\text{iv)} \quad c^k(\gamma^j(x)) = Q''_{j,k}(c^i(x)) \quad \text{(cf. 6.1)}, \quad j, k \geq 1,\ x \in \mathrm{Fil}^1 \Lambda.
\end{aligned}$$

These relations are isobaric, so the quotient is a graded K-algebra Ω. Define a morphism

$$\widetilde{c}_0 : \Lambda \longrightarrow \mathrm{Ch}(\Omega)$$

by

$$x \longmapsto (\epsilon(x), 1 + c^1(x - \epsilon(x)) + \cdots).$$

The imposed relations show that this is a Chern theory for Λ with values in Ω. Conversely, if f is a Chern theory with values in a graded K-algebra A, then there is a unique homomorphism $\Omega \to A$ through which f factors through $\mathrm{Ch}(\Omega)$: it sends, for every $i \geq 1$ and every $x \in \mathrm{Fil}^1 \Lambda$, the element $c^i(x)$ to the i-th coefficient of $f(x)$. This is well defined because f is a λ-homomorphism.

Now suppose that K is of characteristic zero and Λ has discrete filtration. Let n be such that $\mathrm{Fil}^n \Lambda = 0$. Then the graded algebra Ω is zero in degrees $> n$. To show this, it is enough to prove that, for

$$x_1, \ldots, x_p \in \mathrm{Fil}^1 \Lambda \quad \text{and} \quad k_1 + \cdots + k_p \geq n,$$

one has

$$c^{k_1}(x_1) \cdots c^{k_p}(x_p) = 0.$$

By hypothesis,

$$\gamma^{k_1}(x_1) \cdots \gamma^{k_p}(x_p) = 0.$$

Applying the λ-homomorphism $\widetilde{c}_0$, one gets

$$\gamma^{k_1}(\widetilde{c}_0(x_1)) \cdots \gamma^{k_p}(\widetilde{c}_0(x_p)) = (0, 1).$$

By (6.6.4) and (6.5.3), this implies

$$(k_1 + \cdots + k_p)!\, c^{k_1}(x_1) \cdots c^{k_p}(x_p) = 0.$$

Since K is of characteristic zero, the desired result follows.

The universal property of Ω, applied to the canonical homomorphism $\widetilde{c}$, gives a commutative diagram

$$\begin{array}{ccc} \Lambda & \xrightarrow{\widetilde{c}} & \mathrm{Ch}(\mathrm{Gr}\,\Lambda) \\ {\scriptstyle \widetilde{c}_0}\downarrow & \nearrow & \\ \mathrm{Ch}(\Omega) & & \end{array}$$

By Proposition 6.11, the homomorphism $\Omega \to \mathrm{Gr}\,\Lambda$ is an isomorphism if and only if the homomorphism

$$\mathrm{Ch}(\Omega) \longrightarrow \mathrm{Ch}(\mathrm{Gr}\,\Lambda)$$

is one. Since it is visibly surjective, the latter is also surjective; it remains to show that $\mathrm{Ch}(\Omega) \to \mathrm{Ch}(\mathrm{Gr}\,\Lambda)$ is injective. By functoriality of Ch, one obtains the diagram

$$\begin{array}{ccc} \Lambda & \xrightarrow{\widetilde{c}_0} & \mathrm{Ch}(\Omega) \\ {\scriptstyle \widetilde{c}}\downarrow & & \downarrow{\scriptstyle \widetilde{c}} \\ \mathrm{Ch}(\mathrm{Gr}\,\Lambda) & \xrightarrow[\mathrm{Ch}(\widetilde{c}_0)]{} & \mathrm{Ch}(\mathrm{Gr}_\Lambda(\mathrm{Ch}(\Omega))). \end{array}$$

Since Ω has bounded degrees, the right vertical arrow is an isomorphism by (6.12). Using 6.11, one therefore obtains a morphism

$$\mathrm{Gr}\,\Lambda \longrightarrow \Omega$$

whose two composites with $\Omega \to \mathrm{Gr}\,\Lambda$ are the identity, by the universal property of Ω.

7. Appendix: the Adams operations ψ^k

We follow here a presentation due to J.-P. Serre.

7.1. Let K be a pre-λ-ring. For $x \in K$, write

$$\frac{d}{dt}(\lambda_t(x))$$

for the derivative with respect to t of $\lambda_t(x)$. Define elements of K, denoted $\psi^k(x)$, by putting

$$\frac{d}{dt}(\lambda_t(x))/\lambda_t(x) = \sum_{k=1}^{\infty}(-1)^{k-1}\psi^k(x)t^{k-1}. \tag{7.1.1}$$

The maps $\psi^k : K \to K$ are additive. Indeed,

$$\begin{aligned} \frac{d}{dt}(\lambda_t(x+y))/\lambda_t(x+y) &= \frac{d}{dt}(\lambda_t(x)\lambda_t(y))/\lambda_t(x)\lambda_t(y) \\ &= \frac{d}{dt}(\lambda_t(x))/\lambda_t(x) + \frac{d}{dt}(\lambda_t(y))/\lambda_t(y), \end{aligned}$$

and therefore, for every k,

$$\psi^k(x+y) = \psi^k(x) + \psi^k(y).$$

By (7.1.1), the ψ^k are isobaric polynomials of weight k in the λ^i, $i = 1, \ldots, k$. For example,

$$\psi^1(x) = \lambda^1(x) = x, \qquad \psi^2(x) = x^2 - 2\lambda^2(x).$$

7.2. Let K be a ring of characteristic zero. Suppose given additive maps $\psi^k : K \to K$ such that $\psi^1 = \mathrm{Id}_K$. Define a pre-λ-structure on K by

$$\lambda_t(x) = \exp\left(\sum_{k=1}^{\infty}(-1)^{k-1}\psi^k(x)t^k/k\right). \tag{7.2.1}$$

Multiplicativity follows from the additivity of the ψ^k. Thus there is an equivalence between giving a pre-λ-structure on K and giving the corresponding operations ψ^k.

7.3. It is clear from formula (7.1.1) that the ψ^k commute with λ-homomorphisms. If K, K' are pre-λ-rings of characteristic zero, it is necessary and sufficient for a homomorphism $f : K \to K'$ to be a λ-homomorphism that it commute with the ψ^k. This follows from 7.2, since the λ^i are expressed as polynomials in the ψ^k.

Examples 7.4. i) For $K = \mathbb{Z}$, with its λ-ring structure, one has

$$\frac{d}{dt}(\lambda_t(n))/\lambda_t(n) = n(1+t)^{n-1}/(1+t)^n = n\sum_{k=1}^{\infty}(-1)^{k-1}t^{k-1}.$$

Consequently the ψ^k are all equal to the identity map of $\mathbb{Z}$.

ii) Work in the category $\mathscr{C}_0$ of $\mathbb{Z}$-algebras (1.8). By 7.3, the operations ψ^k define additive endomorphisms of the functor G on λ-rings. By 1.10 they are characterized by their value on $1 + Xt$. One has

$$\frac{d}{dt}(\lambda_u(1+Xt))/\lambda_u(1+Xt) = \frac{1+Xt}{1+\{1+Xt\}u} = \sum_{k=1}^{\infty}(-1)^{k-1}\{1+Xt\}^{\circ k}u^{k-1}.$$

Thus

$$\psi^k(1+Xt) = 1 + X^k t. \tag{7.4.1}$$

Proposition 7.5. i) If K is a λ-ring, the operations ψ^k satisfy the identities

$$\psi^k(1) = 1, \qquad \psi^k(xy) = \psi^k(x)\psi^k(y), \qquad \psi^k \circ \psi^{k'} = \psi^{kk'}. \tag{7.5.1}$$

ii) Conversely, if the ψ^k satisfy these identities and if K is of characteristic zero, then K is a λ-ring.

For (i), if K is a λ-ring, $\lambda_t(1) = 1 + t$, hence

$$\frac{d}{dt}(\lambda_t(1))/\lambda_t(1) = \frac{1}{1+t} = \sum_{k=1}^{\infty}(-1)^{k-1}t^{k-1},$$

and therefore $\psi^k(1) = 1$.

To prove the second relation of (7.5.1), consider the diagram

$$\begin{array}{ccccc} K \times K & \xrightarrow{\lambda_t \times \lambda_t} & \widehat{G}(K) \times \widehat{G}(K) & \xrightarrow{g^k \times g^k} & K \times K \\ \downarrow & & \downarrow \circ & & \downarrow \\ K & \xrightarrow[\lambda_t]{} & \widehat{G}(K) & \xrightarrow[g^k]{} & K, \end{array} \tag{7.5.2}$$

where the vertical arrows are defined by multiplication, and the maps g^k as follows: the logarithmic derivative is a group homomorphism from $G(K)$ to $K[[t]]$, and the map which to

a series assigns its $(k-1)$-st coefficient, multiplied by $(-1)^{k-1}$, is an additive homomorphism from $K[[t]]$ to K; g^k is their composite. Clearly $g^k \circ \lambda_t = \psi^k$ by definition (7.1.1).

The second of formulas (7.5.1) therefore expresses the commutativity of the diagram just written. If K is a λ-ring, the left square is commutative, and it is enough to verify the commutativity of the right square. This is a diagram of functor homomorphisms on $\mathscr{C}_0$, with source $\widehat{G} \times \widehat{G}$. By 1.10 it is enough to verify commutativity on $(1+Xt, 1+Yt)$. Then

$$g^k(1+Xt) = X^k, \qquad g^k(1+Yt) = Y^k,$$

and

$$g^k((1+Xt) \circ (1+Yt)) = g^k(1+XYt) = (XY)^k = g^k(1+Xt)g^k(1+Yt),$$

which gives the result.

To prove the last relation, first observe that the diagram

$$\begin{array}{ccc} \widehat{G}_t(K) & \xrightarrow{\lambda_u} & \widehat{G}_u\widehat{G}_t(K) \\ {\scriptstyle g^k}\downarrow & & \downarrow{\scriptstyle g_u^k} \\ K & \xrightarrow[\lambda_u]{} & \widehat{G}^u(K) \end{array} \tag{7.5.3}$$

is commutative. As above, it is enough to see this for $1+Xt$, and one has

$$g_u^{k'}\lambda_u(1+Xt) = g_u^{k'}(1+\{1+Xt\}u) = (1+Xt)^{\circ k'} = 1+X^{k'}t,$$

and then

$$g^k(1+X^{k'}t) = X^{kk'} = g^k(1+Xt).$$

Consequently

$$\psi^k \circ \psi^{k'} = g^k \circ g_u^{k'} \circ \lambda_u \circ \lambda_t = g^k \circ \lambda_t \circ \psi^{k'}.$$

Moreover

$$\psi^k \circ \psi^{k'} = g^k \circ \lambda_t \circ \psi^{k'} = \psi^k \circ \lambda_t \circ \psi^{k'}.$$

If K is a λ-ring, the diagram

$$\begin{array}{ccc} K & \xrightarrow{\lambda_t} & \widehat{G}(K) \\ {\scriptstyle \psi^{k'}}\downarrow & & \downarrow{\scriptstyle \psi^{k'}} \\ K & \xrightarrow[\lambda_t]{} & \widehat{G}(K) \end{array} \tag{7.5.4}$$

is commutative by 7.3, since λ_t is a λ-homomorphism. The desired relations follow at once.

For (ii), if K is of characteristic zero, the logarithmic derivative is an isomorphism from $\widehat{G}(K)$ onto $K[[t]]$, since one can integrate. Therefore two elements of $\widehat{G}(K)$ are equal if and only if, for every k, they have the same image by g^k.

To show that λ_t is a ring homomorphism, it is enough to show that the left square in (7.5.2) is commutative. By the preceding remark, it is enough to show that, for every k, diagram (7.5.2) is commutative; the right square always is. But this is exactly the relation

$$\psi^k(xy) = \psi^k(x)\psi^k(y).$$

To show that λ_t is a λ-homomorphism, it is enough, by 7.3, to show that diagram (7.5.4) is commutative for every k'. By the preceding remark, this is equivalent to showing, for all k, k', that

$$g^k \circ \psi^{k'} \circ \lambda_t = g^k \circ \lambda_t \circ \psi^{k'},$$

that is, the relations $\psi^{kk'} = \psi^k \circ \psi^{k'}$. Finally, the relation $\lambda_t(1) = 1+t$ is obtained by integration from the relations $\psi^k(1) = 1$.

Exposé VI. The $K^\bullet$ of a projective bundle: computations and consequences

Pierre Berthelot

1. Computation of $K^\bullet$ of a projective bundle: the case of locally free sheaves of finite type

In this section $K^\bullet(X)$ denotes the Grothendieck group of locally free sheaves of finite type on a scheme X. The aim is to prove the following structure theorem.

Theorem 1.1. Let S be a quasi-compact scheme, let E be a locally free $\mathcal{O}_S$-module of rank $r+1$, and let

$$X = \mathbf{P}(E)$$

be the associated projective bundle. The structural morphism $f : X \to S$ gives $K^\bullet(X)$ the structure of a $K^\bullet(S)$-algebra. If $\xi \in K^\bullet(X)$ denotes the class of $\mathcal{O}_X(1)$, then $K^\bullet(X)$ is a free $K^\bullet(S)$-module with basis

$$1, \xi, \ldots, \xi^r.$$

1.2. Plan of the proof

The proof is divided into three parts.

First, one proves that the powers of ξ generate $K^\bullet(X)$ as a $K^\bullet(S)$-module. For this it is enough to establish the following facts. If F is locally free of finite type on X, one can find a graded $\mathrm{Sym}(E)$-module M, of finite presentation and flat over $\mathcal{O}_S$, such that $F = \mathrm{Proj}_0(M)$. Such an M admits a finite graded resolution

$$0 \longrightarrow L_{r+1} \longrightarrow \cdots \longrightarrow L_0 \longrightarrow M \longrightarrow 0$$

by graded $\mathrm{Sym}(E)$-modules locally free of finite type. Finally, each L_i has a finite filtration whose quotients are of the form

$$N \otimes_{\mathcal{O}_S} \mathrm{Sym}(E)(n),$$

with N locally free of finite type on S. Applying Proj_0 then gives the required generation by the powers of ξ.

Second, one proves that $1, \xi, \ldots, \xi^{r+1}$ are linearly dependent over $K^\bullet(S)$. This is obtained from the canonical epimorphism $f^*E \to \mathcal{O}_X(1)$.

Third, one proves that $1, \xi, \ldots, \xi^r$ are linearly independent over $K^\bullet(S)$.

Let S be a scheme, let $B = \bigoplus_{n\geq 0} B_n$ be a graded $\mathcal{O}_S$-algebra, and let M be a graded B-module. If N is a graded B-module, $N(n)$ denotes the graded module defined by

$$N(n)_k = N_{n+k}.$$

A graded B-module is said to be free, respectively locally free, respectively locally free of finite type, if locally on S it is a direct sum, respectively locally a direct sum, respectively locally a finite direct sum, of modules $B(n)$. It is said to be of finite presentation if, locally on S, it admits a presentation by free graded modules of finite type.

For every integer n there is a canonical homomorphism of graded B-modules

$$M_n \otimes_{\mathcal{O}_S} B(-n) \longrightarrow M, \tag{1.2.1}$$

defined by $x \otimes a \mapsto ax$. A free graded module of finite type admits a decomposition

$$M \simeq \bigoplus_{n=n_0}^{n_1} B(-n)^{k_n}. \tag{1.2.2}$$

Proposition 1.2. The integers k_n occurring in a decomposition (1.2.2) are independent of the chosen decomposition.

Indeed, after restricting to an open set where $B_0 = \mathcal{O}_S$, one compares the first non-zero homogeneous component. This determines k_{n_0}; passing to the quotient and arguing by induction gives all the k_n.

Proposition 1.3. Let S be quasi-compact, let E be a locally free $\mathcal{O}_S$-module of finite type, let $X = \mathbf{P}(E)$, and let F be an $\mathcal{O}_X$-module of finite presentation which is flat over S. Then there exists an integer n_0 such that, for all $n \geq n_0$,

(i) $R^i f_*(F(n)) = 0 \quad (i \geq 1)$,

(ii) $f_*(F(n))$ is locally free of finite type on S,

(iii) $M = \bigoplus_{n \geq n_0} f_*(F(n))$ is a graded $\mathrm{Sym}(E)$-module of finite presentation.

The statement is local on S. Since S is quasi-compact, one is reduced to the affine case. If S is noetherian, (i) is Serre's theorem, (ii) follows from EGA III, 7.9.10, and (iii) from the usual comparison between a coherent sheaf on a projective bundle and its associated graded module.

In the general affine case one uses passage to the limit. Write $S = \mathrm{Spec}(A)$ as a filtered projective limit of noetherian affine schemes $S_\lambda = \mathrm{Spec}(A_\lambda)$, with affine transition morphisms. The locally free module E, the scheme X, and the sheaf F descend, after increasing λ, to corresponding data $E_\lambda, X_\lambda, F_\lambda$, with F_λ flat over S_λ. The noetherian case applies to F_λ, and the theorem of change of base gives the assertions after pullback to S.

In this reduction one uses the Cartesian square

$$\begin{array}{ccc} X & \xrightarrow{g} & X_0 \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f_0} \\ S & \xrightarrow[g_0]{} & S_0. \end{array}$$

Here S_0 is noetherian, $X_0 = \mathbf{P}(E_0)$, and $F = g^*(F_0)$. The previous paragraph proves the assertion for F_0, and EGA III, 7.7.5 and 7.8.5 give the required base-change identifications for F.

Corollary 1.4. Under the hypotheses of Proposition 1.3 there exists a graded $\mathrm{Sym}(E)$-module M, of finite presentation and flat over $\mathcal{O}_S$, such that

$$F = \mathrm{Proj}_0(M).$$

Choose an integer n_0 for which the properties of Proposition 1.3 hold. For

$$M = \bigoplus_{n \geq n_0} f_*(F(n)),$$

we have seen that M is of finite presentation; it is flat over S, since the $f_*(F(n))$, for $n \geq n_0$, are locally free on S. Moreover, $F = \mathrm{Proj}_0(M)$ by EGA II 3.4. We now turn to part b) of the proof.

Lemma 1.5.1. Let A be a ring, let B be a positively graded A-algebra with $B_0 = A$, and let M be a graded B-module. Suppose that M, regarded as an ungraded B-module, is projective of finite type. Let $\widetilde{B}$ be the sheaf of algebras on $\mathrm{Spec}(A)$ defined by B, and let $\widetilde{M}$ be the associated graded $\widetilde{B}$-module. Then, locally on $\mathrm{Spec}(A)$, $\widetilde{M}$ is free of finite type over $\widetilde{B}$ as a graded module (1.2).

Indeed, since M is of finite type, its degrees are bounded below. Further, $M \otimes_B A$ is projective of finite type over A, and therefore has only finitely many non-zero homogeneous components, each projective of finite type over A. After localizing on $\mathrm{Spec}(A)$, one may thus suppose that $M \otimes_B A$ is free of finite type over A. Finally, projectivity of M gives

$$\mathrm{Tor}_1^B(M, A) = 0.$$

These properties imply that M is free of finite type over B as a graded module (Bourbaki, *Algèbre*, ch. II, § 11, prop. 7), and hence $\widetilde{M}$ is free of finite type over $\widetilde{B}$, as required.

Lemma 1.5.2. Let A be a ring, let B be an A-algebra of finite presentation, and let M be a B-module of finite presentation. Suppose that B and M are flat over A, and that, for every residue field k of A, the $B \otimes_A k$-module $M \otimes_A k$ has projective dimension at most n (as is the case if $B = A[t_0, \ldots, t_r]$). Then M has a resolution of length n by projective B-modules of finite type:

$$0 \longrightarrow L_n \longrightarrow \cdots \longrightarrow L_0 \longrightarrow M \longrightarrow 0.$$

This is the local criterion of EGA IV, 12.3.2.

Proposition 1.6. Let S be quasi-compact, let E be locally free of rank $r+1$, let $B = \mathrm{Sym}(E)$ with its usual grading, and let M be a graded B-module of finite presentation, flat over S. Then M admits a graded resolution

$$0 \longrightarrow L_{r+1} \longrightarrow \cdots \longrightarrow L_0 \longrightarrow M \longrightarrow 0,$$

where the L_i are graded B-modules locally free of finite type.

First, M admits a graded epimorphism $L \to M$ with L locally free of finite type: choose an integer N such that M is generated in degrees $\leq N$, and take

$$L = \bigoplus_{i \leq N} M_i \otimes_{\mathcal{O}_S} B(-i),$$

with the morphism (1.2.1). Repeating the construction for successive kernels gives a global graded resolution. After $r+1$ steps, Lemma 1.5.2 shows locally on affine opens that the final kernel is projective over B, and Lemma 1.5.1 then shows that it is locally free as a graded B-module; truncation gives the asserted resolution.

Proposition 1.7. Let S be quasi-compact, let E be locally free of finite type, let $B = \mathrm{Sym}(E)$, and let L be a graded B-module locally free of finite type. Then L admits a finite decreasing filtration by graded submodules $L^{(m)}$ such that

(i) $L^{(m)} = L$ for $m \leq m_0$,
(ii) $L^{(m)} = 0$ for $m \geq m_1$,
(iii) $\mathrm{gr}^m L \simeq N_m \otimes_{\mathcal{O}_S} B(m)$,

where N_m is locally free of finite type on S.

The question is local on S. Since S is quasi-compact, the degrees of homogeneous bases that occur locally lie between two fixed integers. One argues by induction on the length of this interval. The first step is the canonical map from the lowest non-zero homogeneous component,

$$L_{n_0} \otimes_{\mathcal{O}_S} B(-n_0) \longrightarrow L,$$

which locally identifies the corresponding direct summand. The quotient has local homogeneous bases in higher degrees, and induction applies.

1.8. Generation by the powers of ξ

Let F be locally free of finite type on X. By Corollary 1.4 and Proposition 1.6, F comes from a graded module M admitting a finite graded resolution by L_i's. Applying Proj_0 gives an exact sequence of locally free sheaves on X, and therefore in $K^\bullet(X)$

$$\mathrm{cl}(F) = \sum_i (-1)^i \,\mathrm{cl}(\mathrm{Proj}_0(L_i)).$$

Using the filtration of Proposition 1.7, each term is a sum of classes

$$\mathrm{cl}\big(f^* N_{ij}(j)\big) = f^* \,\mathrm{cl}(N_{ij})\, \xi^j.$$

Thus $K^\bullet(X)$ is generated as a $K^\bullet(S)$-module by the powers of ξ.

1.9. The relation

For linear dependence, use the canonical epimorphism $f^*E \to \mathcal{O}_X(1)$. Its kernel is locally free of rank r. Hence

$$\lambda^{r+1}(f^*E - \xi) = 0.$$

Since $\lambda_t(-\xi) = 1/(1+\xi t)$, one obtains the relation

$$\sum_{i=0}^{r+1} (-1)^i \,\lambda^i(E)\, \xi^{r+1-i} = 0, \tag{1.9.1}$$

equivalently the characteristic equation of ξ associated with the locally free module E.

1.10–1.11. Linear independence

The proof of the linear-independence assertion is due to J.-P. Jouanolou.

Lemma 1.10. With the hypotheses of Theorem 1.1, let F and G be locally free sheaves of finite type on X, and suppose that they have the same class in $K^\bullet(X)$. Then there is an integer n_0 such that, for all $n \geq n_0$,

(i) $f_*(F(n))$ and $f_*(G(n))$ are locally free of finite type on S,
(ii) $\mathrm{cl}\, f_*(F(n)) = \mathrm{cl}\, f_*(G(n))$ in $K^\bullet(S)$.

An equality of classes in $K^\bullet(X)$ is a finite integral combination of relations coming from short exact sequences of locally free sheaves. Twisting by $\mathcal{O}_X(n)$ and applying f_*, for n large enough all higher direct images vanish and all direct images are locally free of finite type; the same relations then hold in $K^\bullet(S)$.

Suppose that

$$f^*(x_0) + f^*(x_1)\xi + \cdots + f^*(x_r)\xi^r = 0. \tag{1.11.1}$$

Writing each x_i as a difference of classes of locally free sheaves and adding suitable summands, (1.11.1) is converted into an equality $\mathrm{cl}(F) = \mathrm{cl}(G)$ for locally free sheaves of finite type on X. By Lemma 1.10, for all sufficiently large n one has

$$\sum_{i=0}^{r} x_i\, \sigma_{n+i}(E) = 0 \quad \text{in } K^\bullet(S), \tag{1.11.2}$$

where $\sigma_p(E)$ denotes the class of $\mathrm{Sym}^p(E)$, and $\sigma_p(E) = 0$ for $p < 0$.

The Koszul complex of the symmetric algebra gives, for $p \geq 1$,

$$\sum_{i=0}^{r+1} (-1)^i \lambda^i(E)\, \sigma_{p-i}(E) = 0. \tag{1.11.3}$$

Using this relation, one descends by induction from large n in (1.11.2). It follows that (1.11.2) holds for all $n \geq -r$. Taking $n = -r$ gives $x_r = 0$; repeating the argument gives successively all $x_i = 0$. This proves the linear independence and hence Theorem 1.1.

Remark 1.12. Let

$$\sigma_t(E) = \sum_{i \geq 0} \sigma_i(E) t^i.$$

The relation (1.11.3) is equivalent to

$$\lambda_t(E)\, \sigma_{-t}(E) = 1.$$

It follows in particular that σ_t is additive and extends to a homomorphism

$$K^\bullet(S) \longrightarrow 1 + K^\bullet(S)[[t]]_+.$$

Remark 1.13. Any sequence of $r+1$ consecutive powers of ξ is a basis of $K^\bullet(X)$ over $K^\bullet(S)$. If

$$x = 1 - \xi^{-1}$$

is the class of a hyperplane section, then $1, x, \ldots, x^r$ is also a basis. The dependence relation becomes

$$\sum_{k=0}^{r+1} \lambda^{r+1-k}(\check{E} - r - 1)\, x^k = 0. \tag{1.13.1}$$

For $E = \mathcal{O}_S^{r+1}$, so that $X = \mathbf{P}_S^r$, this reduces to

$$x^{r+1} = 0.$$

Using relative schemes in Hakim's sense, Theorem 1.1 also makes sense when S is a locally ringed topos; if the final object of the topos is quasi-compact, the proof transports without essential change.

2. Computation of $K^\bullet$ of a projective bundle: the case of perfect complexes

The present section will not be used in the rest of the Seminar. In this section the notation $K^\bullet(X)$ denotes the Grothendieck group of perfect complexes on X (IV 2.2). We propose to prove the following theorem, analogous to 1.1:

Theorem 2.1. Let S be quasi-compact, let E be a locally free $\mathcal{O}_S$-module of rank $r+1$, let $X = \mathbf{P}(E)$ be the associated projective bundle; let ξ be the class in $K^\bullet(X)$ of the complex equal to $\mathcal{O}_X(1)$ in degree zero, and zero in the other degrees. Then $K^\bullet(X)$, endowed with its natural $K^\bullet(S)$-algebra structure, is a free $K^\bullet(S)$-module with basis

$$1, \xi, \ldots, \xi^r.$$

2.2. Notation

Fix the notation: B will denote the symmetric algebra of E; write $\mathcal{A}$ for the category of $\mathcal{O}_X$-modules, $\mathcal{G}$ for the category of graded B-modules with graded morphisms as morphisms, $\mathcal{G}_0$ for the full subcategory of $\mathcal{G}$ whose objects are the B-modules locally free of finite type as graded B-modules, and $\mathcal{G}'$ for the category of $\mathcal{O}_S$-modules. For every n, and every complex $L^\bullet$ of $D^+(\mathcal{A})$, we shall write $L^\bullet(n)$ for the complex

$$L^\bullet(n) = L^\bullet \otimes_{\mathcal{O}_X} \mathcal{O}_X(n).$$

2.3. The functor Proj_0

We shall need to apply the functor Proj_0 to arbitrary graded B-modules, and not only to quasi-coherent graded B-modules as in the construction of EGA II 3.2. We shall therefore indicate briefly how this construction can be made in the general case.

2.3.1. First let S be a scheme, let A be a quasi-coherent $\mathcal{O}_S$-algebra, let $Y = \mathrm{Spec}(A)$, and let $f : Y \to S$ be the structural morphism. From the isomorphism

$$A \simeq f_*\mathcal{O}_Y$$

one obtains a canonical homomorphism

$$f^{-1}(A) \longrightarrow \mathcal{O}_Y, \tag{2.3.1.1}$$

where f^{-1} denotes inverse image in the sense of sheaves of sets; in other words, one has a morphism of ringed spaces

$$\bar{f} : (Y, \mathcal{O}_Y) \longrightarrow (S, A). \tag{2.3.1.2}$$

It gives an inverse-image functor $\bar{f}^*$ from the category of A-modules to the category of $\mathcal{O}_Y$-modules, left adjoint to the direct-image functor $\bar{f}_*$ from the category of $\mathcal{O}_Y$-modules to the category of $f_*(\mathcal{O}_Y)$-modules. Thus

$$\bar{f}^*(M) = f^{-1}(M) \otimes_{f^{-1}A} \mathcal{O}_Y \tag{2.3.1.3}$$

for every A-module M.

Since the homomorphism (2.3.1.1) is flat (in each fiber it corresponds to a localization), the functor $\bar{f}^*$ just defined is exact (cf. [4], p. 164). If M is a quasi-coherent A-module, this construction gives the module $\widetilde{M}$ defined in EGA II 1.4.3. Indeed, the isomorphism

$$M \simeq f_*(\widetilde{M}) = \bar{f}_*(\widetilde{M})$$

gives, by adjunction, a homomorphism

$$\bar{f}^*(M) \longrightarrow \widetilde{M}$$

and one checks immediately on each fiber that it is an isomorphism.

2.3.2. Now let B be a quasi-coherent graded $\mathcal{O}_S$-algebra, let M be a graded B-module, and let $X = \mathrm{Proj}(B)$. For every affine open U of S, and every section s of B over U, homogeneous of degree $d > 0$, write $M_{(s),U}$ for the homogeneous component of degree 0 of the module of fractions M_s; thus

$$M_{(s),U} = \big((M|_U) \otimes_{B|_U} (B|_U)_s\big)_0.$$

If V is an affine open of U, then $M_{(s),V}$ is the restriction to V of $M_{(s),U}$.

Consider the base of opens of X formed by the affine opens

$$D_+(U,s) \simeq \mathrm{Spec}\big((B|_U)_{(s)}\big)$$

Write f for the structural morphism $X \to S$, and $f_{U,s}$ for the affine morphism

$$f_{U,s} : D_+(U,s) \longrightarrow U.$$

Put

$$\mathrm{Proj}_0(M)_{U,s} = \bar{f}^*_{U,s}(M_{(s),U}).$$

With the notation of 2.3.1, we shall show that the $\mathrm{Proj}_0(M)_{U,s}$ glue as U and s vary, thereby defining an $\mathcal{O}_X$-module denoted $\mathrm{Proj}_0(M)$. The gluing for variable U and fixed s being evident, one is reduced (cf. EGA II 2.5.2) to showing that, if t is a section of B on U, homogeneous of degree $e > 0$, then the restriction of $\mathrm{Proj}_0(M)_{U,s}$ to $D_+(U,st)$ is canonically isomorphic to $\mathrm{Proj}_0(M)_{U,st}$. Consider

$$\begin{array}{ccc} D_+(st) & \xrightarrow{\ i\ } & D_+(s) \\ & \searrow^{f_{U,st}} & \downarrow{\scriptstyle f_{U,s}} \\ & & U \end{array}$$

It is a matter of showing that the modules

$$i^*\bar{f}^*_{U,s}(M_{(s),U}) \quad \text{and} \quad \bar{f}^*_{U,st}(M_{(st),U})$$

are canonically isomorphic. On the one hand, one has the canonical isomorphisms

$$\begin{aligned} i^*\bar{f}^*_{U,s}(M_{(s),U}) &\simeq i^*\Big(f^{-1}_{U,s}(M_{(s),U}) \otimes_{f^{-1}_{U,s}((B|_U)_{(s)})} \mathcal{O}_{D_+(s)}\Big) \\ &\simeq i^{-1}\Big(f^{-1}_{U,s}(M_{(s),U}) \otimes_{f^{-1}_{U,s}((B|_U)_{(s)})} \mathcal{O}_{D_+(s)}\Big) \otimes_{i^{-1}(\mathcal{O}_{D_+(s)})} \mathcal{O}_{D_+(st)} \\ &\simeq f^{-1}_{U,st}(M_{(s),U}) \otimes_{f^{-1}_{U,st}((B|_U)_{(s)})} \mathcal{O}_{D_+(st)}. \end{aligned}$$

On the other hand,

$$\bar{f}^*_{U,st}(M_{(st),U}) \simeq f^{-1}_{U,st}(M_{(st),U}) \otimes_{f^{-1}_{U,st}((B|_U)_{(st)})} \mathcal{O}_{D_+(st)}.$$

Finally, it follows from EGA II 2.2.2, translated into sheaf language, that one has the canonical isomorphisms

$$M_{(st),U} \simeq (M_{(s),U})_{t^d/s^e} \simeq M_{(s),U} \otimes_{(B|_U)_{(s)}} (B|_U)_{(st)},$$

and hence the desired isomorphism.

It is clear that, if M is quasi-coherent, the module $\mathrm{Proj}_0(M)$ thus constructed is indeed the one defined in EGA II.

2.3.3. It follows from 2.3.1 and 2.3.2 that the functor Proj_0 is exact. Returning to the notation of 2.2, by passage to derived categories one therefore obtains a functor, still denoted Proj_0:

$$\mathrm{Proj}_0 : D^+(\mathcal{G}) \longrightarrow D^+(\mathcal{A}).$$

It is also clear from the preceding constructions that the functor Proj_0, on the category of graded B-modules, is compatible with tensor product; the same remains true of the functor obtained on the derived categories.

2.4. The functor F_k

For an $\mathcal{O}_X$-module L and an integer k, set

$$F_k(L) = \bigoplus_{n \geq k} f_*(L(n)). \tag{2.4.1}$$

The functor F_k is left exact and therefore has a right derived functor

$$RF_k : D^+(\mathcal{A}) \longrightarrow D^+(\mathcal{G}). \tag{2.4.2}$$

If L is locally free of finite type, then for k sufficiently large it is F_k-acyclic, by the vanishing theorem used above in 1.3.

For every k there is a functorial morphism

$$\beta : \mathrm{Proj}_0(F_k(F)) \longrightarrow F, \tag{2.5.1}$$

constructed on each $D_+(U, s)$ by the usual localization formula: a fraction represented by a homogeneous section of sufficiently high degree is sent to the corresponding local section of F. In the quasi-coherent case this is the canonical morphism of EGA. Passing to derived categories gives

$$\mathrm{Proj}_0 \circ RF_k \longrightarrow \mathrm{id}_{D^+(\mathcal{A})}\,. \tag{2.5.2}$$

Proposition 2.6. Let S be quasi-compact, let E be locally free of finite type, let $X = \mathbf{P}(E)$, and let $L^\bullet$ be a perfect complex on X. Then, for k sufficiently large,

(i) $RF_k(L^\bullet)$ is $\mathcal{G}_0$-perfect,

(ii) $\mathrm{Proj}_0\, RF_k(L^\bullet) \longrightarrow L^\bullet$ is an isomorphism in $D^+(\mathcal{A})$.

The assertion is local on S. One may therefore assume S affine. Since $\mathcal{O}_X(1)$ is ample, the perfect complex $L^\bullet$ is locally, and then globally after refining, represented by a bounded complex whose terms are locally free of finite type. For k sufficiently large all those finitely many terms are F_k-acyclic, and the graded modules $F_k(L^i)$ are $\mathcal{G}_0$-perfect. This gives (i), and the morphism (2.5.2) is then an isomorphism term by term, giving (ii).

2.7. Decomposition of a $\mathcal{G}_0$-perfect complex

On $\mathcal{G}$, the functor which associates to a graded B-module its n-th homogeneous component is exact with values in $\mathcal{G}'$; it defines a functor

$$\mathrm{Comp}_n : D^+(\mathcal{G}) \longrightarrow D^+(\mathcal{G}'). \tag{2.7.1}$$

The homomorphism (1.2.1) gives a morphism of functors

$$\mathrm{Comp}_n \otimes_{\mathcal{O}_S} B(-n) \longrightarrow \mathrm{id}_{D^+(\mathcal{G})}\,. \tag{2.7.2}$$

Let $M^\bullet$ be a $\mathcal{G}_0$-perfect complex. We shall show that there exists a finite sequence of distinguished triangles

$$\begin{array}{ccc} & P_1^\bullet & \\ \swarrow & & \nwarrow \\ N_1^\bullet & \longrightarrow & M^\bullet, \end{array} \qquad \begin{array}{ccc} & P_2^\bullet & \\ \swarrow & & \nwarrow \\ N_2^\bullet & \longrightarrow & P_1^\bullet, \end{array} \quad \cdots, \quad \begin{array}{ccc} & P_k^\bullet & \\ \swarrow & & \nwarrow \\ N_k^\bullet & \longrightarrow & P_{k-1}^\bullet, \end{array}$$

where each $P_k^\bullet$ at the last stage is acyclic, the terms $N_i^\bullet$ are of the form

$$N_i^\bullet = K_i^\bullet \otimes_{\mathcal{O}_S} B(d_i),$$

and the $K_i^\bullet$ are perfect complexes on S in the ordinary sense.

Indeed, because $M^\bullet$ is $\mathcal{G}_0$-perfect and S is quasi-compact, there exists a finite covering of S and an integer d_0 such that, on every open of the covering, $M^\bullet$ is represented by a bounded complex of locally free B-modules of finite type, with no homogeneous generators in degrees $< d_0$. Taking d_0 minimal, the morphism (2.7.2) extracts the part of the lowest degree. Its cone has all homogeneous generators in strictly higher degrees. Repeating the process, and using the finiteness of the degree interval from Proposition 1.7, one obtains the desired finite sequence of triangles.

2.8. Proof of Theorem 2.1

Let $L^\bullet$ be a perfect complex on X. For k sufficiently large put

$$M^\bullet = RF_k(L^\bullet).$$

By Proposition 2.6, $M^\bullet$ is $\mathcal{G}_0$-perfect and $\mathrm{Proj}_0(M^\bullet) \simeq L^\bullet$. Applying the decomposition of 2.7 and then Proj_0, one obtains in $K^\bullet(X)$

$$\mathrm{cl}(L^\bullet) = \sum_i \mathrm{cl}(f^* K_i^\bullet(d_i)) = \sum_i f^* \,\mathrm{cl}(K_i^\bullet)\, \xi^{d_i}.$$

Thus the powers of ξ generate $K^\bullet(X)$ as a $K^\bullet(S)$-module.

The dependence relation is the same relation (1.9.1), now interpreted in the Grothendieck group of perfect complexes. For linear independence one uses the $K^\bullet(S)$-linear homomorphism

$$f_* : K^\bullet(X) \longrightarrow K^\bullet(S).$$

For the structure sheaf and negative twists of the projective bundle one has

$$f_*(1) = 1, \qquad f_*(\xi^n) = 0 \quad (-r \le n < 0).$$

Multiplying a relation among $1, \xi, \ldots, \xi^r$ by suitable negative powers of ξ and applying f_* successively gives all its coefficients equal to zero. This completes the proof of Theorem 2.1.

This completes the induction, for if $0 \le s \le r$ and if $x_j = 0$ for $s < j \le r$, then from a relation

$$\sum_{i=0}^{s} f^*(x_i)\xi^i = 0$$

after multiplication by ξ^{r-s} one gets

$$\sum_{i=0}^{s} f^*(x_i)\xi^{i+r-s} = 0,$$

and hence $x_s = 0$ by what precedes.

3. Consequences of the structure theorem for the $K^\bullet$ of a projective bundle

Proposition 3.1. Let S be a quasi-compact scheme, let $E_1, \ldots, E_n$ be $\mathcal{O}_S$-modules locally free of finite type, and let $D(E_i)$ be the flag scheme of E_i. Put

$$X = D(E_1) \times_S \cdots \times_S D(E_n).$$

Then the canonical homomorphism

$$K^\bullet(S) \longrightarrow K^\bullet(X)$$

is injective, where $K^\bullet$ is defined either from $\mathcal{O}_S$-modules locally free of finite type or from perfect complexes.

One verifies this immediately by using the universal property of flag schemes. The scheme X can be constructed as follows: one considers a sequence of S-schemes $X_1, \ldots, X_n$, defined by induction by taking X_k to be the flag scheme of the inverse image of E_k on X_{k-1}; then $X = X_n$. Thus, to prove the proposition, it is enough to prove it when $n = 1$, the general case following by induction. We may therefore suppose that X is the flag scheme of an $\mathcal{O}_S$-module E, locally free of finite type.

The scheme X may then be constructed as follows. Put $E = F_0$, $S = X_0$, and define successively schemes $X_1, \ldots, X_n$ and, for each i, an $\mathcal{O}_{X_i}$-module locally free of finite type F_i, by

$$X_i = \mathbb{P}(F_{i-1}), \qquad F_i = \mathrm{Ker}\big(f_i^*(F_{i-1}) \longrightarrow \mathcal{O}_{X_i}(1)\big),$$

where $f_i : X_i \to X_{i-1}$ is the structural morphism. It follows that it is enough to prove the proposition for a projective bundle. This is precisely the content of 1.1, respectively of 2.1, according to which definition of $K^\bullet$ is being used.

Theorem 3.2. Let S be a quasi-compact scheme. The pre-λ-ring $K^\bullet(S)$, defined from $\mathcal{O}_S$-modules locally free of finite type, is a λ-ring.

The homomorphism

$$\lambda_t : K^\bullet(S) \longrightarrow 1 + K^\bullet(S)[[t]]^+$$

being additive, it is enough, in order to verify that it is a λ-homomorphism, to check the universal relations on elements of the form $\mathrm{cl}(E)$, where E is an $\mathcal{O}_S$-module locally free of finite type. Thus one has to show that for every pair E, F of such modules, with classes again denoted E, F, the relations V 2.4.2 are satisfied:

$$\lambda^i(EF) = P_i(\lambda^1(E), \ldots, \lambda^i(E); \lambda^1(F), \ldots, \lambda^i(F)),$$

$$\lambda^j(\lambda^i(E)) = Q_{i,j}(\lambda^1(E), \ldots, \lambda^{ij}(E)).$$

Since S is quasi-compact, it admits a finite covering by disjoint opens such that on each of them E and F have constant rank. Since the $K^\bullet$ of a finite disjoint union is the product of the corresponding $K^\bullet$'s, it is enough to check the relations on the members of this covering; hence we may suppose that E and F have constant ranks on S.

Put then

$$X = D(E) \times_S D(F).$$

By Proposition 3.1 the λ-homomorphism $K^\bullet(S) \to K^\bullet(X)$ is injective. Consequently, in order to prove the relations V 2.4.2, we may work in $K^\bullet(X)$. But in $K^\bullet(X)$ the elements E and F split as sums of classes of invertible sheaves. By additivity it is therefore enough to prove the same relations for elements ξ, η which are classes of invertible sheaves. Written in the form V 2.4.1, the relations are

$$1 + \xi\eta t = (1 + \xi t) \circ (1 + \eta t), \qquad \lambda_u(1 + \xi t) = 1 + \{1 + \xi t\}u.$$

These are just the relations V 2.3.1 and V 2.3.3 defining the λ-ring structure on $1 + K^\bullet(S)[[t]]^+$.

Let us also record the following more general result.

Theorem 3.3. Let (T, A) be a commutatively ringed topos, and let K be the Grothendieck group of A-modules locally free of bounded rank on T. Then K, endowed with its canonical pre-λ-structure, is a λ-ring.

To prove that K is a λ-ring, it is necessary to prove the relations V 2.4.1; by additivity, it is enough to prove them for classes of A-modules E, F locally free of bounded rank. Since the ranks of E and F are bounded, one may decompose T as a finite disjoint sum of opens over which E and F have constant rank. Using the compatibility of K with finite disjoint sums, and writing the relations V 2.4.1 in the form V 2.4.2, we are reduced to the case of modules of constant rank.

Let E be an A-module locally free of finite rank n. There is a torsor P under $\mathrm{GL}(n, A)$ such that

$$E = P \times_{\mathrm{GL}(n,A)} A^n,$$

where A^n is considered as a $\mathrm{GL}(n, A)$-module by the standard representation. One can then define a λ-homomorphism from the representation ring $R_{\mathbb{Z}}(\mathrm{GL}(n))$ to K by associating to a representation ρ of $\mathrm{GL}(n)$ in a free $\mathbb{Z}$-module of rank p the class of

$$P \times_{\mathrm{GL}(n,A)} A^p.$$

Under this homomorphism, the class of E is the image of the standard representation. Thus any polynomial relation among the $\lambda^i(E)$'s follows from the corresponding relation for the standard representation in $R_{\mathbb{Z}}(\mathrm{GL}(n))$.

Similarly, for two locally free modules E, F of ranks n, p, one uses a torsor under $\mathrm{GL}(n, A) \times \mathrm{GL}(p, A)$, with $\mathrm{GL}(n, A)$ acting through the standard representation and $\mathrm{GL}(p, A)$ through the trivial one on the first factor, and conversely for F. We are reduced to proving that, for every group scheme G over $\operatorname{Spec}\mathbb{Z}$ which is a finite product of linear group schemes, the pre-λ-ring $R_{\mathbb{Z}}(G)$ is a λ-ring. This may be obtained by the explicit computation of $R_{\mathbb{Z}}(G)$ in [5]; alternatively, one can reason as in 3.2, using 1.14.

4. Computation of the $K^\bullet$ of a flag bundle

4.1

Let S be a scheme and let E be an $\mathcal{O}_S$-module locally free of rank n. Let

$$\pi = (p_1, \ldots, p_k), \qquad p_i \geq 1, \qquad \sum_{i=1}^{k} p_i = n.$$

The flag functor of type π of E is the functor on the category of S-schemes, with values in sets, which to an S-scheme $f : X \to S$ associates the set of chains of quotients of f^*E

$$(L_{k-1}, \ldots, L_1),$$

where, for each i, L_i is a quotient of L_{i+1}, locally free of rank $p_1 + \cdots + p_i$. This functor is representable by an S-scheme $D_\pi(E)$, endowed with a canonical sequence of quotients of the inverse image of E, locally free of ranks $p_1, p_1 + p_2, \ldots$. If $\pi = (1, n-1)$, then $D_\pi(E) = \mathbb{P}(E)$; if $\pi = (r, n-r)$, then $D_\pi(E) = G_{r,n}(E)$, the Grassmannian of type $(r, n-r)$ of E. If all p_i's are equal to 1, one obtains the usual flag bundle of E, denoted $D(E)$.

Lemma 4.2. Let S be a scheme, let E be an $\mathcal{O}_S$-module locally free of rank n, and let

$$\pi = (p_1, \ldots, p_i, \ldots, p_k), \qquad p_1 + \cdots + p_k = n.$$

Let $p', p'' \geq 1$ be such that $p' + p'' = p_i$, and put

$$\pi' = (p_1, \ldots, p_{i-1}, p', p'', p_{i+1}, \ldots, p_k), \qquad \pi'' = (p', p'').$$

Let $L_1, \ldots, L_{k-1}$ be the canonical quotients of the inverse image of E on $D_\pi(E)$, and let F be the kernel of $L_i \to L_{i-1}$. Then there is a canonical S-isomorphism

$$D_{\pi'}(E) \simeq D_{\pi''}(F).$$

The proof, immediate from the functorial definition of flag schemes, is left to the reader.

Lemma 4.3. Let A be a commutative ring with unit, let $n > 0$, and let $(c_i)_{1 \leq i \leq n}$ be elements of A. Let C be the A-algebra generated by $\xi_1, \ldots, \xi_n$, subject to the relations

$$\sigma_i(\xi_1, \ldots, \xi_n) = c_i, \qquad i = 1, \ldots, n,$$

where σ_i denotes the elementary symmetric functions. Let $p_1, \ldots, p_k$ be integers ≥ 1 whose sum is n. For $1 \leq j \leq k$ put

$$\xi^{(j)} = (\xi_1^{(j)}, \ldots, \xi_{p_j}^{(j)}), \qquad \xi_i^{(j)} = \xi_{\sum_{\alpha<j} p_\alpha + i}.$$

Put

$$c_i^{(j)} = \sigma_i(\xi_1^{(j)}, \ldots, \xi_{p_j}^{(j)}), \qquad 1 \leq j \leq k, \quad 1 \leq i \leq p_j,$$

and let B be the subalgebra of C generated by the $c_i^{(j)}$'s. Then:

i) The elements

$$(\xi^{(1)})^{\alpha(1)} \cdots (\xi^{(k)})^{\alpha(k)}, \qquad 0 \leq \alpha_i^{(j)} \leq p_j - i,$$

form a basis of C, considered as a B-module.

ii) The generators $c_i^{(j)}$ of the A-algebra B satisfy the n isobaric relations deduced from

$$\sum_{i=1}^{n} c_i = \prod_{j=1}^{k} \left(\sum_{i=1}^{p_j} c_i^{(j)} \right),$$

where c_i and $c_i^{(j)}$ are assigned weight i; these n relations generate the ideal of relations among the $c_i^{(j)}$'s.

Corollary 4.4. The elements of C of the form

$$\xi_1^{\alpha_1} \cdots \xi_{n-1}^{\alpha_{n-1}}, \qquad 0 \leq \alpha_i \leq n - i,$$

form a basis of C as an A-module.

For the proof of the lemma and corollary we refer to [2], Exposé 4, pages 4.19, from which they are borrowed.

4.5

Let S be quasi-compact, let E be an $\mathcal{O}_S$-module locally free of rank n, let $\pi = (p_1, \ldots, p_k)$ be a sequence of integers ≥ 1 with sum n, and put $X = D_\pi(E)$. The scheme X is equipped with canonical quotients L_i. Put $L_0 = 0$, $L_k = f^*E$, where $f : X \to S$ is the structural morphism. For $1 \leq i \leq k$, let F_i be the kernel of $L_i \to L_{i-1}$. Let $K^\bullet(X)$ be the Grothendieck group of

locally free finite-type sheaves on X, respectively of perfect complexes. Denote by F_j the class of F_j, and by $\lambda_i^{(j)}$ the class of $\lambda^i(F_j)$. In the case where $K^\bullet(X)$ is defined by perfect complexes, one gives the same evident meaning to the series $\lambda_t(E)$ and $\lambda_t(F_j)$, where E is the class of E. Finally,

$$\sum_{j=1}^{k} F_j = E.$$

Theorem 4.6. With the hypotheses and notations of 4.5, the $K^\bullet(S)$-algebra $K^\bullet(X)$ is generated by the $\lambda_i^{(j)}$, and the ideal of relations among the $\lambda_i^{(j)}$'s is generated by the relations deduced from

$$\lambda_t(E) = \prod_{j=1}^{k} \lambda_t(F_j).$$

Equivalently, $K^\bullet(X)$ is the $K^\bullet(S)$-λ-algebra generated by $F_1, \ldots, F_k$, subject to the relations

$$\text{(i)} \quad \lambda^p(F_i) = 0 \quad (p > p_i), \qquad \text{(ii)} \quad \sum_i F_i = E.$$

We first treat the case where all p_i's are equal to 1. Then the theorem reads as follows.

Corollary 4.7. Let S be quasi-compact, let E be an $\mathcal{O}_S$-module locally free of rank n, let $X = D(E)$ be the flag bundle of E, and let $\xi_1, \ldots, \xi_n$ be the classes of the invertible sheaves $F_1, \ldots, F_n$. Then $K^\bullet(X)$ is the $K^\bullet(S)$-algebra generated by the ξ_i's, subject to the relations

$$\sigma_i(\xi_1, \ldots, \xi_n) = \lambda^i(E).$$

We argue by induction on n. For $n = 1$ the assertion is trivial. Suppose it known for $n - 1$. Consider $\mathbb{P}(E)$, and on $\mathbb{P}(E)$ the exact sequence

$$0 \longrightarrow F \longrightarrow g^*E \longrightarrow \mathcal{O}_{\mathbb{P}(E)}(1) \longrightarrow 0,$$

where g is the structural morphism of $\mathbb{P}(E)$. By Lemma 4.2, X identifies with the usual flag bundle $D(F)$ over $\mathbb{P}(E)$, and the canonical sheaves correspond under this identification. The diagram

$$\begin{array}{ccc} D(E) = D(F) & \xrightarrow{\ h\ } & \mathbb{P}(E) \\ & \searrow^{f} & \downarrow{\scriptstyle g} \\ & & S \end{array}$$

shows that $K^\bullet(S) \to K^\bullet(X)$ factors through $K^\bullet(\mathbb{P}(E))$. By the induction hypothesis applied to $D(F)$, and by Corollary 4.4, $K^\bullet(X)$ has over $K^\bullet(\mathbb{P}(E))$ a basis formed by

$$\xi_2^{\alpha_2} \cdots \xi_n^{\alpha_{n-1}}, \qquad 0 \le \alpha_i \le n - i.$$

Moreover $K^\bullet(\mathbb{P}(E))$ has over $K^\bullet(S)$ the basis $1, \xi_1, \ldots, \xi_1^{n-1}$. Hence $K^\bullet(X)$ has over $K^\bullet(S)$ the basis

$$\xi_1^{\alpha_1} \cdots \xi_{n-1}^{\alpha_{n-1}}, \qquad 0 \le \alpha_i \le n - i.$$

In addition, the additivity of λ_t gives $\prod_i (1 + \xi_i t) = \lambda_t(E)$, so the displayed relations are satisfied. If C is the $K^\bullet(S)$-algebra generated by ξ_i's and subjected to these relations, then there is a surjective homomorphism $C \to K^\bullet(X)$. By Corollary 4.4 this homomorphism sends a basis of C to a basis of $K^\bullet(X)$, hence it is an isomorphism.

For a general flag bundle of type π, the usual flag bundle $D(E)$ is obtained from $D_\pi(E)$ by constructing successively the flag bundles of the F_j's. It follows that $K^\bullet(D(E))$, considered as a

module over $K^\bullet(X)$, has a basis formed by the elements appearing in 4.3.i), the $\xi_i^{(j)}$'s being the classes of the sheaves analogous to the F_j's in the splitting of the inverse images of the F_j's on $D(E)$. Thus $K^\bullet(X)$ is a subring of $K^\bullet(D(E))$. Moreover, additivity gives

$$\lambda_i^{(j)} = \sigma_i(\xi_1^{(j)}, \ldots, \xi_{p_j}^{(j)}),$$

and therefore $K^\bullet(X)$ contains the sub-$K^\bullet(S)$-algebra of $K^\bullet(D(E))$ generated by the $\lambda_i^{(j)}$'s. If B is this subalgebra, then by 4.3.i) the same family of elements is a basis both for the B-module structure and for the $K^\bullet(X)$-module structure. Hence $K^\bullet(X) = B$, proving generation. The ideal of relations among the $\lambda_i^{(j)}$'s is then given by 4.3.ii), taking into account the structure of $K^\bullet(D(E))$ over $K^\bullet(S)$ determined by 4.7, and the fact that the $\xi_i^{(j)}$'s are precisely the classes involved in the splitting of the inverse image of E on $D(E)$. This proves the first form of 4.6.

For the second form, one observes that the elements F_i of the $K^\bullet(S)$-λ-algebra $K^\bullet(X)$ satisfy (i) and (ii). If A is the $K^\bullet(S)$-λ-algebra generated by elements F_i' satisfying (i) and (ii), there is therefore a $K^\bullet(S)$-λ-homomorphism $A \to K^\bullet(X)$ sending F_i' to F_i. By 4.6 this homomorphism is surjective. Since the λ-ideal generated by (i) and (ii) in $K^\bullet(S)[F_1, \ldots, F_k]$ contains the usual ideal generated by the first form of the relations, the homomorphism is also injective. Thus it is an isomorphism.

Corollary 4.8. With the hypotheses and notations of 4.5, put

$$c_i^{(j)} = \gamma^i(F_j - p_j), \qquad 1 \leq i \leq p_j.$$

Then the $K^\bullet(S)$-algebra $K^\bullet(X)$ is generated by the $c_i^{(j)}$'s, and the ideal of relations among them is generated by the relations deduced from

$$\gamma_t(E - n) = \prod_{j=1}^{k} \gamma_t(F_j - p_j).$$

This is merely another formulation of 4.6. Indeed, the $c_i^{(j)}$'s may be expressed as functions of the $\lambda_i^{(j)}$'s and conversely. Moreover the relation $\lambda_t(E) = \prod \lambda_t(F_j)$ is equivalent to $\gamma_t(E - n) = \prod \gamma_t(F_j - p_j)$.

4.9

Let S be a scheme. Denote by $G_S^{n,r}$ the Grassmannian of type $(n, r-n)$ of $\mathcal{O}_S^r$, with $r \geq n$. For variable r, the $G_S^{n,r}$ form an inductive system, the morphism

$$G_S^{n,r} \longrightarrow G_S^{n,r+1}$$

being defined by considering $\mathcal{O}^r_{G_S^{n,r}}$ as the quotient of $\mathcal{O}^{r+1}_{G_S^{n,r}}$ by the $(r+1)$-st factor. In this system of morphisms the canonical quotients therefore correspond by inverse image. The inductive system so defined will be denoted $G_S^{n,\infty}$.

We define its $K^\bullet$ by the formula

$$K^\bullet(G_S^{n,\infty}) = \varprojlim_r K^\bullet(G_S^{n,r}). \tag{4.9.1}$$

Let F_1, F_2 be the canonical sheaves on $G_S^{n,r}$ (4.5), and F_1, F_2 their classes in $K^\bullet(G_S^{n,r})$. Put

$$c_i = \gamma^i(F_1 - n).$$

When r varies, the c_i correspond under the transition morphisms and consequently define elements, still denoted c_i, of $K^\bullet(G_S^{n,\infty})$.

Proposition 4.10. Let S be a quasi-compact scheme. Then, with the notation of 4.9, one has an isomorphism

$$K^\bullet(G_S^{n,\infty}) \simeq K^\bullet(S)[[c_1, \ldots, c_n]].$$

By 4.8, $K^\bullet(G_S^{n,r})$ is the $K^\bullet(S)$-algebra generated by

$$c_i = \gamma^i(F_1 - n), \quad 1 \leq i \leq n,$$

and by

$$\gamma^j(F_2 - r + n), \quad 1 \leq j \leq r - n,$$

subject to the relations deduced from

$$\gamma_t(F_1 - n) \cdot \gamma_t(F_2 - r + n) = \gamma_t(r - r) = 1,$$

or equivalently

$$\gamma_t(F_2 - r + n) = 1/\gamma_t(F_1 - n).$$

This relation makes it possible to express the $\gamma^j(F_2 - r + n)$ in terms of the c_i, and gives a series of isobaric relations among the c_i (where c_i is assumed to have weight i) by writing that the coefficients of $1/\gamma_t(F_1 - n)$ vanish in degree $> r - n$; moreover, these relations generate the ideal of relations among the c_i. We may therefore write

$$K^\bullet(G_S^{n,r}) = K^\bullet(S)[c_1, \ldots, c_n]/I_r,$$

where I_r is a homogeneous ideal of $K^\bullet(S)[c_1, \ldots, c_n]$, of degree $> r - n$. It then follows from the definition (4.9.1) that $K^\bullet(G_S^{n,\infty})$ is the separated completion of $K^\bullet(S)[c_1, \ldots, c_n]$ for the topology defined by the I_r. This topology is finer than the topology defined by weight; we shall show that it is equivalent to it, which will imply the proposition.

Put $A = K^\bullet(S)[c_1, \ldots, c_n]/I_r$, and let C be the A-algebra generated by generators $x_1, \ldots, x_n$ subject to the relations

$$\sigma_j(x_1, \ldots, x_n) = c_j,$$

where the σ_j denote the elementary symmetric functions. By 4.4, the canonical homomorphism $A \to C$ is injective. We obtain

$$\gamma_t(F_1 - n) = 1 + c_1 t + \cdots + c_n t^n = \prod_{i=1}^{n} (1 + x_i t).$$

Since $1/\gamma_t(F_1 - n)$ is a polynomial, so is $1/(1 + x_i t)$, for every i. Hence the x_i are nilpotent, and there exists an integer N such that every polynomial of degree $> N$ in the x_i, with coefficients in $K^\bullet(S)$, is zero. Consequently every polynomial of A of weight $> N$ is zero, i.e. every polynomial of $K^\bullet(S)[c_1, \ldots, c_n]$ of weight $> N$ belongs to I_r. It follows that the two topologies under consideration are equivalent, completing the proof.

5. Applications to projective bundles; study of f_*

5.1

Let S be quasi-compact, let E be locally free of rank $r + 1$, and put $X = \mathbb{P}(E)$, with structural morphism $f : X \to S$. On X one has the canonical exact sequence

$$0 \longrightarrow F \longrightarrow f^*E \longrightarrow \mathcal{O}_X(1) \longrightarrow 0.$$

Let E, F, ξ denote the corresponding classes in $K^\bullet$, and put $x = \xi - 1$.

5.2

For a locally free sheaf G on X, the higher direct images $R^i f_* G$ need not be locally free of finite type on S. Thus the direct image $f_* : K^\bullet(X) \to K^\bullet(S)$ is not defined here by alternating sums of higher direct images. Theorem 1.1 gives a substitute: every $y \in K^\bullet(X)$ is uniquely expressible in the form

$$y = a_0 + a_1\xi + \cdots + a_r\xi^r, \qquad a_i \in K^\bullet(S),$$

and we put

$$f_*(y) = a_0.$$

This additive homomorphism satisfies the projection formula. Moreover,

$$f_*(1) = 1, \qquad f_*(\xi^n) = 0 \quad (-r \le n < 0), \qquad f_*(\xi^n) = s_n \quad (n \ge 0),$$

where s_n is the n-th complete symmetric function in the roots of E. The last relations follow by induction from the dependence relation and the Koszul relation.

Proposition 5.3. For every $k \ge 0$,

$$\mathrm{Fil}^k K^\bullet(X) = \mathrm{Fil}^k K^\bullet(S) + \mathrm{Fil}^{k-1} K^\bullet(S)x + \cdots + \mathrm{Fil}^{k-r} K^\bullet(S)x^r,$$

as a direct sum of $K^\bullet(S)$-modules, where the filtration is the canonical filtration of augmented λ-rings.

Here x has augmentation zero and

$$\gamma_t(x) = \lambda_{t/(1-t)}(1 - \xi^{-1}) = \frac{1}{1 - xt},$$

so that $\gamma^i(x) = x^i$. The result follows from the computation of the filtration for free λ-rings in V, 4.12 and V, 4.13, together with the relation (1.9.1). Directness follows from the independence of $1, x, \ldots, x^r$.

Corollary 5.4. The filtration induced on $K^\bullet(S)$ by $K^\bullet(X)$ is the original filtration of $K^\bullet(S)$.

Corollary 5.5. If X is a product over S of flag bundles of locally free sheaves, then

$$\mathrm{Gr}\, K^\bullet(S) \longrightarrow \mathrm{Gr}\, K^\bullet(X)$$

is injective.

Corollary 5.6. With the notation of the projective bundle above, $\mathrm{Gr}\, K^\bullet(X)$ is a free $\mathrm{Gr}\, K^\bullet(S)$-module with basis $1, x, \ldots, x^r$, and

$$\mathrm{Gr}^k K^\bullet(X) = \mathrm{Gr}^k K^\bullet(S) \oplus \mathrm{Gr}^{k-1} K^\bullet(S)x \oplus \cdots \oplus \mathrm{Gr}^{k-r} K^\bullet(S)x^r.$$

The elements $1, x, \ldots, x^{r+1}$ satisfy

$$\sum_{i=0}^{r+1} (-1)^i c_i(E) x^{r+1-i} = 0,$$

where $c_i(E)$ is the i-th Chern class of E.

Corollary 5.7. For a flag bundle as in 4.5, the $\mathrm{Gr}\, K^\bullet(S)$-algebra $\mathrm{Gr}\, K^\bullet(X)$ is generated by the classes $\xi_i^{(\alpha)}$ of $\xi_i^{(\alpha)} - 1$, with relations generated by

$$c_t(E) = \prod_{i,\alpha} c_t(\xi_i^{(\alpha)}),$$

where c_t denotes the total Chern class.

Corollary 5.8. For every k,

$$f_*(\mathrm{Fil}^k K^\bullet(X)) \subset \mathrm{Fil}^k K^\bullet(S).$$

This follows immediately from Proposition 5.3 and the projection formula.

Proposition 5.9. With the notation of 5.1, for every $y \in K^\bullet(X)$, one has

$$f_*(\lambda_{-1}(F)y) = 0, \qquad f_*(\gamma^*(F)y) = 0.$$

In particular,

$$f_*(\lambda_{-1}(F)) = 1.$$

If

$$\xi_t : 1 + K^\bullet(X)[[t]]^+ \longrightarrow 1 + K^\bullet(S)[[t]]^+$$

is defined coefficientwise by

$$\xi_t\left(\sum a_i t^i\right) = \sum f_*(a_i)t^i,$$

then, although it is not in general a homomorphism of groups, it satisfies

$$\xi_t(mf^*y) = \xi_t(m)y.$$

Using $E = F + \xi$ and $\lambda_t(E) = \lambda_t(F)(1 + \xi t)$, one obtains the asserted identities.

Proposition 5.10. Let $z \in K^\bullet(X)$. The condition

$$z(1 - \xi) = 0$$

is equivalent to the existence of an element $y \in K^\bullet(S)$ such that

$$\text{(i)} \quad z = y\lambda_{-1}(F), \qquad \text{(ii)} \quad y\lambda_{-1}(E) = 0.$$

Sufficiency follows from

$$\lambda_{-1}(E) = \lambda_{-1}(F)\lambda_{-1}(\xi) = \lambda_{-1}(F)(1 - \xi).$$

Conversely, write $z = \sum_{i=0}^r a_i\xi^i$. Combining the dependence relation among the powers of ξ with $z(1 - \xi) = 0$, and using the independence of $1, \ldots, \xi^r$, expresses z as a multiple of $\lambda_{-1}(F)$. The top relation gives $y\lambda_{-1}(E) = 0$.

Proposition 5.11. Let $z \in \mathrm{Gr}\, K^\bullet(X)$. The condition $zx = 0$ is equivalent to the existence of $y \in \mathrm{Gr}\, K^\bullet(S)$ such that

$$\text{(i)} \quad z = y\, c_{\mathrm{top}}(F), \qquad \text{(ii)} \quad y\, c_{\mathrm{top}}(E) = 0.$$

The proof is the same as that of 5.10, after passing to associated graded rings and using 5.6.

6. Study of the filtration of $K^\bullet(X)$ when X has an ample sheaf

Let X be a scheme possessing an ample sheaf. Then the two definitions of $K^\bullet(X)$, by locally free finite-type sheaves and by perfect complexes, coincide. Let

$$\varepsilon : K^\bullet(X) \longrightarrow H^0(X, \mathbb{Z})$$

be the augmentation.

Proposition 6.1. If X is quasi-compact and has an ample sheaf, then $\mathrm{Fil}^1 K^\bullet(X)$ is a nilideal.

It is enough to show that $E - \varepsilon(E)$ is nilpotent, where E is the class of a locally free sheaf. By decomposing X into finitely many disjoint opens and then passing to the flag bundle of E, one reduces to the case where E is the class of an invertible sheaf. Let L be the class of an ample invertible sheaf. For n sufficiently large, $E^\vee(n)$ is generated by global sections, giving a surjection $(E(-n))^m \to \mathcal{O}_X$ with locally free kernel. Thus in $K^\bullet(X)$

$$mEL^{-n} = 1 + F.$$

The corresponding γ-relation shows that $1 - EL^{-n}$, and therefore $L^n - E$, is nilpotent. Since $E - 1 = (L^n - 1) - (L^n - E)$, and since $L^n - 1$ is also nilpotent for n large, the assertion follows.

Proposition 6.2. Let R be an augmented sub-λ-algebra of $K^\bullet(X)$, generated by the classes of finitely many sheaves. Then the λ-ring filtration of R is discrete and $\mathrm{Fil}^1 R$ is nilpotent. Moreover, R is a finite module over its image in $H^0(X, \mathbb{Z})$.

After reducing to constant ranks, R is generated by finitely many elements $x_i = E_i - \varepsilon(E_i)$ and their γ-operations. Proposition 6.1 shows that all these elements are nilpotent. Hence the augmentation ideal of R is nilpotent; only finitely many monomials in the x_i's and the $\gamma^j(x_i)$'s remain. This gives both discreteness and finiteness.

Corollary 6.3. Let A be a commutative ring. An element y of $K^\bullet(X) \otimes_{\mathbb{Z}} A$ is invertible if and only if its augmentation is invertible. In particular, the class of every nowhere-zero locally free sheaf of finite type becomes invertible in $K^\bullet(X) \otimes_{\mathbb{Z}} A$.

Indeed, the augmentation ideal is nil.

Corollary 6.4. Let X be quasi-compact with an ample sheaf, and let $f : X' \to X$ be proper and perfect. Assume either that f is projective or that X is noetherian, so that the finiteness theorem applies. If there is an element $x' \in K^\bullet(X') \otimes A$ such that the augmentation of $f_*(x')$ is invertible, then

$$f^* : K^\bullet(X) \otimes A \longrightarrow K^\bullet(X') \otimes A$$

is injective. Indeed, by the projection formula,

$$f_*(f^* y \cdot x') = y \cdot f_*(x'),$$

and $f_*(x')$ is invertible by 6.3.

6.5. The codimension filtration

Assume now that X is noetherian of dimension d, and has an ample sheaf. Define a filtration $K^\bullet(X)^i$ as follows: an element $x \in K^\bullet(X)$ lies in $K^\bullet(X)^i$ if, for every closed subscheme $Y \subset X$, it can be represented by a perfect complex $M^\bullet(Y)$ such that

a) $\mathrm{cl}(M^\bullet) = x$;

b) $\mathrm{codim}(\mathrm{Supp}\, H^j(M^\bullet) \cap Y, Y) \geq i + j$, and $H^j(M^\bullet) = 0$ for $j \gg 0$.

These $K^\bullet(X)^i$'s are additive subgroups.

Proposition 6.6. The filtration of 6.5 is a ring filtration, and $K^\bullet(X)^{d+1} = 0$.

If x and x' are represented by perfect complexes $M^\bullet$ and $M'^\bullet$ satisfying the above codimension estimates, then xx' is represented by $M^\bullet \otimes M'^\bullet$. The support of $H^n(M^\bullet \otimes M'^\bullet)$ is contained in the union of the intersections of supports with total degree n, and the codimension estimate

follows from EGA 0_{IV}, 14.2.2.3. Finally $K^\bullet(X)^{d+1} = 0$, because a support in codimension greater than d is empty.

Lemma 6.7. Let $X = \operatorname{Spec} A$ be affine noetherian, let $x_1, \dots, x_n$ be finitely many points of X, and let E be invertible. There exists a section $s \in \Gamma(X, E)$ which is a basis of E_{x_i} for every i.

The proof uses closed specializations x_i' with distinct maximal ideals $\mathfrak{m}_i$, the isomorphisms $M/\mathfrak{m}_i M \simeq A/\mathfrak{m}_i$, for $M = \Gamma(X, E)$, and Nakayama's lemma.

Lemma 6.8. Let X be noetherian with an ample sheaf L, let E be invertible, and let $x_1, \dots, x_n$ be points of X. There exists an integer N such that, for every $k \geq 1$, $E(kN)$ has a global section which is a basis at every x_i.

Choose a power of the ample sheaf and a section whose non-vanishing locus is affine and contains all the x_i's; apply Lemma 6.7 there, and extend after multiplying by a further power.

Theorem 6.9. Let X be a noetherian scheme of dimension d with an ample sheaf. Then

$$\operatorname{Fil}^{d+1} K^\bullet(X) = 0,$$

and therefore $(\operatorname{Fil}^1 K^\bullet(X))^{d+1} = 0$.

First, if E and E' are invertible, with classes still denoted E, E', then $E - E' \in K^\bullet(X)^1$. For a closed $Y \subset X$, choose one point in each irreducible component. Lemma 6.8 gives morphisms from suitable negative powers of the ample sheaf to E and E' which are isomorphisms at those points. The two-term complex built from these morphisms has class $E - E'$, and is acyclic at the chosen generic points of Y; hence its cohomology supports have codimension at least 1 in Y.

Now take $x \in \operatorname{Fil}^{d+1} K^\bullet(X)$. It is enough to treat products

$$\gamma^{i_1}(E_1 - F_1) \cdots \gamma^{i_k}(E_k - F_k), \qquad \sum i_j \geq d + 1,$$

where the E_i, F_i are represented by locally free sheaves of the same constant rank. Pull back to the product of the flag bundles of these sheaves. The pullback is injective on $K^\bullet$, and each class splits into sums of invertible classes. For invertible classes ξ, η,

$$\gamma_t(\xi - \eta) = \frac{\gamma_t(\xi - 1)}{\gamma_t(\eta - 1)} = \frac{1 + (\xi - 1)t}{1 + (\eta - 1)t},$$

so

$$\gamma^i(\xi - \eta) = (-1)^{i-1}(\xi - \eta)(\eta - 1)^{i-1} \in K^\bullet(X')^i.$$

Thus the pullback of x belongs to $K^\bullet(X')^{d+1}$. Multiplication by a basis element of $K^\bullet(X')$ over $K^\bullet(X)$ of relative codimension r gives an element of $K^\bullet(X')^{d+1+r} = 0$, since $\dim X' = d + r$. The basis property and injectivity then give $x = 0$.

Problem 6.10. Under the hypotheses of Theorem 6.9, is it true that for every k one has

$$K^\bullet(X)^k = \operatorname{Fil}^k K^\bullet(X)?$$

Exposé VII. Regular immersions and the computation of $K^\bullet$ of a blow-up scheme

by Pierre Berthelot

1. Generalities on regular immersions

The classical notion of regular immersion (EGA IV 16.9.2) proves inadequate in the non-noetherian case. We shall define a weaker notion, one which gives the desired properties, and which is equivalent to the usual definition in the noetherian case.

Definition 1.1. Let A be a commutative ring, let E be a projective A-module of finite type, and let $u : E \to A$ be an A-linear homomorphism. We say that u is *regular* if the Koszul complex $\mathrm{K}(u)$ defined by u is acyclic in dimensions > 0, and hence is a resolution of $B = A/u(E)$.

Recall that the Koszul complex associated with u is the graded A-module $\bigwedge(E)$, with boundary the interior multiplication by u, regarded as an element of the dual $\check{E}$. This boundary is an antiderivation of degree -1, equal to u on E.

Lemma 1.2. Let $u : E \to A$ be regular. Let A' be an A-algebra and let $u' : E' \to A'$ be obtained from u by base change; suppose that u' is regular. Put $J = u(E)$, $J' = JA' = u(E')$. For every $n \geq 0$ one has

$$J^n/J^{n+1} \otimes_A A' \xrightarrow{\sim} J'^n/J'^{n+1}, \tag{1.2.1}$$

$$\mathrm{Tor}_i^A(J^n/J^{n+1}, A') = 0 \quad (i \geq 1), \tag{1.2.2}$$

$$J^n \otimes_A A' \xrightarrow{\sim} J'^n, \tag{1.2.3}$$

$$\mathrm{Tor}_i^A(J^n, A') = 0 \quad (i \geq 1). \tag{1.2.4}$$

First assume that the modules J^n/J^{n+1} are projective over $B = A/J$. Since J is of finite type they are locally free of finite type over B. The assertions are checked pointwise on $\mathrm{Spec}(A)$, so that one may suppose A local and $u(E) \subset \mathrm{rad}(A)$. Then J^n/J^{n+1} is free over B, and (1.2.2) is equivalent to $\mathrm{Tor}_i^A(B, A') = 0$ for $i \geq 1$. This follows by computing with the Koszul resolution $\mathrm{K}(u)$, since after tensoring with A' it becomes $\mathrm{K}(u')$, acyclic in positive degrees.

The exact sequences

$$0 \to J^n/J^{n+1} \to A/J^{n+1} \to A/J^n \to 0, \qquad 0 \to J^n \to A \to A/J^n \to 0$$

then give (1.2.1), (1.2.3), and (1.2.4) by induction on n. It remains to know that J^n/J^{n+1} is projective over B. Locally one reduces to $E = A^d$, with u given by $f_1, \ldots, f_d$, and to the universal homomorphism $\mathbb{Z}[T_1, \ldots, T_d]^d \to \mathbb{Z}[T_1, \ldots, T_d]$. Since the sequence $(T_1, \ldots, T_d)$ is regular, the conclusion follows by base change.

Proposition 1.3. Let A be a ring, E a projective A-module of finite type, $u : E \to A$ a regular homomorphism, and $J = u(E)$. Then J is quasi-regular: J is of finite type, J/J^2 is a projective A/J-module of finite type, and the canonical homomorphism

$$\mathrm{Sym}_{A/J}(J/J^2) \longrightarrow \mathrm{gr}_J(A) = \bigoplus_{n \geq 0} J^n/J^{n+1} \tag{1.3.1}$$

is an isomorphism. This is obtained from the preceding proof, again by reduction to the universal polynomial case.

Definition 1.4. Let (X, A) be a commutatively locally ringed site, let E be an A-module locally free of finite type, and let $u : E \to A$ be A-linear. We say that u is regular if $\mathrm{K}(u)$ is acyclic in degrees > 0. If J is an ideal of A, we say that J is regular if, locally on X, it is the image of a surjective regular homomorphism from a free A-module of finite type.

Let $i : Y \to X$ be an immersion of preschemes. If U is an open subset of X containing $i(Y)$, and if i is a closed immersion into U, then i is said to be regular if the ideal defining $i(Y)$ in $\mathcal{O}_U$ is regular. This condition is independent of U, and regularity may be tested in a neighbourhood of every point.

The definition replaces here that of EGA IV 16.9.2, and in the noetherian case the two definitions are equivalent. A closed immersion locally defined by a regular sequence is regular, and a regular immersion is quasi-regular by Proposition 1.3. A minimal system of generators of an ideal J at a point is a family whose images form a basis of $J_x \otimes k(x)$; regularity is equivalently the local acyclicity of the corresponding Koszul complex. If J is of finite type and J/J^2 is locally free, these systems correspond to local bases of J/J^2.

Proposition 1.5. If $i : Y \to X$ is regular, it remains regular after every flat base change. Conversely, i is regular if and only if it is so locally for the faithfully flat quasi-compact topology.

Definition 1.6. If $i : Y \to X$ is defined by an ideal J, the $\mathcal{O}_Y$-module J/J^2 is the conormal sheaf of Y in X, denoted $N_{X/Y}$. If i is regular it is locally free of finite type, and its rank is the codimension. For closed immersions $Z \xrightarrow{j} Y \xrightarrow{i} X$ one has the exact conormal sequence

$$j^* N_{X/Y} \longrightarrow N_{X/Z} \longrightarrow N_{Y/Z} \longrightarrow 0. \tag{1.6.1}$$

Proposition 1.7. Let $i : Y \to X$ and $j : Z \to Y$ be immersions. If i and j are regular, then $i \circ j$ is regular and the conormal sequence, completed by 0 on the left, is exact. If $i \circ j$ and i are regular and if this sequence is exact and locally split, then j is regular. If X is noetherian and if $i \circ j$ and j are regular, then i is regular at the points of Z.

Locally, write $X = \mathrm{Spec}(A)$, $Y = \mathrm{Spec}(B)$, $Z = \mathrm{Spec}(C)$, with $B = A/I$ and $C = B/K$. Choosing liftings $f_1, \ldots, f_n$ of a basis of I/I^2 and $g_1, \ldots, g_m$ of a basis of K/K^2, one obtains the diagram

$$\begin{array}{ccc} A_0 = \mathbb{Z}[T_1, \ldots, T_{n+m}] & \longrightarrow & A \\ \downarrow & & \downarrow \\ B_0 = \mathbb{Z}[T_1, \ldots, T_m] & \longrightarrow & B \\ \downarrow & & \downarrow \\ C_0 = \mathbb{Z} & \longrightarrow & C, \end{array} \tag{1.7.1}$$

Therefore:

$$\begin{aligned} i \text{ regular} &\iff \forall i \geq 1, \quad \mathrm{Tor}_i^{A_0}(B_0, A) = 0, \\ i \circ j \text{ regular} &\iff \forall i \geq 1, \quad \mathrm{Tor}_i^{A_0}(C_0, A) = 0, \\ j \text{ regular} &\iff \forall i \geq 1, \quad \mathrm{Tor}_i^{B_0}(C_0, B) = 0. \end{aligned} \tag{1.7.2}$$

One then uses the transitivity spectral sequence

$$E^2_{pq} = \mathrm{Tor}_p^{B_0}(C_0, \mathrm{Tor}_q^{A_0}(B_0, A)) \Rightarrow \mathrm{Tor}_n^{A_0}(C_0, A). \tag{1.7.3}$$

This gives the first two assertions; the noetherian assertion is that of EGA IV 19.1.5, with the definitions identified in the noetherian case.

Proposition 1.8. Let X be a scheme, E a locally free $\mathcal{O}_X$-module of finite type, $u : E \to \mathcal{O}_X$ a regular homomorphism, and $J = u(E)$. Let Y denote the closed subscheme of X defined by J, let X' be the scheme obtained by blowing up Y, let $P = \mathbf{P}(E)$ be the projective bundle

associated with E, and let $p : P \to X$ be the structural morphism. On P consider the canonical exact sequence

$$0 \to F \to p^*E \to \mathcal{O}_P(1) \to 0, \tag{1.8.1}$$

and the composite morphism

$$v : F \longrightarrow p^*E \xrightarrow{p^*(u)} \mathcal{O}_P.$$

Then:

1. the formation of X' commutes with every base change $f : T \to X$ such that $f^*(u)$ is regular;

2. the closed immersion $j : X' \to P$ defined by the surjective homomorphism

$$\mathcal{S}(E) \longrightarrow \bigoplus_{n\geq 0} J^n$$

defined by u in degree 1 is a regular immersion, its ideal being the image of the regular morphism v. In particular, if $\operatorname{codim}(i)$ is constant, then $\operatorname{codim}(j) = \operatorname{codim}(i) - 1$;

3. the $\mathcal{S}(E)$-module $\bigoplus_{n\geq 0} J^n$ is perfect as a graded $\mathcal{S}(E)$-module, i.e. locally there is a finite graded resolution of $\bigoplus_{n\geq 0} J^n$ by graded $\mathcal{S}(E)$-modules locally free of finite type.

For (i), since $X' = \operatorname{Proj}(\bigoplus_{n\geq 0} J^n)$, the result is an immediate consequence of the relations (1.2.3) and of EGA II.

For (ii), the asserted properties being local on X, one may suppose that $X = \operatorname{Spec}(A)$, and moreover that E is free on X. We first prove the assertion in the standard case

$$A = \mathbb{Z}[T_1, \ldots, T_d],$$

where E is given the basis $e_1, \ldots, e_d$, with $u(e_i) = T_i$. Then

$$P = \operatorname{Proj}(\mathbb{Z}[T_1, \ldots, T_d, X_1, \ldots, X_d]),$$

the grading being taken with respect to the X_i. To show that v is a regular morphism whose image is the ideal of j, it suffices to do so locally on P, hence on the open sets $D_+(X_i)$; let us place ourselves, for instance, on $D_+(X_1)$. Then $p^*(E)$ is defined by the module

$$\mathbb{Z}[T_1, \ldots, T_d, X_2/X_1, \ldots, X_d/X_1] \otimes E,$$

and $\mathcal{O}_P(1)$ by

$$\mathbb{Z}[T_1, \ldots, T_d, X_2/X_1, \ldots, X_d/X_1],$$

the canonical morphism sending e_i to X_i/X_1 for every i. Thus F has as a basis the elements

$$e_i - e_1 X_i/X_1 \qquad (i > 1).$$

One has

$$v(e_i - e_1 X_i/X_1) = T_i - T_1 X_i/X_1; \qquad T'_i = T_i - T_1 X_i/X_1.$$

Since the sequence of the T_i is regular in

$$\mathbb{Z}[T_1, \ldots, T_d, X_2/X_1, \ldots, X_d/X_1],$$

the same is true of the sequence $T_1, T'_2, \ldots, T'_d$, which is obtained from it by an invertible matrix, and therefore also of the extracted sequence $T'_2, \ldots, T'_d$.

It remains to show that the T_i' generate the ideal of j. In $\bigoplus_{n\geq 0} J^n$, for $m \leq p$, we shall write $x^{(m)}$ for the element x of J^p, considered as being of degree m. Over $D_+(X_1)$,

$$X' = \operatorname{Spec}\left(\left(\bigoplus_{n\geq 0} J^n\right)_{(T_1^{(1)})}\right),$$

and j is defined by the morphism sending X_i to $T_i^{(1)}$. In this morphism the image of T_i' is

$$T_i^{(0)} - T_1^{(0)}T_i^{(1)}/T_1^{(1)} = \left((T_iT_1)^{(1)} - (T_1T_i)^{(1)}\right)/T_1^{(1)} = 0.$$

Thus the T_i' belong to the ideal of j. Since every element of

$$\mathbb{Z}[T_1, \ldots, T_d, X_2/X_1, \ldots, X_d/X_1]$$

can be expressed as a polynomial in $T_1, T_2', \ldots, T_d', X_2/X_1, \ldots, X_d/X_1$, it suffices, in order to show that the T_i' generate the ideal of j, to show that no non-zero element of

$$\mathbb{Z}[T_1, X_2/X_1, \ldots, X_d/X_1]$$

belongs to the ideal of j. This amounts to showing that the homomorphism

$$\mathbb{Z}[T_1, X_1, \ldots, X_d] \longrightarrow \bigoplus_{n\geq 0} J^n$$

is injective, since $T_1^{(1)}$ is not a zero divisor in $\bigoplus_{n\geq 0} J^n$. If one grades $\mathbb{Z}[T_1, X_1, \ldots, X_d]$ by assigning degree 0 to T_1 and degree 1 to the X_i, the kernel of the homomorphism in question is a graded ideal. But it is contained in the kernel of the composite homomorphism

$$\mathbb{Z}[T_1, X_1, \ldots, X_d] \longrightarrow \bigoplus_{n\geq 0} J^n \longrightarrow A,$$

the last homomorphism being defined in degree n by the injection of J^n into A. The kernel of the composite homomorphism is the principal ideal generated by $X_1 - T_1$, which, by integrality, contains no non-zero homogeneous element. Therefore the first homomorphism is injective, which completes the proof in this case.

Return to the general case where A is arbitrary, with E still assumed free on X. Put index 0 on the special case just treated. By part (i), the situation under consideration is obtained from the preceding one by the base change $A_0 \to A$, where the homomorphism $A_0 \to A$ is defined by choosing a basis of E, its image $f_1, \ldots, f_d$ in J, and sending T_i to f_i. Put

$$B_0 = \left(\bigoplus_{n\geq 0} J_0^n\right)_{(T_1^{(1)})}, \qquad B = \left(\bigoplus_{n\geq 0} J^n\right)_{(f_1^{(1)})}.$$

Then $B = B_0 \otimes_{A_0} A$, and the Koszul complex defined by $v : F \to \mathcal{O}_P$ is obtained by base change from the Koszul complex defined by v_0. Since the latter is a projective resolution of B_0 on a suitable open set, the homology groups of $K_\bullet(v)$ are, on this open set, the groups

$$\operatorname{Tor}_i^{A_0}(A, B_0).$$

These are the components of degree 0 of

$$\operatorname{Tor}_i^{A_0}\left(A, \left(\bigoplus_{n\geq 0} J_0^n\right)_{T_1^{(1)}}\right) = \left(\bigoplus_{n\geq 0} \operatorname{Tor}_i^{A_0}(A, J_0^n)\right)_{T_1^{(1)}}.$$
